A process of manufacturing steel which consists in preparing an ore charge containing a carburizing carbon, a reducing carbo-hydrate, and a suitable percentage of manganese dioxide and a fluxing material suitable to produce a liquid slag, all in a fine state of division and intimately

mixed, and then heating the ore charge thus prepared to reduce it and to purify and carburize the metal.

COPPER-CONVERTER.—No. 919,199. Frank E. Marcy, Salt Lake City, Utah.

In a converter the combination of a cylindrical drum, an end of said drum provided with a continuous tread to permit complete inversion of the converter, the tread being of a diameter at least equal to the smallest diameter of said cylinder, friction wheels coacting with the tread for supporting the converter, and a top secured to the drum in a plane free from intersection with the tread.

MELTING-FURNACE.—No. 918,150. James E. Hewitt, Newark, New Jersey.

A melting-furnace comprising a shell, an inner combustion chamber separated from the shell by an air space, and a crucible supporting hollow block in the chamber bottom, said block having a seat to support a crucible, side openings, and convex top walls arranged to deflect the fuel and products of combustion to the said openings.

ORE-SEPARATOR.—No. 919,246. Elmer A. Ross, Ticonderoga, New York.

In a separator of the character described, the combination with an elongated classifying conduit having a plurality of sections, each adapted to collect a separate grade and each provided with discharge means comprising pipes converging downwardly into a single conduit, secondary discharge pipes connecting the classifying conduit and the converging pipes, and means for forcing fluid and suspended solids through the classifying conduit.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

CONTRACT TO CONVEY MINING CLAIMS—CONSTRUCTION.

A contract to convey certain specified placer mining grounds, described as part patented and part mineral entries for which receiver's receipts had been issued, "patent not yet issued, but to be issued," and the vendee was afterward put in possession in accordance with the contract. Such contract was construed to be one to convey such title to the several claims, legal or equitable, as the seller then had, and that this was fully understood by the parties to the contract. The words "patent not yet issued, but to be issued," were construed to be merely descriptive and not to be words of covenant and did not bind the seller to convey a patent title. The fact that patents for such unpatented claims had not been issued at the time the purchaser was to make final payment and receive the deed did not afford ground for rescission by him.

Nelson v. Wood Placer Mining Co., 167 Federal 206, Nov. '08.

MONOPOLIES—COMBINATIONS BY MINING CORPORATIONS.

A Michigan mining corporation engaged in mining and refining copper wholly within that State, by purchasing stock and obtaining proxies from other stockholders secured a voting control of a majority of the stock of a similar corporation operating adjoining mines. The purchasing corporation proposed to use such control to place in its directory a majority from its own board of directors. It was held to have the right to do this under the laws of the State, and it did not directly or necessarily affect interstate or foreign commerce and that such control was not of itself illegal as a condition in restraint of trade in violation of the Sherman Anti-Trust Act, especially in the absence of proof of an unlawful intent to so use its power as to bring about the prohibited restraint or monopoly and not in a lawful way to use it in an economical management of both companies.

Bigelow v. Calumet & Hecla M. Co., 167 Federal 704, 721, Oct. '08.

OIL LEASE—RIGHTS OF LESSOR.

In an action to recover land from trespassers who had drilled oil wells thereon and for an accounting for oil taken, where it is shown that such trespassers had gone into possession under a void assignment of a lease executed by the complainant and had expended large sums of money in a mistaken belief that they had a lawful right to enter upon such land and drill the wells, they were not required to account for the full value of the oil taken after it was produced, but only for its value in the ground as measured by the royalty complainant was to receive under the lease.

Turner v. Seep, 167 Federal 646, Feb. '09.

OIL AND GAS LEASE ON INDIAN LANDS—ASSIGNMENT.

An oil and gas lease executed by an Indian in the Indian Territory on a form prescribed by the Interior Department expressly provided that no sub-lease or assignment of any interest therein should be made without the written consent of the lessor and the Secretary of the Interior, and any such attempted assignment or transfer without such consent should be void. A subsequent regulation of the Interior Department which contained no requirements of the consent of the lessor in such case was not sufficient to validate a prior assignment of such a lease made without the lessor's consent.

Turner v. Seep, 167 Federal 646, Feb. '09.

POSSESSION OF MINING CLAIM—PRESUMPTION AND BURDEN OF PROOF.

The owner in fee of a patented lode mining claim is presumed to be in possession of the surface included in the lines of the location, and the burden of proving the contrary rests upon one claiming any part thereof by adverse possession.

Original Consol M. Co. v. Abbott, 167 Federal 681, Aug. '08.

Exhaust Steam Low-Pressure Turbines.

That the economies possible in the use of low-pressure turbines are not confined to the highly efficient power plants of the East, is apparent in the contract recently placed by the Potlatch Lumber Co. for a 600-kw. Westinghouse exhaust steam-turbine to be installed in the company's central power-plant at Potlatch, Idaho. There are at present placed in this plant one rope-driven Corliss engine and a 100-kw. high-speed triple engine, driving a generator. The low-pressure turbine will take steam at about 15 lb. absolute from both these units, and some other auxiliaries generating power. Arrangements have also been made for the operation of this unit for lighting for the mill and the surrounding town. The equipment ordered also includes a Westinghouse Leblanc condenser, designed for carrying a 20-in. vacuum. At the Potlatch plant refuse from the saw-mill is used entirely for fuel at practically no cost. It is thus apparent that the capacity of the plant has been greatly increased with practically no cost except the charges on the low-pressure turbine installation. This feature of exhaust-turbine work is being rapidly appreciated by managers of power-plants in every line of industry, resulting in a number of orders for equipments of this character.

German Copper Statistics.

L. Vogelstein & Co., of New York, give the following figures of German consumption of foreign copper for the months January to June 1909:

| | Tons. |
|-------------------------|--------|
| Imports of copper | 80,061 |
| Exports of copper | 3,913 |

Consumption of copper..... 76,148

as compared with consumption during the same period in 1908 of 79,090 tons. Of the above quantity 73,416 tons were imported from the United States.

Commercial Paragraphs.

THE C. O. BARTLETT & SNOW Co., Cleveland, Ohio, advises that it has lately received an order from the Philadelphia & Reading Coal & Iron Co., for a Greene self-dumping car-haul to be installed at the Burnside colliery.

THE KEYSTONE PLACER DRILL Co., Beaver Falls, Pennsylvania, has furnished to the City of Nappanee, Indiana, a double-stroke geared pump, doubling the capacity of the municipal water-supply plant. The same company also had the contract for boring the well in which the pump was hung.

Catalogues Received.

THE J. GEO. LEYNER ENGINEERING WORKS Co., Littleton, Colorado, in its Bulletin 1008 lists and describes the complete line of drill-sharpening machines manufactured by that company.

THE D. D. DEMAREST Co., San Francisco, has just published an interesting circular on the subject of Cornish pumps. It is worth reading by anyone who is at all interested in pumping.

AN ILLUSTRATION of record-time execution of a rush order for head-gate equipment required by the Anaconda Copper Mining Co. was given by the Dodge Manufacturing Co., Mishawaka, Ind. There were 13 units of head-gates, with frames and geared operating mechanism. The head-gates and frames, 40 ft. long, were of structural steel and weighed a total of 75 tons. The operating mechanism was of cast-iron framing, with cast gears, making an aggregate of 150 tons. The contract was taken April 3, '09, guaranteeing shipment in four weeks. Drawings and specifications were furnished by the Anaconda engineers. Patterns had to be made for the castings, which were special. This work was done, castings made, and the assembling well under way on April 14. The entire job was shipped to Montana April 23, thus making delivery in 20 days, or eight days less than the contract-time.

EDITORIAL.

WHILE nothing is certain until it is done, we are disposed to alter an opinion expressed editorially last week concerning changes in the new Mexican mining law as passed by the Deputies. The indications that the statute as it stands will be confirmed by the Senate are so strong as to leave little doubt as to the result.

STYLE is opposed to haphazard. In technology, as in every department of human work, it is a matter of convenience to use recognized forms of expression; it leads to clearness and accuracy. To this end the MINING AND SCIENTIFIC PRESS has endeavored to crystallize out of varied usage a standard which should serve as a correct medium. It is pleasing to note that Messrs. W. A. Caldecott, Ralph Stokes, J. E. Thomas, and other members of the Chemical, Metallurgical & Mining Society of South Africa, in issuing a style-sheet for the forthcoming review of local Rand practice, have stipulated that the terms 'sand', 'slime', 'concentrate', 'residue', and 'tailing' should be used in the singular when a plural meaning is not distinctly involved, thus accepting the system which we have advocated and employed.

IT was not with any wish to defraud Messrs. W. W. Mein and W. K. Betty of credit that we attributed to Mr. W. A. Caldecott, some weeks ago, the honor of having proposed the crushing of Rand banket ore in cyanide solution. Mr. Caldecott will not begrudge this peacock feather. There is so much plumage of the royal bird passed around at Johannesburg that everyone seems decorated, and the Chemical, Metallurgical & Mining Society of South Africa keeps before the world the honors achieved by its elect. The function of a local organization in expanding the influence of a group of men, so that it becomes felt all round the world, was never better illustrated than by this Society. It is not the bigness and the richness of the Rand that has accomplished this result; it is because the Society as a body has taken a high position for severe critical discussion, and has not permitted the debates to be used for mere personal puffery.

AMERICAN participation in the Hankow-Sze-Chuen railroad loan was arranged through the tact and skill of the chargé d'affaires at Pekin, Mr. Henry P. Fletcher, who has thus displayed diplomatic qualities worthy of substantial recognition. The amount of the loan has been increased from \$27,500,000 to \$30,000,000, of which American bankers are privileged to subscribe for one-fourth, the other three-quarters being adjudged to English, French, and German capitalists. The settlement ar-

ranged by Mr. Fletcher carries with it equal opportunity for Americans to supply material of construction for both the Sze-Chuen and the Canton lines, together with the right to participation in all future loans. The opposition to American influence in China has been strong, perhaps quite as intense from England and France as from Germany, although the open hostility has been chiefly Teutonic. The strategic position of the United States with reference to China is such that ultimate dominance of the situation from a commercial standpoint seems inevitable. So it seemed to Europe, and hence the victory won by Mr. Fletcher was against severe odds that render it, and the man who achieved it, notable.

Taxing Unoperated Mineral Land.

Our Denver correspondent informs us that Mr. John F. Shafroth, the Governor of Colorado, will remove from office the assessor of Huerfano county for assessing as grazing land the areas controlled by coal companies outside of the portions actually involved in mining operations. If this step is taken because of illicit transactions between the assessor and the coal companies it is justifiable; otherwise it would seem to be drastic. The principle involved is not precisely that of taxing the unearned increment. No man can definitely affirm the amount of such unearned increment until a transfer of title occurs. Thus is seen the virtue of the laws prevailing in certain countries whereby real estate is not taxed directly, but an amount, usually five per cent of the purchase price, is taken when the property changes hands. A bill was presented at the last session of the British Parliament for covering the identical point which has disturbed Governor Shafroth in Colorado. A basis for adjustment of the tax was found so difficult to establish, and the burden it would entail was proved to be so onerous, that in spite of the urgent need of revenue, the project was abandoned. Taxation is essentially a contribution out of earnings. Incidentally it serves as a deterrent to the locking up of resources; but manifestly the simultaneous utilization of the great reserves of mineral deposits is impossible. These are held in trust for future generations. The ascertainment of their extent and richness, and their control by effective working organizations, is a distinct contribution to the welfare of the future. It permits systematic exploitation along economic lines, and thus leads away from wasteful methods. To tax such inactive resources is not unlike an attempt to levy a tax upon the future. As our correspondent remarks, the questions involved may easily give rise to widely differing opinions. Undoubtedly it is an evasion of responsibility, even when honestly done, to assess coal-areas as grazing land. The case illustrates the need of determining an equitable procedure in these matters. What applies in the case which has arisen in Huerfano county is equally applicable to large deposits of metallic ores. It comes into prominence in connection with the vast low-grade copper deposits which are being developed with startling rapidity in the West. Eleven companies have over 250 million tons of ore proved, containing a recoverable copper content of

10 billion pounds. This is as much as the whole United States would produce at the present rate of output in nearly twelve years. Manifestly this reserve will furnish a basis for mining for many decades. Who can say what the actual value of these reserves would be today? In order to answer such a question one must know the cost of mining and reduction, and the market price, in the distant future.

Smelter Fume and Equity.

When a smelters' paradise is established it will have to be in a land too desert to support a farmer—something dryer than now exists within these United States. The ever recurring difficulty over fume has now become serious in Shasta county, California, and war is imminent. At least diplomatic relations have been severed, and the Farmers' Protective Association has issued an ultimatum. A committee was recently appointed to confer with the smelters, and on the strength of a report submitted to the organization at its meeting in Anderson the other day it was "Resolved: that the Shasta County Farmers' Protective Association does hereby absolutely demand that the infliction of damages by smelter smoke and fumes must cease; and that said smelters be at once sent a copy of this resolution with the demand that on or before October 1, next, some tangible proof shall be submitted to this Association that immediate steps are to be taken to stop said fume and smoke nuisance." That is sufficiently mandatory. It would have been interesting at the same time to have had expert advice as to means for complying with the demand. It is physically possible to abate the smelter-fume difficulty, but it has not yet proved economically possible to do it. The smelters are open to negotiation with anyone who can produce an efficient remedy, and efficiency involves financial feasibility. Lawsuits do not attract the owners of smelting works; they trench heavily upon and absorb profits; and relief through any adequate technical process would be most welcome. Many kinds of apparatus have been invented to cure the evil, but the fundamental principles which can be applied are few. These fall under four heads: the cooling of the gases to a point which will cause the condensation of the sulphuric anhydride (SO_3); the elimination of the SO_3 by washing with water; the precipitation of this substance by the electric discharge; and neutralization. This all sounds simple, and the non-technical man might order instant relief by the application of one of these principles, and then wonder why it didn't work. It has taken a long time for Darius Green to achieve vindication. The only difficulty in flying was to obtain sufficient velocity with a sufficient spread of wing, but a couple of generations have passed since the verdant aviator came to grief; poor Langley died disappointed after all his splendid contributions to the physics of flight; and it was only a week or two ago that M. Blériot invaded England in a flying machine. It takes time to work out the problems that confront men, and until the solution comes we have to do the next best thing, which is to determine what is most desirable for the greater number. In the end utilitarianism rules. This is not a world of sentiment, but a world

to live in, and all cannot be happy in it at the same time, which we believe can be demonstrated from the monuments of Egypt, and from the somewhat violent justice of the code of Hammurabi. The greatest good for the greatest number has always determined the ultimate course of society, individualistic rights to the contrary notwithstanding. We are aware that certain decisions of the Federal Courts have recently sustained the right of the individual as against that of large corporations and the great number of people dependent upon them for a living. The most recent decision along this line was that of the Supreme Court of Arizona in the case of the Arizona Copper Company *v. Gillespie*, which affirmed the right of the individual, in opposition to the principle enunciated by Judge Hunt of Montana in *Bliss v. Anaconda Copper Mining Company*. At the time the Arizona decision was handed down we pointed out that the decision of the Supreme Court of the United States in a famous case (*New York City v. Pine*) seemed to establish an equitable basis which recognized both the right of the individual and that of the public. In effect that was the necessity of due diligence on the part of the individual. If he establishes himself in the track of possible damage which could have been foreseen, he has done so at his own risk: if he be already established it is his part to foresee possible well known perils from other industries that are proposed in his neighborhood, and it is his duty to protest; if due diligence has been observed and unforeseen damage result there is the usual remedy at law. Whether that should also involve an injunction is a question which would be determined by each judge, and no man can prophesy what would be his point of view. Ordinarily the preponderance of interest in terms of numbers would control. Preponderance of financial interest weighs less than that of the respective populations dependent upon the clashing industries. This seems to be equitable, and to satisfy the requirements of a rational utilitarianism which looks not toward any form of paternalism in government for a remedy. How far the people of Shasta county have considered these phases of the situation we are not informed. We think they may be leaning too heavily upon the principle which determined the decision of the Federal Court in the famous *débris* case of *Woodruff v. North Bloomfield Gravel Mining Company*. It is by no means certain that the temper of the courts would be found the same today. Our sympathies go out to the farmer as well as to the miner; and no one would more promptly call to account any corporation that was wilfully doing avoidable injury. But in this case, as in almost every other where this eternal fume-problem has become annoying, the farmer has been in a position to benefit more largely by the presence of the smelter than he could hope to do were the smelter driven away. For actual demonstrable injury sustained by reason of fume he can readily collect damages in court. So fully has this been recognized that it has been a regular procedure to assess and pay for such damages out of court. Furthermore it has become customary to ascertain the average damage caused over certain areas, and to commute this by cash payments on what are termed

'smoke-easements'. Thus may these difficulties be equitably adjusted if no attempt be made to over-reach and demand damages in such sums as might give rise to suspicion of blackmail.

Coming back to the technical difficulties in the case, we may point out that simple precipitation by cooling is not as easy as it looks. Sulphuric anhydride is evolved in considerable quantities in the roasting of any sulphides. This is the principal cause of damage. It is acrid, and corrosive. Uniting with water it forms sulphuric acid. The SO_3 itself is a white solid when condensed, but it begins to volatilize above a temperature of 59° Fahrenheit, and is completely volatile at 115° . These are low temperatures; too low in fact to give much motive-column for draft except in winter when the atmosphere outside of the chimney would be cold. In other words, mere length of flue is not enough, particularly in hot weather. Even if it were feasible to so cool the gases as to eliminate the SO_3 , the decrease of temperature would reduce the natural draft to such an extent as to require the application of power to move the flue-gases, and at once the economic element enters and baffles attempts to solve the problem in that manner.

Elimination of the SO_3 by water is also mechanically feasible, if done regardless of expense. Spraying, which looks so easy, has practically failed. It has been tried by our fathers and grandfathers for generations, and human ingenuity has exhausted every means to render it effective. Passing gas through water does not wash it. If anyone doubts that fact let him add more, for his personal edification, to the big sums that have been expended to reach that conclusion. A tower filled with coke, or broken rock of certain kinds, through which water trickles, will afford sufficient contact between the gases and the water to wash out soluble compounds. This, however, introduces enormous frictional resistance, reduces the temperature, and necessitates the application of power to move the gases. It comes back to a question of the thing that is economically possible. Electric precipitation has not yet been demonstrated successfully on a scale of such magnitude as to cope with the enormous volumes of gases issuing from large roasting furnaces. This is the Cottrell process, which may become the solution of the problem. Mr. F. G. Cottrell admitted his inability to adapt it in its present state to the conditions at Anaconda, Montana, as Mr. E. P. Mathewson testified some time ago before Judge Hunt. Neutralization of fume with volatilized zinc oxide has been applied by Mr. George W. Heintz at Bingham Junction with such success as to obtain a court decree permitting the smelter of the United States Smelting, Refining & Mining Company to operate. The adaptability of this system to general conditions, however, is not proved, and it is unsafe to argue too far from this isolated example. There is a heavy burden of proof devolving on the Shasta farmers to show that the smelters can obey their mandate without financial ruin. We commend once more to all concerned a careful consideration of the high principle of justice and equity involved in the decision in the case of *New York City v. Pine*.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

H. F. MARRIOTT is in Canada.
CHARLES BUTTERS is at Carlsbad.
R. B. MORTON has been in Denver.
J. H. CURLE went to Norway recently.
GEORGE OTIS SMITH was in San Francisco.
W. E. DEFTY has gone to Phoenix, Arizona.
H. FOSTER BAIN was at Central City, Colorado.
HENRY F. COLLINS is examining mines in Spain.
H. A. TITCOMB is on his way to western Siberia.
JAMES F. CALLEBREATH has been in San Francisco.
THOMAS H. LEGGETT was at Sutton Island, Maine.
R. H. BURBOWS has returned to Guanajuato, Mexico.
CHAS. T. LYSER has returned to Berkeley from Chloride.
ARTHUR K. ADAMS has removed to Santa Fé, New Mexico.
C. A. BRYANT has gone from Eagle, Alaska, to Kallispell, Montana.
J. W. FINCH has returned to Denver from Butte and the Couer d'Alene.
W. H. STORMS has returned from San Francisco to Sutter Creek, California.
DAVID MCCLUBE, Jr., is returning to California from a holiday in Europe.
LEWIS T. WRIGHT is expected in San Francisco on his return from London.
GEO. J. YOUNG, of the Mackay Mining School, Reno, Nev., was in San Francisco.
GARDNER F. WILLIAMS, who now lives at Washington, is on a visit to South Africa.
R. A. F. PENROSE has left San Francisco for Philadelphia, visiting Denver on the way.
ERNEST R. WOAKES is taking a holiday in London; he will return shortly to Linares, Spain.
J. E. THOMAS, of the Simmer & Jack, has been in London and is returning to Johannesburg.
ROBERT LINTON has returned to Los Angeles after examining iron properties in eastern Texas.
HOOPER & SPEAK, of London, have been appointed consulting engineers to the Famatina mine, Argentina.
GEORGE A. TWEEDY passed through San Francisco. He will visit New York before returning to Rosario, Sinaloa.
W. J. ADAMS has been examining the property of the Ruth Pierce Mining Co., at Horinotos, Mariposa county, California.
L. S. GRISWOLD, of the Missouri School of Mines, has been visiting Nevada and California. He is now in Clear Creek county, Colorado.
HORACE V. WINCHELL was among the passengers rescued from the wrecked S. S. *Ohio*, on August 26. He is on a journey to Alaska.
W. K. BETTY, of Messrs. Eckstein's metallurgical department, is visiting some of the chief gold-mining centres of the western United States.

The best manner of introducing hydraulic machinery into the Mexican market, according to Consul Thomas W. Voetter, of Saltillo, is by the maintenance of a representative in Mexico who will travel from place to place. By careful reading of the press, and from news which an able man would receive from acquaintances, a representative would learn of enough new enterprises in Mexico to keep him busy looking after them. If the home office should consider the expense of maintaining such a representative too great, it might join forces with one or two other firms which have allied lines, but not competing ones, so that the expenses of the joint representative could be divided. One good contract landed will pay the expenses of a good man for a long time, and one installation satisfactorily completed will be a good advertisement for another. Many foreign firms maintain agencies in the City of Mexico,

General Mining News.

ARIZONA.

COCHISE COUNTY.

The precipitating plant at the Copper Queen has been completed and the water turned through both upper and lower sets of troughs.—At a meeting of the stockholders of the Bisbee-Arizona Mining Co., it was decided to increase the stock from 1,000,000 to 2,000,000 shares.—The heavy motor for the new hoist in course of erection at the Irish Mag shaft of the Calumet & Arizona Mining Co. was hauled to the mine. The shaft is being retimbered and put in order for a new skip.

GILA COUNTY.

Hovland & Smith, of Duluth, have secured the control of the Black Warrior properties in the Globe district, for \$1,250,000, the largest part of which is cash, the rest bonds convertible into stock at par in the new company which is to be organized with a capital of \$2,500,000. The property is a producing one, shipping at present 100 tons of 10% copper ore per day. On a portion of the property an orebody has been opened for a distance of 700 ft., which is from 40 to 60 ft. wide, and explored to a depth of 150 ft. A narrow-gauge railroad connects the mine to the Warrior townsite and it is expected the Southern Pacific will build a spur to connect with the Miami line.—The Joe Bush shaft of the Inspiration company is down 385 ft., and from the 90-ft. point has been in ore that will average 3% copper. There are over 1600 tons of ore on the dump from this work. Of the nine drill-holes sunk on the property, all have cut ore that will average more than 3%.—At the Superior & Boston a force of 70 men is at work. The new hoist and compressor have been set up and a boiler-house and dry-room is in course of construction. The management expects to commence shipping ore about October 1.—The Arizona Commercial Copper Co. is to blow in its new plant the last of this month, and has advertised for bids to construct a number of cottages for its employees.—At the Arizona-Michigan cross-cuts are being driven to the veins on the 500-ft. level. N. A. Nelson is superintendent.—There are 25 men working on the Live Oak property driving a drift on the third level, and running cross-cuts into the ore. The east drift is in 80 ft., with a cross-cut 80 ft. in ore that averages 2½% copper.—A 15-ft. cross-cut from the 60-ft. level of the McEwen & Davidson group opened 2½ ft. of copper glance. Twenty tons of this material has been taken out for shipment to the Old Dominion smelter.—The upper adit of the Rye Copper Co., 16 miles from Payson, has opened a small body of copper ore. A lower adit, now in 325 ft., is being driven to cut the same vein at depth. It will require about 1000 ft. additional work for this to intersect the vein. H. S. Duncan is superintendent.

MARICOPA COUNTY.

Elliott & Drescher, of Prescott, have a contract to install a 5-ft. Huntington mill on the property of the Sunnyside Mining Co. in the Hassayampa district.

YAVAPAI COUNTY.

A syndicate has been formed to take over the Gold Note mine of A. D. Cupples, southwest of Congress. There is a 3-stamp mill on the property and the company plans to enlarge this and install heavier machinery at the mine.—A Butters filter is being installed in the plant at the Alvarado mine. A large amount of \$12 ore is blocked out in the upper levels and the same vein has just been opened at the 900-ft. level. E. W. Duffree is superintendent.—The Yarnell mine, 5 miles from Congress Junction, is to be re-opened and a new mill erected.—The Rincon mine is to be re-opened this fall.

The differences of the stockholders of the Stanton-Rich Hill Mining Co., at Stanton, have been adjusted and work at the mine is to be resumed shortly.—D. J. Sayer, of Denver, is to resume operations at the Churchill mine near Stanton.—The La Gracia Gold & Copper Mining Co. has commenced development work at its Red Bluff group 6

miles from Dewey. Samples from the property have assayed 20% copper, 8% cobalt, with some nickel, arsenic, and antimony. T. C. Jordan is manager.

CALIFORNIA.

AMADOR COUNTY.

The South Eureka Mining Co. is to install 20 additional stamps in its mill near Sutter Creek. The South Eureka company has been tramming a large portion of its ore to the Central Eureka mill having leased 20 stamps there.—Two new cables have been put on the reels at the Keystone mine that will enable the company to sink 600 ft. deeper. The foundation of the head-frame at the Oatton shaft has been strengthened and 20 stamps in the mill put in good condition. The company is grading for an addition to the mill that will contain 80 stamps. When this is completed the old mill will be dismantled and the old stamps replaced by heavier ones.—Webb Smith, superintendent of the Kennedy mine, and associates, are to prospect the Orr property north of Plymouth.—The mill at the Original Amador will be completed in a short time.

BUTTE COUNTY.

The Leggett No. 3 dredge has been completely dismantled and the machinery placed in a new boat which is now working on the Hulse and Savage properties near Palmero.

LOS ANGELES COUNTY.

On Friday afternoon, August 17, an informal reception was tendered by the members of the Los Angeles Chamber of Mines, to members of the Arizona Hassayampa Club, of Los Angeles, the Montezuma Club, of Goldfield, and the Sierra Madre Club, of Los Angeles, and to visitors generally from the mining districts of the Southwest and Old Mexico. An address of welcome to the visitors from the various mineral districts was tendered by Calvert Wilson, the president of the Chamber.

MARIPOSA COUNTY.

McClure Gregory is preparing to re-open the Tyro mine near Coulterville. The old shaft opened a 6-ft. vein at a depth of 650 ft., and drifts were run along this over 300 ft. There is a 10-stamp mill on the property which will be started at an early date.—Lessees of the Long Mary mine have started the mill on that property.

NEVADA COUNTY.

A. L. Shinn and C. L. Wilson have taken a bond on the McKinlay and Golden Slipper groups near Moore's Flat.—Ten additional stamps are to be started in the Idaho-Maryland mill shortly.

PLACER COUNTY.

A new adit has been started on the Hidden Treasure property. Harold Power is in charge of the work.—The Dewey claim has been bonded by a Denver firm which let a contract to drive the adit 100 ft. It will require 350 ft. additional work to cut the vein with this adit and the ore will be opened at a depth of 200 ft. W. R. Grant will have charge of the work.—The adit on the property of N. E. Davenport has cut the contact and opened some good ore.

PLUMAS COUNTY.

J. N. Turner, operating a lease on a portion of the Johnson-Graham mine, formerly known as the Plumas Eureka, has opened a shoot of ore that averages 3 ft. wide and assays from \$27 to \$104 per ton. The mine is within three miles of the Western Pacific's tracks, and is credited with a past production of \$15,000,000.

SAN BERNARDINO COUNTY.

The Foster Brothers and Patrick McCluskey have made arrangements with the Hart Townsite company to supply the necessary amount of water for the mill which they are to erect. A shaft is to be sunk on the high-grade ore recently discovered in an open-cut and a connection made with the 100-ft. level.—Operations are to be resumed at the Florence property in Hart this month. There is a large body of low-grade ore blocked out on the 180-ft. level, and it is understood that the company is to install a hoisting plant and erect a mill. J. C. Popper is manager.

SHASTA COUNTY.

The Western Exploitation Co. is installing an 18-hp. hoist at the Milkmaid mine in French Gulch.—At a meeting of the Farmers' Protective Association in Anderson, the committee appointed to interview the managers of the smelters reported that those officials would promise nothing definite. The Association, therefore, adopted the following resolution: "Resolved, That the Shasta County Farmers' Protective Association do hereby absolutely demand that the infliction of damages by smelter smoke and fumes must cease. And that said smelters be at once sent a copy of this resolution with the demand that on or before October 1, next, some tangible proof shall be submitted to this Association that immediate steps are to be taken to stop said fume and smoke nuisance."

SIERRA COUNTY.

(Special Correspondence).—The Kate Hardy has cut a shoot of ore running \$100 to \$5000 per ton. San Francisco people are interested.—The Oakland mine has uncovered a stringer of rich ore. The lower adit is expected to cut the vein at a depth of 350 ft.—A 6-ft. vein of milling ore is reported from the adit of the Slate-Castle-Jaffa group.—A raise will be driven from the adit of the South Fork mine to tap the channel traversing the South Fork and Maple Grove holdings.—The Acme Mining Co. is driving an adit to open its property. The vein has been cross-cut 35 ft. It is understood that a mill will be erected this fall.—W. T. Forsman, of Sacramento, has bonded the holdings of Foster & Squires for \$10,000, and has commenced active work.—At the Bellevue 35 men are working and good gravel is being extracted. London capitalists are interested.—The adit at the Gladstone is in 150 ft., and is expected to intersect two veins within a few weeks. Some good ore is being opened at a short distance from the portal of the adit. C. M. Root is superintendent.—At the Pacific, Wingfield & Nixon, of Goldfield, have 10 men at work driving the adit and running a drift from the adit to intersect the old channel under Fillmore ridge.—Several discoveries have been made on numerous small properties near Gibsonville in the past week.—The Sixteen-to-One and Bonanza King mines remain idle, and there is little promise of an early settlement of the litigation.—The Rainbow mill is running on good ore. The main vein is about 30 in. of rich ore.—The Twenty-One vein is 10 in. wide, and considerable high-grade ore is being sacked.—Kellar and associates are developing a promising claim near Bowman's Dam.

Alleghany, September 1.

The Eclipse Mining Co. has driven a 140-ft. adit on its property near Gibsonville, and expects to cut the vein in a short distance. Surface work has opened a vein the length of the claims, and the company has ordered a 10-stamp mill for the property, which is held under a \$10,000 bond.

TRINITY COUNTY.

Wilson & Ehrmann have opened the ore-shoot in their lease at the Gifford mine, in Eastman gulch, for a distance of 50 ft., and have 25 tons of ore on the dump that will assay between \$300 and \$500 per ton.

TUOLUMNE COUNTY.

Charles H. Sergerstrom, of Sonora, has secured a bond on the Dutch mine, at Quartz, and is re-opening the property. A crew of men has been started repairing the 20-stamp mill and cleaning out the shaft. The mine has been under the management of the Dutch Mining Co. for the past 15 years, and has a record of producing \$2,000,000.—The O'Hara mine at Brown's Flat, has been bonded to T. C. Crawford, of London, for \$50,000. The agreement provides that the bonders commence active work the first of this month and expend at least \$1000 per month in development. J. F. O'Hara will have charge of the work.—George A. Richards has instituted suit against C. R. Watson, C. A. Fitzgerald, and John Doe Dunkinson, to recover an undivided one-third interest in the Alameda mine.—The Mack mill has been started on a 200-ton lot of ore from the Harper Brothers' mine.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—The Kennedy Gold Mining Co., operating the Centennial mine on Leavenworth mountain, is preparing to build a 50-ton stamp mill. The ore is worth from \$12 to \$14 per ton, in gold, silver, and copper. David Kennedy is manager.—A rich discovery has just been made at the Seven-Thirty mine, on Sherman mountain by W. P. Alkire & Co., who have opened a body of smelting ore that is from 8 to 12 in. wide. Assays run from 650 to 700 oz. silver per ton.—J. Bowen started operations this week on a group of claims in East Argentine. The adit is being cleaned out and retimbered preparatory to stoping on a streak of ore that is from 8 to 10 in. wide, and assays from 120 to 130 oz. silver per ton.—Shipments of smelting ore have been started from the Drummond mine, situated on Columbian mountain. During the last week a streak of smelting ore was exposed in the east drift that is from 18 in. to 2 ft. wide, and samples taken across the same, show average content of \$46 per ton silver and lead.—A new discovery is just reported from the Aetna vein of the Capital Mining & Milling Co. In extending the east drift a streak of smelting ore has been cut that is from 10 to 14 in. wide, and assays 18 oz. gold, 35 oz. silver, and 9% in copper. W. M. Cooper is manager.—The Highlander mine, situated in Virginia canyon, is being re-opened. The adit has been cleaned out and a drift started upon an 8-in. streak of ore that is worth from \$20 to \$22 per ton in gold.—The bond of \$6000 held by the Gold Quartz Mining Co. on the Klondyke group of claims at Alice, was lifted last week by W. A. Maxwell, the manager.—The Mineral Chief mine on Democrat mountain, owned by the Linn Con. Mining & Milling Co., has been placed upon a self-supporting basis and a net earning of \$3000 per month is being made. Of this sum \$1000 is being used each month to lift outstanding bonds, while the balance is being placed in the development fund. C. E. Pughe is manager.—O. Shaffer & Co., leasing on the 11th level of the Old Town, have one of the best paying propositions in the district. In ten days two men extracted \$2000 worth of ore. Georgetown, August 30.

DENVER COUNTY.

The Modern Smelting & Refining Co. is buying ore in Clear Creek and Gilpin counties for their plant at Utah Junction near Denver.

GILPIN COUNTY.

(Special Correspondence).—A contract has been let for building the D. N. W. & P. branch from the main line to Central City. This will be the first standard-gauge line into Gilpin county, and will afford competition in transportation. While a few miles longer than the present route by way of the C. & S., the new line has an advantage in grades and curvetures.—The Kansas vein has been cut in the Newhouse tunnel and shows some lead and iron sulphide with small amounts of gold and silver. The tunnel-head has recently been driven through the veins of the 'patch' near Nevadaville.

Central City, August 31.

LAKE COUNTY.

William S. Jones, operating the Robert E. Lee mine, on a lease, is arranging to ship the ore, which runs 25% zinc, to the smelter.

OURAY COUNTY.

The Mono Baltic Mining & Smelting Co. have purchased the machinery for its new plant at Ironton, and will commence grading shortly.—Operations have been resumed at the property of the Copper Gulch Mining Co. E. S. De Golyer is manager.

SAN JUAN COUNTY.

The Iowa-Tiger Leasing Co., of Silverton, paid its fourth dividend of 20%.—The mill of the Silverton Mining Co. has been started but was shut down temporarily owing to a shortage of cars. A large amount of ore has been blocked out in the mine and as soon as regular shipments can be started the stamps will be dropping again.—There are 30 of the 100 new stamps dropping in the new mill of the Gold Prince at Animas Forks.

SUMMIT COUNTY.

At the International mine, near Robinson, work has been started on the vein that was opened two years ago, and it is understood that the company is blocking out a large amount of good milling ore.—Ault & Wiborg are to start work at the Frisco mill on ore from the Excelsior mine.—A good body of ore has been opened in the property of the Bledsoe Mining Co., in the Kokomo district. The vein is 2 ft. wide, and is all shipping ore. H. Pomeroy is in charge of the work.—At the Gold Bird mine the 300-ft. adit opened a 12-ft. vein that assays 52% lead with some silver and gold. The property is owned by George Pomeroy and Frank Brown, of Leadville.—Franklin Luty is shipping good ore from the Mayflower mine which he is operating under lease.—William Lindsay is shipping ore from his lease on the Wintergreen mine. The ore is a heavy iron sulphide with a good gold content.—Louis Johnston has secured a lease on the Iron Mask mine and is now erecting a plant on the property.—The Union Consolidated, on Gold hill, is being re-opened.

Operations are to be resumed at the Birds Nest group.—The Reconstruction group on Copper mountain, has been leased to Peter W. Breene, who has a force of men at work cleaning out the old workings.—On the River-side group a 2-ft. vein of lead-copper ore has been opened.

TELLER COUNTY.

The cross-cut on the 200-ft. level of the Mountain Beauty mine, on Bull hill, opened a shoot of \$100 ore. This portion of the mine is under lease to Moore & Bower, of Victor.—Wilson & Hoy shipped 6 tons of ore from the dump of the Gold Coin mine to the Cripple Creek mills and received \$25 per ton in settlement. The lessees have a second shipment of 25 tons ready and this is to be forwarded to the Standard mill at Colorado City.—The August output of the Whitney & McMullen lease on the Vindicator approximated 100 tons.—In the Pride of Cripple Creek mine a shoot of rich ore has been opened on the 630-ft. level. The vein is from 10 to 12 ft. wide, and assays \$30 per ton.—A new 10-drill Franklin compressor has been set up at the Doctor-Jack Pot claim on Raven hill, and is now supplying the lessees with power.—In the quarterly report of the Gold Dollar Consolidated Mining Co., H. L. Sheperd, the manager, states that the company has \$9500 on hand after paying dividends and all outstanding obligations.—The Rexal Gold Mining Co. opened a 5-ft. vein on the 700-ft. level by a 150-ft. cross-cut from the shaft. Samples assay from \$40 to \$250 per ton. R. H. Brooks is superintendent.—The Jennie V. Leasing Co. has resumed operations on the Monte Cristo property.

IDAHO.

IDAHO COUNTY.

At the Blue Ribbon property, five miles east of Elk City, a 7-ft. vein was intersected by an open-cut near the portal of the main adit. There is over 1000 ft. of development work on the property.—A rich shoot of ore was opened recently by the drift at the Buckhorn mine in the Ten Mile district. The drift has been run 250 ft. on the vein and cross-cuts driven every 25 ft. showing the vein to have an average width of 20 feet.—On the Gilt Edge property a 30-ft. vein has been opened 6 ft. of which is good milling ore. A. D. Bennett and J. Grinde, the owners, expect the lower adit to cut the vein in a short time.—A cross-cut has just been completed at the Gold Bug mine and another contract let. The vein has been opened on the surface for 1200 ft., and samples taken from open-cuts assayed from \$4 to \$200 gold per ton.—Nathan Hass has bonded the Houston property on Santiam creek.

OWYHEE COUNTY.

On the dump of the Big Four group on Boulder creek, the owners of the claims have 100 tons of \$13 ore, and are blocking out a large amount of similar ore in the mine. On a test run the concentrate from this ore assayed \$456 per ton.—At the Bushranger group four adits have cross-cut the ore showing it to have an average value of \$20 per ton. There are 25 tons of ore on the dump for a milling test.—Several rich stringers of ore have been cut by the

mill-level adit on the Banner property.—The Silver City Mining & Milling Co., near Silver City, is installing electric plant at its mine and active work will be resumed in a few days.

ILLINOIS.

MARION COUNTY.

(Special Correspondence).—A new oilfield has been discovered near Sandoval, in the south-central part of the State. Three gas wells have been brought in and two oil wells, which average 100 bbl. each. Leases have gone to a premium.

Sandoval, August 25.

KANSAS.

CHEROKEE COUNTY.

(Special Correspondence).—Several mills are under construction in the Empire district where ore is being opened at a depth of 150 ft.—Capp & Hinkman are re-opening some old workings on the Kennedy ground and taking out 15% ore from the 30-ft. level.—Cook & Stone are re-opening the Black Hill lease at Galena. A large pumping plant has been installed and the owners are planning the erection of a large mill.—The Ihlsing Mining Co. is erecting a mill on the Ping and Robertson leases and is to sink a 5 by 15-ft. shaft 325 ft. This will be the deepest shaft in camp as no ore is new being mined below the 265-ft. level.

Galena, August 31.

MICHIGAN.

The Michigan Copper Mining Co. has just finished the third diamond-drill hole on its present series, which is exploring south of the Evergreen-Knowlton lodes, in the strike of the three new Adventure lodes, and the drill is now being rigged up for the fourth hole. This will be put down along the same strike, some distance west of the others.—The Challenge exploration of the St. Mary's Mineral Land Co. has discontinued all operations. This work has been in progress for several years. A shaft was sunk to a depth of 850 ft. and extensive cross-cutting, driving, and diamond-drilling carried on from several levels. The eastern or Jacobsville sandstone was drilled into for a considerable distance by diamond-drill, so that its identification was positive, and from there westward a thorough cross section of the geology was made for a distance of over 3000 ft., while several of the more promising amygdaloid beds were opened and the one identified as the Baltic lode was diamond-drilled on the incline of the formation to great depth, but nothing that offered encouragement for further investigation was discovered. The Challenge shaft is two miles south of the Globe shaft which was abandoned a few months ago, and three miles south of the Champion mine.—The Hancock Consolidated Mining Co. has levied an assessment of \$2 per share, payable one-half On October 10 of this year, and one-half in February next year. The management has started a survey for a railway to the property and is considering the preliminaries of the railway as well as a mill. The showing underground has been much better than was anticipated, although the work is being done on a lode which was not known to exist at that time.

MISSOURI.

NEWTON COUNTY.

(Special Correspondence).—The Hancock Mining Co. has opened a good prospect at a depth of 140 ft. where the ore is 7 ft. thick, and runs 10% zinc.—After a series of accidents the Shoal Creek Mining Co. is again producing a large amount of silicate ore which is being cleaned on hand-jigs.—Bankard & Scott have opened 44 ft. of rich ore in the southern part of the Spring City camp, samples from which assay as high as 50% zinc. A mill is to be constructed on the property.

Spring City, August 30.

NEVADA.

CLARK COUNTY.

The Memphis Mining & Milling Co. has secured the Weeks ground, near Searchlight, and is installing a power plant preparatory to sinking. A. L. Hill is manager.—

The Fraction shaft, on the Homestead property, is to be sunk from the 600 to the 1000-ft. level. A compressor and power drills have been ordered and will be shipped to the mine shortly. The mill has been shut down till the shaft is completed.—The Copper Prince mine, near Nelson, was purchased by William Hambly for a group of Colorado capitalists for \$10,000; \$3000 was paid on the first installment, the balance to be paid within 90 days. Picked samples from the vein assayed 26% copper, 15 oz. silver, and \$20 gold per ton.—The Philadelphia-Searchlight Mining Co. has purchased a diamond-drill and will explore its property from the 600-ft. level. The vein at this level is broken and full of wall-rock, and the company hopes to cut the vein at some more solid point.

ELKO COUNTY.

The United States Mining & Smelting Co. has purchased the Ivy Wilson group of claims at Contact and will commence operations at an early date.

ESMERALDA COUNTY.

(Special Correspondence).—An increase of over 300% in the amount of bullion tax paid during the second quarter of the current year over the corresponding period in 1908, bears witness to the increased activity in mining throughout Nevada and the most conspicuous showing is made by Esmeralda county, and Goldfield, particularly, which paid over \$50,000, of which the Consolidated company paid \$40,000. The quarterly report of the State bullion tax agent calls attention to the efforts of the Pittsburgh Silver Peak company in this county and the Bamberger-Delamar company, of Lincoln county, to evade the payment of proper bullion taxes by means of statements at variance with those issued to the stockholders and declares that the litigation started against the former will be pressed to a final conclusion. It is shown that the Florence Goldfield company finally paid the disputed tax, amounting to over \$10,000.

The management of the Consolidated Mines Co. has decided to stope the Combination and Red Top veins from the present workings to the surface involving the opening of gigantic 'glory holes' on both veins. Ore is being stoped on the Combination No. 2, on ground adjoining the old Reilly lease, one of the early bonanzas of the district, and from this point the workings are in good ore all the way to the Combination main shaft, a distance of 700 ft. From the surface a series of shafts will be sunk through the hanging wall into this vein and wall-matter broken for use in back-filling. Between the apex of the vein and the railroad track a large crusher will be installed and the crushed ore carried by a belt conveyor to the cars for transportation to the mills. The Red Top vein has been penetrated by the east cross-cut at the 330-ft. level, while a steady production is being made from the vein at the 260-ft. level. Within a short time the north drift from the Clemont shaft will reach this vein on the Lucky Boy claim at a depth of 600 ft., near the point where the vein turns to the west, and below the point where the largest stopes are opened at the 260-ft. level. The ore of this vein is rich and is mixed with lower grade material in milling. Shipments of high-grade ore from the Hampton stope and the rich orebody exposed at the 403-ft. level of the Mohawk, have been resumed and 4 carloads have been sent to the smelter which sampled from \$600 to \$1200 per ton.—An adit is now being driven into the hill at the southern end of the Jumbo claim to tap the veins which yielded exceedingly rich ore to lessees several years ago, the first objective point being the old workings of the Zinn lease. The management announces that during the coming autumn, probably in November, underground surveys will be completed upon which to base an appraisalment of the company's ore reserves. The mines of the Consolidated company now have over 35 miles of workings, with ore exposed in many points, and the available tonnage has been vastly augmented during the past six months. A winze has been sunk 50 ft. from the sill floors at the 600-ft. level of the Mohawk and a drift from the bottom of this winze is being driven in good ore. The pump and electric installation are completed at the 1000-ft. level of the Cler-

mont shaft whence a cross-cut has been started toward the Mohawk vein. Low-grade ore has been found at the 860-ft. level, but the vein is still some distance away, and at the 730-ft. level the orebody is proving of excellent proportions and is being rapidly developed.

Goldfield, August 31.

LYON COUNTY.

On the 500-ft. level of the Mason Valley mine a cross-cut opened a body of high-grade ore. The cross-cut was started to intersect the ore found on the 400-ft. where it averaged 3% copper. The grade on the 500 was higher, however, as the ore contains a large amount of bornite. A blind lead of native copper was also opened which the company will sink on. There is considerable talk of the Mason Valley and Bluestone mines consolidating this month.

NYE COUNTY.

(Special Correspondence).—The winze from the 1050-ft. level of the Belmont has reached a point below the 1100-ft. level, and has cut several stringers of good-grade ore. A 5-ft. vein has also been opened that is estimated to run about \$30 per ton. S. H. Brady is superintendent.—The Mizpah shaft, at the Tonopah, has reached the 1500-ft. level and a sump has cut 24 ft. below this point. A station will be cut and the territory between this point and the 600-ft. level thoroughly prospected.—A small vein of good ore has been struck in the hanging wall of the Triangle vein on the 390-ft. level of the Montana-Tonopah.—It is reported that the Bullfrog-Sioux company is arranging for the erection of a custom mill at Pioneer.—The Herring lease on Jim Butler has struck a shoot of ore running \$20 to \$100 per ton.

Tonopah, August 31.

WHITE PINE COUNTY.

Thomas H. Cole, of Duluth, has secured an option on 229,175 shares of the Butte-Ely treasury stock at \$1 per share.—The Ely Central has commenced work on its property east of Copper Flat and will sink the shaft to the 550-ft. level.—The drills of the Nevada Consolidated company are working near the Liberty line and the ground there is being proved excellent for steam shovel mining.—The road from the Success mine to the McGill smelter has been repaired and a contract let to haul the ore from the mine to the smelter, 23 miles.

OREGON.

JOSEPHINE COUNTY.

The United Copper-Gold Mining Co., of Salem, has completed the wagon road from Booth Ferry to its holdings on Pickett creek, 14 miles from Grants Pass, and is hauling in machinery for its plant. The company has a compressor, machine drills, and power plant, and is planning a large amount of development work. A contract has been let to a Portland firm to erect a 50-ton smelter and if it proves successful, a larger plant will be erected. O. A. Thomas is manager.

UTAH.

JUAB COUNTY.

The east cross-cut from the 225-ft. level of the East Tin-tic Development Co.'s property opened a 15-ft. vein of ore. The company will sink the shaft to the 500-ft. point.—A contract has been let to sink the shaft of the Swansea Consolidated company 200 ft. This will make the shaft 1065 ft. deep.

TOOELE COUNTY.

The fifth building of the International Smelting & Refining Co., at Pine canyon, has been started. The steel-work for the power plant is completed and the brick-work under way. The structural steel for the roaster building is on the ground and the foundations nearly complete.

WASHINGTON.

STEVENS COUNTY.

(Special Correspondence).—It will require three weeks to drain the Old Bonanza mine, near Bossburg, when 30 men will be employed.—The aerial tram at the First Thought

mine is being put in shape to handle an increased output. It is reported that 100 men will be employed in this mine by October 1.—Good looking vein material has been cut by the Blue Grass adit, on Toulon mountain.—The Border Mining & Milling Co. has purchased a water-right on Boulder creek to generate 3000 hp.—The Northport Smelting & Refining Co. has had a survey made, to define its property, from the Northport town-site, and it is reported will extend its yards and erect new buildings.—The Oriole Mining Co., in Metaline district, is inviting bids for the installation of an air-compressor and machine-drills. A concentrator will probably be installed for handling low-grade ore.—Machinery is to be installed at the Tungsten King mine. A bid has been received by the company from France for the entire output of the mine and concentrator, which is expected to amount to about \$15,000 per month.

Colville, August 24.

CANADA.

BRITISH COLUMBIA.

(Special Correspondence).—The Nickel Plate mine, at Hedley, has been taken over by the Exploration Syndicate, of New York, made up of M. K. Rodgers, of Seattle, and numerous stockholders of the United States Steel Corporation; the price was in the neighborhood of \$1,000,000. T. Walter Beam, a representative of the syndicate, is temporarily in charge of the property. It is not yet announced who will be the active manager for the company, though it is certain that Mr. Rodgers will be influential, as he is one of the heaviest individual stockholders. The property was, prior to this purchase, in control of the Daly estate. It is announced that some extensive development will be done.

Hedley, August 26.

On Whipsaw creek, a tributary of the Similkameen river, a 22-ft. vein of lead-silver ore has been discovered. Three claims have been staked by Knight and Day, and a number of open-cuts run through the vein. The average of a number of samples assayed 60% lead, 26 oz. silver, and \$1.60 gold per ton.—The British Columbia Copper Co. has secured an interest in the New Dominion Copper Co., and it is understood that the two companies will be consolidated the ore going through the British Columbia company's smelter. This company has also secured a bond on the Sapho group, near Midway. A large amount of development work has been done on the property, and a good tonnage of copper ore blocked out.—The Athabasca mine, near Nelson, has been purchased by a new company and will be re-opened.—J. S. Airheart has bonded the United mine near Ainsworth, and will concentrate the ore at the Highland plant.—A 7-ft. vein has been opened on the Black Hawk, Red Hawk, and Night Hawk claims on the Salmon river. The ore is similar to that coming from the Nickel Plate mine.—O. L. Knight & Co. have secured a contract for a large amount of diamond-drilling in the Le Roi mine. This work is expected to keep three machines running for the next six months.—Considerable surface work is being done at the Hattie Brown group, recently acquired by the Fife Mines, Ltd., and it is reported that the company is to prospect the ground with diamond-drills. Charles Dempster is manager.—The tramway at the Vancouver mine, near Silverton, is being repaired and the mill will be running at its full capacity in a short time.

ONTARIO.

The shaft of the Cobalt Townsite Mining Co. has been unwatered and operations resumed at that mine. Considerable lateral work has been done on the 110-ft. level, and some ore shipped.—The surface work on the Nipissing has opened two more veins on that property, making the total 130. Both are decomposed with large amounts of argentite, assaying from 4000 to 5000 oz. of silver per ton. Number 130 is 4 in. wide and has been stripped for a distance of 60 ft., while number 129 is 2 in. wide, and is only opened for a few feet.—The diamond-drill on the Alexander property has cut the slate at a depth of 250 ft., and the shaft will be sunk to that point. The shaft is now down 160 ft. and the drill-core indicates that a 2-in. vein is within 65 ft. of the point the company proposes to sink

to.—A cross-cut from the 190-ft. level of the Cobalt Lake mine opened a 2-in. vein when in 90 ft. A drift is being run on the vein and the ore sacked.—The Jacobs Exploration company opened a 20-in. vein on the 170-ft. level of the North Cobalt property.—Page and Pickens, the crack Arizona drill team, easily won the drilling contest at Cobalt, distancing the nearest competitors by 13 in.—The cross-cut from the 60-ft. level of the Nancy Helen opened a 6-in. vein with a 3-in. streak assaying 6000 oz. of silver. Two 1-in. veins were also cut.—A complete electric-driven compressor plant has been ordered for the Bailey mine and the company has started grading for its installation.

QUEBEC.

The Spalding iron mine has been bonded for \$500,000 with the understanding that the holders of the option expend \$50,000 in development work on the property.—The Eustis mine, near Sherbrooke, is shipping 1500 tons per month of ore that runs about 45% sulphur, to chemical firms in Boston. The residue is shipped to the Eustis smelter at Norfolk, Virginia.

MEXICO.

CAMPECHE.

A valuable deposit of whiting (chalk), estimated to contain over 3,000,000 tons, has been discovered close to the banks of the Chamton river, State of Campeche, and will be actively developed by the International Whiting & Fibre Co., of Mobile. W. H. Bell, of Vicksburg, Mississippi, is president of the company, and J. T. Burk is vice-president.

CHIAPAS.

The Pan-American railroad reaches to a point about 40 miles south of Tapachula, close to the Guatemalan frontier, and the gap from this point to the nearest Guatemalan railroad (the Champerico and Ocos lines) is only about 40 kilometres. Pending the completion of the line an effort is being made to establish a mail service.

CHIHUAHUA.

Over 3000 tons of 70-lb. steel rails have been ordered to replace the 45-lb. rails on the Sierra Madre & Pacific railroad, thus showing the determination on the part of the Pearson interests to bring these lines up to modern standards.

GUERRERO.

The discovery of high-grade amethysts on ground that also yields gold and silver is of interest. The gems are said to be of fine quality. The owner of the claims that contain these is Plácido García, and the claims are at Taxco.

HIDALGO.

A bad fire occurred on August 10 in the lower levels of the El Paraíso mine at Pachuca. Three native miners are known to have lost their lives, eight are still missing, and several were injured. The fire has been extinguished, but it is still impossible to get to the lower levels owing to the dangerous condition of the works where the timbers are burnt out.

JALISCO.

The Southern Pacific has commenced construction from Tequila, Jalisco, northward and will soon tap the mining district of Hostotipaquillo. The roadbed is completed 20 miles up to Quemada, and it is expected that the line will be in operation by October 1.

It is reported that the properties of the Quien Sabe Mining Co., near Guadalajara, are to be re-opened shortly. There is a modern reduction plant on the property and considerable ore blocked out in the mine. Patrick Blalack owns the controlling interest in the company.—The new plant of the Tajo Mining Co., operating in the San Sebastián district, is handling 30 tons of ore per day. Robert H. Lilly is manager.

MEXICO.

The Cia. Manufacturera del Hormo Partridge, S. A., is erecting an experimental plant in the City of Mexico. It is reported that the company has secured London backing to erect a larger plant at Manzanillo. Allen R. Partridge is the inventor of the furnace and the moving spirit in the company.

Special Correspondence.

DENVER, COLORADO.

Smelter Situation. — Chlorination at Georgetown. — Cyanidation at Central City. — Land Frauds and Taxes on Coal Lands. — Geological Survey.

The smelting situation at Denver is becoming interesting. In recent years there has been a marked decrease in the amount of ore treated here. The bulk of the Cripple Creek ore now goes to the mills rather than to the smelters and neither new camps nor new discoveries in old mines have come forward to take its place. The smelters say the shortage is natural. The miners complain of high smelting rates. To meet the situation there is much talk of new smelters and mills. The Carpenter smelter, at Golden, has been purchased by the newly organized North American Smelter Mines Co., and is being prepared for a run. A Vivian reverberatory furnace, designed by Geo. G. Vivian, recently of the Knight smelter, at Tintic, Utah, is to be built, electric power will be installed, and in all, some \$25,000 is to be spent in improvements. The smelter was built nearly 10 years ago by F. R. Carpenter for Berry Bros., of Detroit, and is designed especially to treat the pyritic and dry ores of Gilpin and Clear Creek counties. When it was running before, a \$3 smelting rate was established, and there was a great ransacking of old stopes through the two counties. The Saratoga mine, owned by Berry Bros., however, furnished much of the ore. It is doubtful how much ore would be brought out by a re-establishment of the old rate. The large producers are known to be under contract to the A. S. & R. Co., and the latter will undoubtedly fight to retain as much as possible of the free ore. Fortunately the Riedel Investment Co., which is backing the North American company, can rely on considerable production from mines which it controls, along the Rochford tunnel on Donaldson mountain. Work here is to be pushed rapidly, and \$50,000 is to be spent on development with Frank H. Nye, formerly State Mine Inspector, superintending, and J. H. Robeson as consulting engineer. It may be safely predicted that considerable ore will be found but whether enough to supply the smelter is less certain. There is the more doubt as to the outcome since the Modern smelter at Utah Junction is already in the market, and is stocking up preparatory to going into blast. This is a small but complete plant which must necessarily rely largely on Gilpin and Clear Creek counties for ore. The North American has bought the Kilton sampler at Idaho Springs, and presumably will buy or lease a plant at Central City. The Modern, on the other hand, proposes to sample at the smelter, and to give the miner some benefit from the decrease in cost. There are naturally all sorts of rumors as to impending cuts in rates, but nothing has yet been officially announced. To add to the interest in the situation, construction is already under way at Georgetown on a new mill in which the Malm dry chlorination process is to be applied, and plans are well matured at Central City for a 300-ton cyanide mill to do custom work. The attempt to cyanide Gilpin county ores will be watched with interest, as previous efforts in this direction have not succeeded. Marshall R. Draper and Percy Alsdorf refused to be scared, and the present enterprise is founded on the results of nearly a year's work in one portion of the mill of the Fifty Gold Mines Corporation. That they are not to be alone in the work is indicated by the announcement that Henry P. Lowe, who now has the Topeka, Frontenac, and Adduddell mines, is preparing to erect a 10-ton experimental cyanide plant at the Frontenac or Iron City mill.

The Rocky Mountain smelter at Florence, built seven years ago by some enthusiastic Iowa capitalists to treat Cripple Creek ores by the pyritic process, is to be sold, September 24, to satisfy a judgment in favor of the Iowa Fiduciary Co. for \$78,130. The plant originally cost \$250,000. It ran for a short time only. About two years ago the Colorado Smelting & Refining Co., with which was asso-

ciated the Troy Consolidated Mines Co., took over the property, and prepared to put it in operation. Evidently the managers thought better of it later, as nothing was done, and it still stands idle.

Coal-land frauds are again to the fore. The Government has just brought suits in equity to recover lands and damages for coal extracted, both in Rout county and near Walsenburg. A number of well known Colorado men are involved. It is charged that the land was illegally entered. The Black Hills Land & Cattle Co., and the Yampa Fuel & Iron Co., are the concerns involved. At the same time the assessor in Huerfano county is in trouble, and about to be removed by the Governor for assessing as grazing land the reserve lands held by the coal companies. He has, following what has heretofore been the custom, assessed as coal-land only that from which coal is actually being produced. As to the equitable method of assessing unmined mineral there is room for much difference of opinion, and the case will be watched with much interest by the big coal companies. If all their reserve lands be taxed on their coal value there will be a big difference in the revenue of the State—and in the profits from coal mining.

The geological survey of the Breckenridge district is nearly complete. E. S. Bastin, who has been assisting F. L. Ransome in the work, will leave September 6 to take up detailed work at Idaho Springs, following the work done there a few years ago by J. E. Spurr and George H. Garrey. Mr. Bastin will extend the surveys to the north to include Central City and adjacent districts.

LONDON.

Carn Brea & Tincroft. — Low Fuel Costs. — Conditions in Cornwall.

During the last year I have referred more than once to the increasing output of one of the old Cornish tin mines, the Carn Brea & Tincroft. The figures for the first half of the current year further confirm the impression previously given that increased efficiency is being carefully studied. With practically no additional plant the amount of ore treated during the six months was 36,825 tons, as compared with 34,790 tons, 31,828 tons, and 29,677 tons during the preceding half years. The tin concentrate sold was 567 tons as compared with 518 tons, 457 tons, and 396 tons. That the increased output has not been at the expense of the quality of the ore may be seen from the fact that the average produce during the half year was 34.55 lb. of concentrate per ton of ore, as compared with 33.40 lb., 32.2 lb., and 29.91 lb. The average price obtained for the concentrate was £69, as compared with £68, £73, and £87, and the amount realized was £39,428, as compared with £35,518, £33,845, and £34,649. From these figures it is clear that in spite of the low price of tin the mine has enjoyed a larger income from a higher production of ore and concentrate. In fact in 1906, when prices were so high the half yearly income was not as great as at present. In addition to the tin concentrate, small amounts of arsenic, copper, and tungsten ores were produced and sold, so that the total income was £42,846. The costs work out at £39,746, and the lord's dues £1550, leaving a net profit of £1550. The development and exploration work at Carn Brea & Tincroft are being carried out with vigor. At six different points rock-drills are being used in development, and at eight hand labor is employed. The general safety of the workings is being attended to more carefully than formerly, an improvement in policy rendered necessary by several recent accidents. Timbers are being renewed, and at several points concrete has been used in strengthening weak points in shafts. The engineers have had a good deal to say recently with regard to their economies in the fuel consumption at the steam plant. They are in keen rivalry with the other mines, such as South Crofty, where electric power is used. The figures for coal consumption for the half year are 1737 tons. It is calculated that the cost of hoisting the ore to the surface, including the hoisting of men and supplies, comes out at just over 3½d. per ton of ore. It will be noticed that in spite of the improvements in production, the margin of profit is small. The company oscillates pretty regularly between profits and

losses, and share-holders seldom get anything. This state of things is typical of most of the Cornish mines nowadays. The share-holders are chiefly people who have a stake in the county in other ways, either as landowners, merchants, or tradesmen. To them the further impoverishment of Cornwall, consequent on the closing of a mine is a more serious thing than the absence of dividends.

About a year ago it was mentioned in these columns that the directors of the company had for a long time been thinking of raising new capital and bringing the workings and machinery up to date. Whether or not this will be eventually effected remains to be seen, but in the meantime the efforts to more fully utilize the present resources have been suitably rewarded.

NOME, ALASKA.

Artificial Freezing of Flooded Mines.—Rosene Concession in Siberia.
—Big Nuggets from Kuskokwim.—Russian Restrictions in Siberia

A new era in the development of placer-mining, which has thus far proved successful, has aroused the lethargy of third-beach operators. A big syndicate, heavily capitalized, will continue the ammonia-freezing process in all the recent flooded claims, and the work is now thoroughly under way. Late in June a terrific geyser broke from the shaft of the Bessie mine, sending a column of water 70 ft. into the air. This flood subsided only when nearly all the contiguous claims were drowned out, the operators and miners barely escaping with their lives.

Freezing by means of forced ventilation in winter has been in vogue in Alaska for years, hence it is but a step from this method to the new scheme of artificial freezing recently adopted by the operators of the Cyrus Noble claim for accelerating summer work. In eight days, at an expense of \$1000, the lower drifts of this mine were effectually frozen and a continuous flow of 6 to 10 miner's inches of water stopped, so that mining could be resumed. The plant was installed by an engineer of the Nome Cold Storage Meat Co., and is proving so successful that similar efforts will be made by other operators of the adjacent flooded properties, comprising the heaviest gold producers of the Nome district, namely, the Bessie, Saturday No. 2, Nettie, Mable, Cyrus Noble, and the Portland bench, and other Little creek mines of the Pioneer company. The lessees and owners of nearly all the claims in the flooded district have combined, and the construction of a two-mile drainage tunnel to the sea will begin at once, to prevent a recurrence of disaster should the steam-points at any time again penetrate the subterranean flow which for years has blocked development and production.

Several big gold nuggets, the largest of which weighs 29 oz., were brought down from the Innoko regions by A. Pelky, a recent arrival. Each shows a sprinkling of ochre-colored quartz, resembling the cinnabar ore which is so profuse in the upper tributaries of the Kuskokwim. There were seven of these in all, weighing respectively 29, 15¼, 12, 10½, 6, 5¼, and 3½ oz. A big poke of coarse gold was also exhibited with these in the windows of a Nome jeweler. For days crowds thronged the place to get a glimpse of the treasure. The assay value of the gold comprising the nuggets was computed at \$19.75 per oz. It is needless to say that the Kuskokwim stampede has started afresh.

With the opening of navigation came reports confirming the withdrawal of Jafet Lindeberg and the other American stockholders in the mining concession known as the North East Siberian Mining & Trading Co. No supplies or laborers were sent to Anadyr from Nome this year by the president of the Pioneer company, and Siberia has been dubbed a 'dead one' by all Alaskan operators. Active work on the diggings prospected and worked last year, from which the product of over \$10,000 was fished by the Russian governor by the aid of a gunboat, however, has been resumed by the Russian stockholders, who have bought out the American interests. Added to this, Governor Kalikikoff has promulgated an imperial edict from the Czar to the effect that all trading of craft from Nome or elsewhere must stop inside the concession limits, namely, Cape Alexander to Cape Serdge, in the Arctic ocean, under penalty of confiscation.

The whole fleet of ivory, fur, and whalebone traders is accordingly scattered in consternation, trying to avoid the gunboat patrol already installed on the Siberian coast. Nome is, in consequence of recent stampedes, utilizing many of the 'mosquito fleet' in furnishing supplies and transportation to the Kuskokwim and upper river mining regions tributary to the Yukon river. Nome in a business sense is very dull, while mining is also backward, owing to the dry season and dearth of water. Upward of forty business houses in the city will close this fall, but an era of increased activity in dredging and big capitalized projects is promised in the near future that will materially increase placer products of Seward Peninsula.

KALGOORLIE, WESTERN AUSTRALIA.

Golden Horseshoe.—New Plant.—Monthly Output.—Australasian Institute of Mining Engineers.

Excepting a good strike in the Golden Horseshoe at 1700 ft. and a few small finds in other mines, there is little to note for the month. It may be mentioned that work in the deep winze from level 14 in the Great Fingall is showing better ore than formerly, and it is to be hoped that such will continue. Many years ago this mine was abandoned, as nothing was found payable below the third level; but on being re-opened a great quantity of good ore was worked, keeping 100 stamps busy for several years and many dividends were paid. A poor zone was entered about the fourteenth level, and now only about 50 stamps are operating. A vacuum slime-plant is at work on this mine. At the Perseverance main shaft it is proposed to install skips from the 1900-ft. level. An ore-bin will be cut out at this level, and it is also proposed to erect a hoist here, and haul from lower levels to this point. This is the only instance of stage-winding on this field, and results will be watched carefully. A trial is to be made with the vacuum process on the roasted ore at the Perseverance. This is interesting, as this mill has a large press plant of 12 five-ton capacity presses, and a former management had a trial of the Moore process, but results were never published. There seems to be a feeling among many here that the vacuum process will not be a success on fresh slime for either the wet or dry crushing mills; anyhow, there is no rush to install vacuum plants in the big mills.

The second A. E. G. turbo-generator of 500 kw. is now running on the Horseshoe. These generate power for motors all over the surface, and are giving great satisfaction. As the tonnage is now approaching 25,000 tons per month, 15 new Wilfley tables are being installed to deal with the tubemill product; and pumps are being erected to pump the concentrate instead of trucking from the tables. For some time past the Government Water Supply Department has been troubled by rapid decay of the cast-iron water-mains in Kalgoorlie and Boulder City, and attribute this to leakage of current from the electric tramway system. In order to test whether electrolysis is going on or not, 22 small meters have been set up in the 20½ miles of tramways, at regular intervals, and connected with the rails. The test has just started, and will be watched closely.

During June the principal mines returned as follows:

| Name. | Tonnage. | Value. | Profit. |
|------------------------------|----------|-----------|----------|
| Associated | 11,284 | \$100,000 | \$25,000 |
| Associated Northern Blocks.. | 3,750 | 32,000 | 12,000 |
| Golden Horseshoe | 24,013 | 255,000 | 100,000 |
| Golden Ridge | 2,188 | 28,000 | 14,000 |
| Great Boulder Proprietary... | 18,188 | 250,000 | 132,000 |
| Great Boulder Perseverance. | 18,262 | 135,000 | 17,000 |
| Great Fingall | 10,172 | 70,000 | 4,000 |
| Hainault | 5,180 | 34,000 | 4,800 |
| Ivanhoe | 18,962 | 200,000 | 100,000 |
| Kalgurli | 10,580 | 140,000 | 75,000 |
| Kalgurli South | 9,039 | 62,000 | 15,000 |
| Lake View Consols..... | 11,053 | 76,000 | 13,000 |
| Lancefield | 4,534 | 38,000 | |
| Oroya-Brownhill | 11,420 | 100,000 | 33,000 |
| Oroya-Black Range | 4,273 | 53,000 | 19,000 |
| Sons of Gwalia | 13,040 | 102,000 | 34,000 |
| Sons of Gwalia South..... | 1,900 | 22,000 | 4,500 |

Since the recent meeting of the Australasian Institute of Mining Engineers in this centre, the local members are about to form a branch, just as has been done in America with the Mining & Metallurgical Society. It is proposed to hold meetings once a month, and without doubt some interesting and valuable discussions will be forthcoming. The annual meetings are all very well, but in a country of such distances as in Australia, a large crowd seldom gets together; and with frequent meetings the Institute will become a live affair.

CHIHUAHUA, MEXICO.

Republica Mine.—Development in Cusihiuiriachic. — Dios te Guie.

The República mine, near Ocampo, in the Rayón district of Chihuahua, which, through inability to get fuel during the heavy rainy season, had to cease operations and was partly flooded, has again been able to contract for the wood needed for fuel, and the work of unwatering will soon be started. In the meantime the new manager, E. H. Webster, is re-treating some of the tailing in the mill, a part of the dump, and some surface ores, that the former management did not consider of high enough grade, so that the shipments of concentrate and bullion will undoubtedly be resumed early in October.

At Cusihiuiriachic the Promontorio, of the Cusi Mining Co., controlled by Potter Palmer, Jr., of Chicago, and under the management of M. F. Crosette, is opening up splendidly. This property was bought the first of this year, from Delgado & Barcenas, for \$115,000, and already shows more than double that value with very little development work, and it is looked upon as one of the nicest small purchases that has been made in Chihuahua for several years. The ore is highly silicious and taley, assaying several hundred ounces silver and about 2% copper. The copper, however, is finely disseminated through the ore as chalcopryite, but it is believed that the ore will lend itself readily to concentration after fine grinding, and thus cleaned of the copper the tailing may be cyanided; with this idea the company will make its experiments for the erection of a mill. Another mine that has developed into a wonderfully rich one, at a comparatively small purchase price (\$25,000) is the San Francisco of the Qualey Bros, in Yoquivo. It has been mentioned several times in these letters. New machinery has recently been erected and shipments will soon be resumed. Tests are being made in Denver on the ore with a view to planning for a mill. The Qualey Bros. have also just taken a lease and bond on the Dios te Guie mine in the Guerrero district, and it is understood that the developments would certainly indicate that God is guiding them, as the name prays, and that we will soon hear of another rich mine in western Chihuahua.

MEXICO.

New University.—Oil and Gas in Mexico.—Llanitos Mines. Durango.—

Railroad Extensions.—Buena Fe, Jalisco.—Coal Mining Activity.

—Mining Law.—El Tigre.

The sub-secretary of Public Instruction, Ezequiel A. Chávez, has just returned from California, where he was sent by the Mexican Government to study the higher educational methods of that State. He included in his tour the universities of Stanford and Berkeley. At the latter he was a guest for six weeks. Señor Chávez is preparing a report for the Ministry of Public Instruction. His visit was in relation to the National University, which is to be inaugurated on the centennial of the independence of Mexico on September 16, 1910. This will be the first modern institution of higher education in Mexico.

In view of the present political disturbances and of the pessimistic attitude of many foreigners toward the immediate future of Mexico, it is interesting to note that powerful capitalists still have confidence, as is evidenced by investments recently made. Contracts have been let for over \$1,000,000, and active construction work has been begun on the gas plant for Mexico City. Gas is to be manufactured from crude oil supplied from the Ebano oilfields. A large part

of the machinery has arrived at Tampico, and over 2000 tons of cast-iron pipe has been delivered at Mexico City. The plant to be erected will have a capacity of 1,000,000 cu. ft., and is designed on the same general lines as those at Los Angeles and San Francisco, California. The company owning the concession and erecting the plant is known as the Mexican National Gas Co. E. L. Doheny is president, and C. A. Campbell vice-president, both of Los Angeles; W. L. Mardinis is assistant secretary, and J. W. Warren general superintendent.

The Ebano oilfields are owned by the Doheny interests under the title of the Mexican Petroleum Co., and it is stated that the wells are producing heavily, and yet there is an unexplained shortage of fuel-oil on the National Railroads, which draw their supply from this source. The statement is credited to J. J. Waters, superintendent of motive power on the railroad, that unless there is an improvement in the oil situation, more coal-burning locomotives will be placed in commission. A pipe-line is to be constructed from what are known as the 'lower' fields of the Mexican Petroleum Co., near Tuxpán, Vera Cruz, to Tampico, a distance of over 100 miles, and a pipe line will be built to Mexico City.

W. E. Burk and H. W. Palmer, of Louisville, Kentucky, are now in Mexico City arranging for the immediate construction of a large portland cement plant, to have a capacity of 200,000 bbl. per year, and it is expected that the plant will be in full operation inside of one year. A great deal of machinery has already been purchased. The plant will be situated a short distance from Mexico City on the line of the Mexican Central. The papers have been signed which make the final consolidation of the hydro-electric and power interests in the State of Jalisco, to which we have already referred. The new company will be the Cia. Hidro-eléctrica é Irrigado de Chapala, S. A., which will absorb the Cia. Nueva de Tranvías Luz y Fuerza Eléctrica de Guadalajara. The capital of the new company, as finally arranged, will be \$12,000,000 in shares, with an issue of \$6,000,000 in bonds. E. Pinson will be manager.

The Sierra Madre Land & Lumber Co. has been absorbed by the F. S. Pearson interests for \$2,000,000, and this now adds something like 3,000,000 acres of lumber lands to the consolidation of interests held by Mr. Pearson in northern Mexico. Luis Riva is the legal representative of the Pearson interests in Mexico City, who carried through the transfer. Hiram C. Smith is the vice-president and general manager of the lumber department of the Mexican Northwestern Railroad Co. Interesting mining developments are going on in northwestern Durango. The Llanitos Consolidated Mines Co., owning mines in the mining camp of San José de Los Llanitos, is putting in a hydro-electric power-plant to supply power to run a number of diamond-drills, which are being used to push exploration and development, and block out as large a body of ore as possible with the least delay. For the last 20 years rich ore has been shipped from this camp on mule-back to Culiacán, where it was purchased by the ore-buyers. Large shipments have been made which ran as high as \$1 per pound of ore. The yield of some of the rich streaks has run as high as 32 oz. gold, and 1126 oz. silver per ton. Besides these, there are large bodies of low-grade ore. It is the intention of the company to erect a modern mill and cyanide plant. There are other important camps in this district. Close to the Llanitos is the San Andrés de la Sierra, which has produced more than \$13,000,000 in silver, and the La Portilla, which made a shipment of 20 donkey-loads of ore that produced \$40,000. Besides these are the well known mines of Velardeña, Penoles, Pedriceña, Ventanas, and Guanacevi. The extension of the Mexican International railroad beyond Tepehuanes will open up and assist to develop this valuable mineral region, and numerous properties now lying idle will re-open.

The announcement that a big mill, with a capacity of 1000 tons per day will be built by the Palmilla Mining Co. near Parral has had the effect of greatly stimulating mining in the district, and a hopeful spirit exists.

A few days ago the first through sleeper made the run between Mexico City and Salina Cruz. This new service will be a great boon to mining men who contemplate the trip to the Far South. He can now go through from the

United States to the Isthmus of Tehuantepec, and continue his trip by steamer on either ocean, and soon he will be able to travel still farther, as the missing link of railroad on the Guatemalan frontier is being fast pushed to completion. By January 1, 1910, it will be possible to go by rail from the United States through Mexico to Guatemala City.

From Jalisco comes news that the Buena Fé Mining Co., operating near Ojuelos, is erecting a large plant, including a gas-producer using charcoal, a Westinghouse three-cylinder gas-engine, which will be used to drive an electric generator and an air-compressor. Electrically driven station and sinking pumps will be used in the mines. The G. & O. Braniff Co. supplied the plant. As the result of the new protective tariff on coal, the coal-mining camps of Coahuila are becoming prosperous. The Mexican Coal & Coke Co., which is operating mines at Esperanzas, has recently placed orders for a considerable amount of extra machinery, including an 1100-hp. Schoendube and Nengebaur steam turbine and condenser, which will be used to drive an A. C. generator; also a number of transformers, motors, and accessory electrical apparatus. The same company has also ordered 16 Sulzer pumps, the largest being a 350-hp. multi-stage centrifugal.

The Chapanal mine, near the old Quecillas mine in the district of Zacualpán has been sold by the Rodriguez Bros. to a company in the City of Mexico, and the construction of a stamp-mill and concentration plant has already been commenced. Electric power for this plant will be obtained from the Seguranza Mining Company.

Various opinions are expressed regarding the new mining law, which will go before the Mexican Senate during the month of September. Some are of the opinion that extensive changes will be made, but authoritative opinions expressed in high governmental circles are to the effect that the bill will probably go through the Senate practically without change, or only with minor modifications.

The deal for El Tigre mine in Sonora has fallen through. The mine was to have been sold, two-thirds for \$4,000,000, to New York and South African capitalists. Payment of \$250,000, to have been made August 21, was not forthcoming, and the sale is off. This mine was bought a few years ago by Kansas City people for \$600,000. They then had a lawsuit which cost \$250,000, but none the less have done well. The mine has been paying 7% per month on the capitalization of \$600,000. The Mexican company is El Tigre. The American company owning the stock is the Lucky Tigre, of Arizona.

GUADALAJARA, MEXICO.

Oro Grande Mines Co. — New Reduction Plant. — Amparo Mines. — Aguascalientes Metal Co. — Smelter in Guerrero.

The Oro Grande Mines Co. has just been launched in the United States to take over, re-open, and further develop the famous old La Luz, Refugio, Bolañitos, Melladito, and Tolentino mines in La Luz camp of Guanajuato, and to erect a reduction plant with a daily capacity of at least 1000 tons. It marks the second attempt to carry out these projects, as the Refugio Mines Syndicate was organized several months ago to work along the same lines. However, the flotation did not prove successful, and the stock was withdrawn from the market. The new company has a capital of \$9,250,000, of which \$2,750,000 is 6% cumulative preferred, and the remainder common stock. William R. Roney is president; George W. Bryant, vice-president and resident director in Mexico; John H. House, secretary, and Frank G. Peck, treasurer. The old mines number 38, and they are credited with a past production of fully \$100,000,000. The dump contains approximately 500,000 tons of ore, and there is much low-grade ore in the old workings. According to the plans, the reduction plant to be erected shortly at the Tajo de Dolores mine, in the Guanajuato district, will be one of the most complete in Mexico. It will consist of rock-breakers, forty 1350-lb. stamps, concentrators, 2 tube-mills, 8 Pachuca leaching tanks, and 2 filter-presses. The sand leaching plant will be dispensed with, all sands being re-ground, and everything reduced to

slime. The ore now blocked in the Tajo de Dolores amounts to 360,000 tons. The property is held by the Proprietary Mines Co., of New York. Difficult engineering work in connection with plans for unwatering the San Cayetano mines in the Guanajuato district has been completed, and the old workings will be now drained. The Lewisohns of New York are principally interested in the properties, and the mines will be thoroughly examined following the unwatering. Extensive development is likely.

The Amparo Mining Co., of Philadelphia, operating in the Etzatlan district of Jalisco, has just paid its third quarterly dividend of 2½%. In July 5010 tons of ore, averaging \$26.50 per ton, were treated in the Amparo reduction plant, and high extraction was secured. Patrick Blalack, president of the Quien Sabe Mining Co., which has been operating the Quien Sabe mines at Ajilic, Jalisco, on the northern shore of Lake Chapala, recently cleaned up over \$2,000,000 in land in and around Brownsville, Texas, and he will invest much of the money in mines in this portion of Mexico. The Quien Sabe properties do not constitute as big a proposition as Mr. Blalack desires, and they have been shut down pending a sale. S. C. Prunty, form-

State of Jalisco, Mexico.

erly with the San Luis Potosí smelter, is representing Mr. Blalack in this field, and other properties will be taken up and developed. The new reduction plant of the Tajo Mining Co., at the Tajo mines in the San Sebastián district, is working satisfactorily, the extraction being high. Thirty tons of ore, averaging \$30 per ton, are handled daily. The gold in the ore is sufficient to cover the mining and milling expenses, leaving the silver as profit. The Tajo mines are *antiguas* which produce about \$12,000,000.

A new body of ore has been opened in the properties of the Guggenheim interests in the Tepezalá camp of Aguascalientes, and there is now promise that these mines, which were believed to be giving out, will continue to produce heavily for years. In the Santa Francisca silver mine, in the Asientos camp of Aguascalientes, copper is appearing in depth, and the main shaft is now being put down to a depth of 260 metres (853 ft.). The Aguascalientes Metal Co., operating in the Asientos camp of Aguascalientes, has opened a shoot of rich copper-silver ore in its Orito property, and is sinking to a depth of 540 ft. The company is shipping more than 1000 tons of ore monthly to the Aguascalientes smelter. The Lead Queen Mining Co., of Aguascalientes has purchased the Tajos de Purísima mine in the Asientos camp from Francisco Morán. This is a promising lead-silver property. The Maine & Nebraska Mining Co. has completed a 100-ton smelter at its mines near Balsas, State of Guerrero, and the plant will be soon in operation. A railroad has been built from Balsas to the properties, a dis-

tance of five miles. The ore is an iron sulphide carrying gold, silver, and copper. F. M. Currie, of Broken Bow, Neb., is at the head of the enterprise.

BUTTE, MONTANA.

Copper Output.—Zinc Concentrator.— Sierra Mining Co. — Keating to Issue New Stock —British Butte.

Due to the fact that the Mountain View mine of the Boston & Montana Co., one of the Amalgamated subsidiaries, was closed nearly all month, the copper production of the Butte district in August shows a considerable decrease. The Mountain View yields about 650 tons of ore per day when operated to full capacity. The total production of the district for the month is estimated at 26,070,130 lb., the different companies contributing about as follows:

| Companies. | Ore, tons. | Copper, lb. daily. | Copper, lb. month. |
|-----------------------|------------|--------------------|--------------------|
| Boston & Montana.... | 3,200 | 243,200 | 7,052,800 |
| Anaconda | 3,605 | 223,510 | 6,481,790 |
| Butte & Boston..... | 650 | 40,950 | 1,187,550 |
| Washoe | 555 | 34,410 | 997,890 |
| Parrot | 390 | 22,620 | 655,980 |
| Trenton | 400 | 24,400 | 707,600 |
| North Butte | 1,390 | 116,760 | 3,386,040 |
| Butte Coalition | 1,500 | 108,000 | 3,132,000 |
| Original | 700 | 51,100 | 1,481,900 |
| Pittsburg & Montana. | 390 | 26,520 | 769,080 |
| Miscellaneous | 100 | 7,500 | 217,500 |
| | 12,880 | 898,970 | 26,070,130 |

The Butte & Superior Copper Co., which owns the Blackrock group of claims, will for the present pin its faith on the zinc ore deposits in the Blackrock, and has decided to erect a 300-ton zinc concentrator at the mine. The Blackrock contains an immense tonnage of zinc ore. W. A. Clark has built a large zinc plant at the Butte Reduction works for the purpose of treating ore from some of his mines. The Butte & Superior has been trying to find copper ore in paying quality and quantity in the Blackrock, but not with good success. The intention now is to concentrate the zinc ore regardless of the copper content. A 300-ton mill is a small concern considering the great quantity of zinc ore in the Blackrock mine. The new zinc mill is to be completed within five months, a contract for its erection having already been let. Engineers and others representing W. A. Clark have made some excellent reports on the zinc deposits in the Butte district, and have predicted that zinc will become of greater profit to Butte miners than copper. The district contains some of the largest zinc deposits in the world. The Alice group of mines, now owned by the Butte Coalition, has millions of tons of the ore in sight. The same is true of the Lexington mines owned by La France Copper Co., a United Copper Co. concern, and the old Emma mine, owned now by the Butte Copper & Zinc Co., a New York corporation owned by the Seligmans and associates, also has several million tons of high-grade zinc ore in sight. A great deal of zinc ore exists in the old Blue Eyed Nellie mining district west of Anaconda, the ore averaging about 36% zinc.

It would appear that the flotation of the Sierra Mining company, organized by Thomas F. Cole, of Duluth, was not the great success that was at first advertised. The announcement was that the stock had been greatly over-subscribed, but the later information was that everybody would get all they had asked for. The allotment was postponed from time to time. It is understood that the enterprise is one fathered alone by Mr. Cole, and is not one of the so-called Cole-Ryan propositions. Three hundred thousand shares of the stock have been offered for subscription at \$6 per share, \$4 more to be collected later. The Sierra is said to own several thousand acres of land in Mexico, including a lot of valuable timber and some old mines that were worked by the Spaniards years ago.

Stockholders of the Keating Gold Mining Co. received a surprise package from the directors in the form of an announcement that a special meeting would be held October

2 for the purpose of increasing the capital stock to \$2,000,000, the object being to provide more stock to raise money if possible. The stockholders had always been given to understand that the mine was paying well, and that dividends were in sight. The statement of the directors, however, indicates differently. It also develops that there is no stock left in the treasury. Considerable of the stock has been distributed in New York and elsewhere in the East.

Stockholders of the Butte & Ely Copper Co. have received notice that they are expected to contribute 10% of their private holdings to the option given Thomas F. Cole, of the Giroux Consolidated company, in order to make up a majority of the stock, and a condition imposed by Mr. Cole is that he shall have control. The directors gave him an option on the stock remaining in the treasury, amounting to 229,175 shares, at \$1 per share, payable on or before September 14. The stockholders are asked to contribute sufficient more at the same price to make up at least 250,005 shares. The stock has for some time been selling at about \$2 per share. While the option stands in the name of Mr. Cole personally, there is no doubt that he holds it for the Giroux company and the Cole-Ryan syndicate.

Although the British Butte Mining Co. is now making weekly clean-ups and shipping gold to the United States Assay Office from its dredge west of Butte, small stockholders in Montana who have grown tired of holding British Butte stock, have discovered that there is no market for the shares anywhere, although there was at one time considerable trading in them in London. The last quotations, however, were 8c. per share, and for some time not even one cent has been offered. The C. W. Syndicate of London practically owns the company, and its manager in Butte is the controlling authority. No directors' meetings have been held and no reports are made. The company is capitalized for 5,000,000 shares at \$1 par, and in addition to that the C. W. Syndicate has advanced several hundred thousand dollars, which is understood to be unsecured, and is hanging over the company as a claim that may be made preferred at any time.

GOLDFIELD, NEVADA.

Consolidated Mines Co. — Year-End Dividend. — Combination Estimating Ore Reserves.—Florence Mill Increase. — Discovery on Columbia Mountain.

It is announced by the management of the Consolidated Mines Co. that the directors, at their quarterly meeting in November, will consider the project of enlarging the capacity of the 100-stamp mill on Columbia mountain, and it is probable that at that meeting an extra dividend will be declared. After the payment of the July dividend there remained over \$1,000,000 in cash in the company's treasury, and profits have accrued at a rate which will render possible the distribution of an additional 30c. dividend before the end of the current year. This reserve fund will be materially augmented by receipts from the shipment of high-grade ore. A large amount of ore of this character is ready to ship, and it has accumulated to such a degree that at several points its presence impedes progress in development. For this reason shipments will be resumed at once from the Hampton stope and other points, particularly from the 403-ft. level of the Mohawk.

This company's mines are producing at the rate of approximately 22,000 tons monthly, of which 10,000 tons is from the Mohawk, 6000 from the Red Top, and 6000 from the Combination. The only production as yet from the Clermont is a comparatively small amount which is extracted in the course of development at the 730-ft. level, where the orebody is maintaining its early promise, the grade remaining well above the top milling limit. At the 860-ft. level low-grade assays are being secured in the cross-cut which is being driven for the same ore-shoot as above, but the ore is still some distance ahead. A powerful station-pump has been installed at the 1000-ft. level, the electric installation for its operation is completed, and extensive development will at once proceed from this station with the Mohawk vein, believed to be 400 ft. distant from the shaft at this depth, the first objective point. At the 600-ft. level

another 150 ft. should bring the north drift into the Lucky Boy orebody at a point where it turns sharply to the west from its north and south course from the Red Top. This vein is now opened on the Red Top at the 330-ft. level and driving is in progress both north and south from a point east of the Red Top shaft, with an apparent improvement in the character of the vein at this depth over that exposed on the upper levels.

Ore is being stoped at the southern extremity of the Combination workings in territory adjoining the famous Reilly lease on the Florence, the stopes being at the fourth level; and the ore has been cut at the sixth level as well. From this point to the main Combination shaft the workings at two levels are entirely in ore for a distance of 700 ft., and J. H. Mackenzie announces that the ore will be stoped to the surface, an operation that will result in a gigantic 'glory hole' for the entire distance and from 50 to 60 ft. in depth from the surface. The same methods will be pursued on the Red Top. During the coming autumn, probably in November, a complete survey of the mines will be conducted upon which to base a careful estimate of the value of this company's ore reserves. They have been added to greatly during the past six months, and will show some interesting figures, despite the fact that the value of ore taken out during the year will be in excess of \$5,000,000. Included in the company's recent work in a tunnel which is being driven from the line of the Cornishman claim of the Florence to tap the veins of the early leases on the Jumbo, the first point to be reached being the early workings of the Zinn lease, from which a large quantity of exceedingly rich ore was mined over four years ago. This territory has not since been touched. The giant stopes between the 450 and 600-ft. levels on the dividing line between the Mohawk and the Jumbo, are yielding a large tonnage of good ore, and a winze has been sunk from this point 50 ft. below the 600-ft. level, and a drift started from the bottom of the winze, which has been timbered, owing to the strong flow of water.

Within a few days the Florence mill will be operating at an increased capacity, treating 160 tons of ore per day. The new tube-mill, Card concentrators, and plates, are in place, and all is in readiness to handle a largely increased tonnage. The aerial tramway is now conveying ore from the Little Florence workings to the mill-bins, and development is in progress throughout the mine, with hundreds of feet of stopes opened, and a vast tonnage of excellent ore exposed at all levels down to the 500-ft., the deepest point in the mine. It is probable that a winze will shortly be sunk to prospect the Engineers' vein below the 500-ft. level, as the high-grade ore is exposed at this level. Mr. Lockhart has always believed this to be the richest vein on the Florence. The present ore-production of the Diamondfield portion of the Goldfield district is approximately 25 tons of ore per day, averaging fully \$75 per ton. With the opening of the ore-shoot in the old Detch stopes of the Millard-Jones lease on the Daisy, and with resumption of the Diadem lease on the Great Bend, this output will be materially increased. The Daisy company, while devoting but one-tenth of its work to production, is shipping 10 tons of \$75 ore per day, and has opened good ore in the old workings near the original incline shaft at the eastern end of the group. Development is constantly adding to the ore reserves. The Golden Daisy lease is shipping five tons of \$125 ore from the vein opened at two points on and above the 360-ft. level, and is blocking out reserves of rich ore in a shoot of excellent proportion. The Goldfield Belmont is shipping 70 tons per week from the lease-workings in the upper levels, and the company is developing a blind lead cut recently at the 200-ft. level. Unwatering of the shaft is being done in preparation for extensive development on the deeper levels.

At a depth of 110 ft. in a shaft sunk near the peak of Columbia mountain pay-ore has been exposed with seams revealing free gold, and assaying up to \$3000 per ton. The vein shows 3 ft. of good ore, with but one wall exposed, and the lessee, B. E. Thomas, has secured the privilege of using the company's tunnel which was driven 1300 ft. into the mountain from its base, and which will be continued to the vein by the lessee. The discovery has created keen interest, and a renewed demand for leases on inside territory. Some

rich samples of ore have been brought in from the Blue Bull upon which lessees opened the ore in a winze from a tunnel and have now cut the ore-shoot in a cross-cut from the shaft at the 150-ft. level. The adjoining Imperial has resumed, and a double-compartment shaft is being sunk, with low-grade ore appearing. The Nancy Donaldson shaft, in the eastern part of the district, has been timbered to the 100-ft. level and sinking has been resumed. Rich ore has been found on this ground at the surface, and at 18 ft. in depth in the shaft. An Eastern company, the West Trent Gold Mining Co., has started sinking a new shaft at a point two miles west of Goldfield, and will sink to the 400-ft. level before starting lateral development. Lessees operating on the Poleverde claim, the joint property of the Consolidated and Jumbo Extension, are sinking two shafts which will extend to the 1000-ft. level, as provided in their leases. They will be fitted with substantial timbering of Oregon pine, 10 by 10 in. for the last 500 ft. These shafts will cut the Clermont and other veins. One of the shafts is that of the former Goldfield Annex lease, already down 350 feet.

LOS ANGELES.

Developments in Coyote Hills.—Central Oil Co.—Gusher at Whittier.—Lompoc

Among the recent important developments in the fields south of the Tehachapi are the striking of oil in the Union's well in the Coyote hills and the Central's new well in the Whittier field. The Union's well is situated on the Bastanchury lease, six miles south of the Olinda-LaBrea Canyon fields and about a mile east of the Murphy Oil Co.'s productive wells in the Coyote hills. The oil was struck at about 4400 ft., and though nothing spectacular resulted when the sand was penetrated, the well is believed to be capable of good production. This is the second hole the Union has drilled on this lease, the first being spoiled in drilling, and nearly three years has been consumed in getting results. It is always a serious matter to put a hole down over 3000 ft., and the Union is to be commended for its perseverance in testing deep territory, not only in the Puente hills district, but in other parts of the State.

The Central Oil Co. has been rewarded in prospecting toward the eastern end of the Whittier field by bringing in a gusher of 32° Baumé oil last week. The productive stratum was encountered at about 2500 ft., oil spouting high over the derrick intermittently for several hours when the drill penetrated the sand. About 2000 bbl. was produced before the well ~~stayed~~ ^{stayed} up, but only about 500 of this was saved. It seems ~~too~~ ^{bad} that the usual accompaniment of striking a gusher is the wasting of a big percentage of the first flow. Another well in which the recent striking of productive strata is important is No. 2 of the Lompoc Oil Development Co. in the Lompoc field. Like the Union's Bastanchury, this is also the second well of the Lompoc company, its first on the same property being a failure on account of flooding water. No. 1 was nearly 3900 ft. deep; No. 2 struck the sand at about 3600 ft. This new well is the farthest east of any which has struck the productive zone on the Purisima hills anticline, and extends the proved territory for a considerable distance east of the heretofore developed ground. The reported strike of oil in the Devil's Den Consolidated well in the Devil's Den district should be received with some incredulity, as many of the accompaniments of the 'strike', such as the posting of 'no admittance' signs, and the ordering of inquisitive strangers off the property, lead to the conclusion that there is something about the well that needs concealing. The hole may contain some gas and oil, but it takes more than these indications and secretiveness to prove the productivity of a new territory.

The reported purchase of the Brockton lease on Sec. 23, T. 32 S. R. 23 E., Midway district, by the Palmer Oil Co., is interesting as corroborating the rumored policy of expansion of this thrifty company. With one of the greatest wells in the State (the Palmer No. 1 of the Cat Canyon field, Santa Maria district), to its credit, this concern ought to be in a position to build up a good size group of properties.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Speed in lead-smelting with the blast-furnace varies materially with the percentage of sulphur in the charge, the other constituents maintaining approximately fixed proportions. A difference of 1% in the matte-fall will often increase the capacity of the furnace from 8 to 10 tons per diem. The sulphur elimination in blast-furnace lead-smelting may be as great as 30 per cent.

Spitting of ores in scorification may be due to many causes, most commonly to dampness in the scorifier. Other causes are imperfect mixing of the charge, too low an initial temperature in the muffle, too deep a scorifier, and too early an admission of air into the muffle. To prevent spitting of lead, when the size of a lead-button is being reduced by scorification, it is important to heat the scorifier before introducing the lead.

Iron sesquioxide, Fe_2O_3 , forms silicates which are extremely infusible, hence this oxide is undesirable as a base for slags, and in roasting copper ores for smelting the effort is to produce as large a proportion of the ferrous oxide, FeO , as possible. As the FeO cannot exist in the free state some of it is further oxidized in roasting to Fe_2O_3 , and part unites with ferric oxide to form Fe_3O_4 . In the blast-furnace the higher oxides are reduced to FeO by the CO formed from the combustion of the fuel.

Olivine is a constituent of most basic igneous rocks, such as peridotite, norite, basalt, diabase, and gabbro. It does not normally exist in silicious rocks, since the fusion of olivine with silica produces enstatite. As the silicious content of an igneous rock increases, the olivine is replaced by pyroxene. But there are exceptions to the rule, and olivine is occasionally found in such highly acid rocks as trachyte, and it is not uncommon as an accessory in andesites. It is sometimes formed in limestones when these have been metamorphosed by heat in proximity to volcanic intrusives.

Chromite is the only commercial ore of chromium, and it must contain at least 50% of the metal to possess a market value. The pure mineral contains 68% of chromium. It is usually massive, and black in color. It also occurs disseminated as grains through the rock. As its specific gravity is moderately high (4.3 to 4.6), it is readily amenable to concentration. This mineral is essentially a constituent of peridotites, and of the serpentines resulting from their alteration. The price at Eastern markets for 50% ore and better, ranges from \$15 to \$20 per long ton.

Heating coal to moderate temperatures, that is, below the boiling point for water, causes the evolution of gases of the paraffin series, such as ethane, propane, and butane. These gases, which make highly explosive mixtures with air in certain proportions, are obtained from anthracite as well as

from bituminous coal. Recent experiments have shown also that these gases are evolved during the crushing of coal. The manner in which the gases are held in the coal is not definitely known. They may exist in the crevices, or may be held intimately distributed through the intermolecular spaces, in a manner analogous to solution.

Pot-roasting is a system of partial desulphurization of ores of lead or copper, by a down-draft through the bed of the ore. It is useful with flue-dust and fine ore for sintering it, thus preparing it for the blast-furnace. This material is dampened and spread over a grate upon a primer of ignited sulphides. The grate constitutes the bottom of a circular receptacle of cast-iron. With lead ores lime is mixed with the charge in proportions varying from 7 to 10%, but that is not needed with copper ores. The lime-roasting of lead ores is employed at many plants, but is by no means universal.

Sulphur in Utah comes from rhyolitic tuffs in Beaver county, which are impregnated by emanations from a fissure which still emits sulphuretted hydrogen. The locality is at Black Rock, where native sulphur is produced to some extent. The rock is mined in a crude way, and the sulphur is then melted out of it in iron retorts, using steam giving a temperature of 144°C . The liquid sulphur is drawn off, and when cooled is ground and sacked for shipment. Louisiana dominates the sulphur market of the world. The imports into the United States have dwindled from 127,996 long tons in 1904, to 19,620 in 1908, the corresponding values being \$2,462,300 and \$318,577.

Cassiterite, tin oxide, may be most easily determined by placing the mineral in dilute hydrochloric or sulphuric acid with granulated, sheet, or shot zinc. A rapid evolution of hydrogen ensues, which reduces metallic tin upon the surface of the cassiterite fragment. The metallic coating is dull gray in color, but becomes bright on rubbing with a soft cloth or chamois-skin. At the same time the peculiar tin odor is emitted, which is so characteristic as to confirm the test. The reaction on which this reduction depends is:

It is more prompt when hydrochloric acid is employed.

Cyanide poisoning cannot be successfully treated by hydrogen peroxide alone. Indeed that substance is of no utility as an antidote except when used by hypodermic injection. It should always be fresh, that which has been previously opened and exposed to the air being useless. Freshly precipitated ferrous oxide given internally is a perfectly efficient remedy if administered promptly. To be ready to prepare this keep on hand two bottles, one containing $7\frac{1}{2}$ gm. ferrous sulphate dissolved in 50 c.c. distilled water, and one of 400 c.c. capacity, containing 250 c.c. of a solution of $1\frac{1}{2}$ gm. caustic soda, and 2 gm. magnesia. Pouring one into the other produces the ferric oxide. After administering, employ a stomach pump. Wedges will be needed to keep the teeth of the patient apart during this treatment.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Co-operative Topographic Surveys.

The Editor:

Sir—May I call attention in your columns to some phases of co-operation in topographic surveys which do not seem to have been considered by George Otis Smith in his letter in your issue of June 19? He says in substance: (1) that the special claims of the public-land States, where the Federal interest in the adequate mapping is paramount by reason of public ownership of land, and (2) that the progress of the topographic map of the United States as a whole, are the two general considerations which must govern the distribution of the topographic surveys in various portions of the United States until specific progress is made in the appropriation for co-operative work.

Let me ask, does public ownership of land necessarily constitute a special claim for a United States Geological Survey contour topographic map of such land? I think not. Do we need contour topographic maps of vast stretches of plain or prairie which are not yet homesteaded, and on which little or no population resides, simply because this land is Government land, as much as we need such maps for thickly settled regions where farming is intensive, and roads are building, where towns exist, mines and quarries are being worked, and where other development and administration problems press? Suppose a given State to contain entirely public land. The adequate mapping of such land would consist of subdividing it for homesteads, surveying its forest boundaries, making appropriate reclamation surveys, and surveying or mapping its rivers and harbors for possible improvements. For all this work the Federal Government has other organizations and appropriations. There would be no population aside from national officials in such a territory to call urgently for the complete maps of the United States Geological Survey, and these completed maps would be paid for by the people of the other States which were refused such surveys because they contained no public land. The appropriations made to the General Land Office, the Forestry Bureau, to the Corps of Engineers of the War Department, and to the Reclamation Service, should care for the paramount Federal interests in the public-land States, leaving the United States Geological Survey to care for the adequate mapping of the more intensely developed regions, be they regions in public-land States or States in which there is no public land whatever.

Supposing in another State the United States owned not an acre. This fact alone would mean a thickly populated country whose citizens needed detailed contour topographic maps for solving their problems of intensive agriculture, of sewerage, and water-supply, of highway, railway, and canal construction, of water-power development, of flood pre-

vention, of mining and quarrying, and of many other projects of urgent need and immediate value. Density of population and intensity of development should be the guiding principles for distributing the topographic surveys of the United States Geological Survey rather than Federal ownership of the soil-rights.

As to the Director's second consideration, the scheme of gradually decreasing allotments suggests the traveler who each day rested after completing one-half of the remainder of his journey. It seems to set up as ideal the completion of the whole United States simultaneously, disregarding the fact that some of these States might be in sore need of a complete map of its area 20 years before the work would be done, and another State might not be in such pressing need until 20 years after. The defects in the proposed scheme are clearly shown when applied to the State of Ohio, where it works a severe hardship, not to say an injustice. In 1900 a representative of the U. S. Geological Survey presented to the general Assembly of Ohio an estimate wherein it was proposed to complete the State survey in 8 years with annual appropriations of \$50,000, divided equally between the State and the United States. Acting upon this, the legislature appropriated the \$25,000 with which to begin the work, and has done so faithfully each year since, expecting to see the State mapped completely by the expiration of 1908. However, owing to a mistake in the estimate, and to welcome improvements in the surveys and maps, under the original scheme Ohio would not have been mapped until 1912, as the cost is averaging about \$15 per mile instead of \$10. But meanwhile the cuts in the appropriation for the topographic branch made by Congress, and above all the new proposed scheme of the Director of the Survey, have deferred the completion to the uncertain future. At this writing there are surveyed only 122 out of the 212 fifteen-minute quadrangles necessary to complete the State survey, and no one can now see the end of the survey, so far as the United States Geological Survey maps concern Ohio, under the new scheme.

Ohio's urgent canal-questions must wait until some State which has its canals yet to build is surveyed; her flood prevention problems must remain unstudied until the survey of some States whose valleys are scarcely yet settled, is nearing completion; her minerals, forests, soils, on which five million people dwell, cannot be studied as a whole until some State with scarcely as many hundred thousand has its domain practically mapped complete.

That the need for a complete map of this State is real and not fancied is illustrated by the work now in progress on the State road-map. The Ohio State Highway Commissioner received from the Legislature last March an appropriation of \$5000, with which to complete before the end of the year a road-map of each county. With about 65% of the actual area of the State surveyed by the United States Geological Survey, only 22 out of the 88 counties are completely covered by those maps, leaving the remainder to be filled in from such meagre other data as can be obtained.

Columbus, Ohio, August 9.

C. E. SHERMAN.

Divergence of Plummet-wires in Deep Shaft-Surveying.

The Editor:

Sir—I beg to say that recently my attention was directed to a discussion in your paper as far back as October 5, 1907, by F. W. McNair, President of the Michigan College of Mines, which had previously escaped my notice. It is a criticism of my article published in your issue of August 25, 1906, upon a quick method for surveying a vertical shaft. The article would be apt to lead one to believe that my survey of the Oneida vertical shaft might contain an abnormal error in azimuth on account of an abnormal divergence of the plummet-wires. The principal object of measuring the distance between the wires was to be sure that they were hanging free as a check upon the examination of their positions in the shaft throughout their entire lengths below the points of suspension.

My survey of the Oneida vertical shaft checked to one minute of arc in azimuth through the 1200-ft. level, and an independent connection previously made through an incline shaft to the surface. Nor was this close check a mere accident. It was due to the special care used in fixing the positions of permanent rest in the vertical plane of the wires on the templates, and in setting the wires thereto with the precision necessary for close practical results, the amount of their divergence being only a secondary consideration. Had this check, which was not mentioned in my original article (as it was not material to the description of the method), not been available, it would then have been necessary for me, under the circumstances, to have repeated the survey for a check, preferably in another compartment of the shaft, as no engineer would be justified in basing the continuation of any such survey on data, the reliability of which he was not sure of.

I have made check surveys using soft-drawn wires and heavy bobs in other shafts in widely separated compartments for the purpose of getting said surveys into as dissimilar disturbing conditions as possible, and have obtained results so close that they did not indicate that air-currents, falling water, and magnetic conditions, appreciably affected the azimuth. This was confirmed by subsequent connections I have made from such surveys. In these check surveys the transit was set up closely to the true vertical plane of the wires, and used to help determine the positions of permanent rest, which in every instance was quickly done.

Another well known refinement may be used, although I have never had occasion to use it, namely, a finely divided scale, to be placed on the template and used in conjunction with the transit in noting the oscillations for determining the position of permanent rest. This, I think, could be done, with extreme accuracy, provided that each bob was heavy enough to sufficiently resist the disturbing influences, particularly those of falling water if in a wet shaft. Ordinarily, the engineer need not dwell too much upon the importance of these disturbing influences, nor always make check surveys to be sure of good results.

A number of years before Mr. McNair experi-

mented in the Tamarack mine with the 'side shot' method of placing the wires, I used it with good results, but have long since abandoned it, except in rare cases, in favor of the 'jiggling in' method, wherein the base between the wires is usually much shorter and in general is only about one-third as long. Notwithstanding that the base is so severely shortened, it is my experience that the advantages are decidedly with the 'jiggling in' method, for with it the engineer can use his transit directly, an impossibility in the 'side shot' method, to assist in setting the wires to their positions of permanent rest and afterward in getting the alignment from them. The alignment is thus obtained with greater precision than is possible with the 'side shot' method, generally enough so, I think, to more than compensate for the severe cut in the base between the wires, particularly since the personal equation of but one man, the engineer, will in common practice affect the accuracy of the operations.

An objection is made that 'jiggling in' is a tedious process, and so it is when the wires are not set at permanent rest, but when they are, the difficulty vanishes, and the alignment may be quickly taken with great precision and a large number of levels quickly, directly, and reliably tied in. In regard to the cause of the abnormal divergence of the plummet-wires two-hundredths of a foot in a depth of 2000 ft. in the Oneida vertical shaft on July 6, 1902. I have come to the conclusion that neither Mr. McNair nor myself were right in our speculations. I now ascribe the cause to the mode of setting the wires in their positions of permanent rest to their respective templates from underneath. This was done by drawing the bobs in opposite directions, substantially within the vertical plane of the wires toward the wall-plates of the shaft, and fastening them thereto, causing said wires to press hard against the templates. As these templates were made from pieces of the soft wood of a candle-box, the wires cut into and forced them apart, changing the settings enough to account for this abnormal divergence. This operation, however, did not, nor could, materially alter the location of the vertical plane of the wires, as all of the pressure exerted against the templates was virtually within said plane, and, therefore, the accuracy of the survey was thereby practically unaffected.

W. E. DOWNS.

Sutter Creek, California, July 31.

Progress in Cyanidation.

The Editor:

Sir—George Mackenzie may reasonably endeavor, in your issue of July 17, to take exception to my conclusions, but can scarcely be justified in objecting to my statement of facts seeing that it absolutely agrees with Mr. Hall's statement, which he includes in his letter although it was omitted from his similar letter to the *South African Mining Journal* of May 29; an omission all the more strange as the charges in the letter were supposed to be based on Mr. Hall's report. The absolute agreement of Mr. Hall's figures with my own is natural as he was the source of my information as to the Ferreira work.

It is obvious from Mr. Hall's report that at the Ferreira, instead of collecting, dissolving, and washing in one vat by one process, Mr. Hall collects in one series of vats, agitates for the purpose of getting the gold into solution in another series of vats, and then transfers to another series (fitted with the Adair-Usher apparatus) for the washing, precisely as I stated. He thus confirms the conclusion to which Mr. Mackenzie takes such strong exception; "the Adair-Usher process thus becomes a method not of solution but of avoiding, with the aid of decantation, a final transfer." As for the claim to avoid the necessity of any settling, Mr. Hall's report is conclusive. I stated that "a flow of solution at the rate of 10 to 12 tons per hour was maintained for a 150-ton charge for 36 hours out of a total treatment time (in the Adair-Usher washing vat) of 72 hours." Mr. Hall is even more conclusive; he states, "the average weight of a charge is 150 tons; in the Usher tank, solution is run through at the rate of 12 tons per hour for 36 hours. Another 36 hours is allowed for settlement, decantation, and discharge." There is no doubt, therefore, as to the settlement. It must be remembered that the Adair-Usher process claimed to be a solution-process as well as a washing process.

As for my conclusions, they may be absolutely mistaken, as may have been also the criticisms on the process in the *Journal of the Chemical, Metallurgical & Mining Society* for July and August 1908, and notably the unanswered criticisms of H. A. White, but whether they are mistaken or not, as the criticisms in my annual Christmas Letter of Progress were never intended for publication (see my protest in the MINING AND SCIENTIFIC PRESS of February 20, 1909), Mr. Mackenzie will, I am sure, acquit me of any desire to prejudice the public against his process.

With your permission I will conclude with an extract from my reply to Mr. Mackenzie's similar letter in the *South African Mining Journal*. "The Adair-Usher people have admittedly worked hard and no one would be more pleased than myself at their reaping so large a pecuniary reward for their efforts as to adequately recompense all concerned; for their efforts have undoubtedly resulted in demonstrating that certain of the existing decantation plants in South Africa were capable of being worked to better advantage."

ALFRED JAMES.

London, August 13.

Platinum and Gold Losses in Dredging.

The Editor:

Sir—Under the heading 'Platinum and Gold Losses in Dredging', in your issue of August 14, the figures of the tests carried out by W. H. James are substantially correct, excepting the "losses per cubic yard of gold and platinum." In your tabulated statement of the tests these equal, and in the latter case far exceed, the original value of the gravel, which was given in fractions of a dollar, instead of in fractions of a cent.

THOS. H. LEGGETT.

New York, August 23.

Waihi Gold Mines.

The Editor:

Sir—From the last annual report of the Waihi company, you will note continued progress; the policy of the company to make a record output each year is being continued, consistent with the best mining, metallurgical, and commercial practice. The ore is also now developed and ready to make further records during this year, 1910, '11, and '12; while not one pound of ore below the 850-ft. level (which is 150 ft. above No. 9, now being opened) has been included in the ore reserves. Already at the 1000-ft. (or No. 9) level it seems clear that the lodes, of which there are 16, are likely to be much stronger than above; the Empire and the Royal, the only two intersected so far, running up to 40 ft. in width, while overhead they did not exceed 20 ft. This widening of the veins with depth has been a feature of the mine for the last four or five levels, and at No. 8 (850-ft.) level the Edward made an enormous lens which at its apex is 95 ft. wide, and averages \$50 per ton for the whole width. There has been nothing better in the mine, though wider stopes are being worked on the Martha lode, also highly payable.

The company conducts its finance on exceedingly conservative lines, and now has liquid cash assets of over \$2,000,000, while every year it writes off about 10% of costs for depreciation of plant; at the same time it also charges an average of \$200,000 for capital expenditure to its revenue account. By this process the book-value of the mine and plant, which cost over \$5,000,000, is written down to \$1,800,000, while the market value of the property stands at over \$22,000,000. The dividends paid to date exceed \$16,825,000, and the return on the investment for some years past has averaged 10% to shareholders, the object being to make the stock a standard investment by extremely even returns.

The mining and milling costs are steadily decreasing, and for 1908 amounted to \$3.95 per ton of 2000 lb. This does not include 30¢ for development. The ore-treatment process is complex, and the plant is probably the most complete of its kind in existence. The ore passes through all the ramifications of rock-breakers, stamps, tube-mills, amalgamating tables, and vanners, to the separate plants for leaching sand, agitation, and vacuum basket-filtration of slime, treatment raw by cyanide, and extremely fine grinding of the concentrate, and final refining of the bullion into pure gold and 0.998 fine silver bars.

A. E. Drucker, a Californian metallurgist, has just spent two or three weeks studying the Waihi mills.

CHAS. RHODES.

Auckland, New Zealand, June 24.

Bromine is chiefly produced from brines in Michigan, Ohio, Pennsylvania, and West Virginia. The output is about 1,000,000 lb. per year, worth about 10¢ per lb. The bromine usually occurs as a bromide of magnesium, the quantity seldom exceeding 2 grams per litre, and in the brines from the Saginaw river field in Michigan, the quantity is often as low as 0.35 gm. per litre. The market is dull, and much of the bromine produced in 1908 remained unsold at the end of that year.

GEOLOGY OF NORTHEASTERN MEXICO.

Written for the MINING AND SCIENTIFIC PRESS
By R. H. BURROWS.

(Continued From Page 294.)

The most striking phenomenon seen in the Las Vigas copper deposits, is their general distribution along the sandstone outcrops. Probably a length of 20 miles along the edge of the beds was passed over, and at every point where the sandstone horizon was visible, considerable copper ore was encountered. This at times would be represented by a mere stain of green carbonate, but the continuity of mineralization was unbroken, showing clearly that the mineral was not limited to any local impregnation as is the case in so many ore deposits. The outcrops of the copper sandstones are found distributed over an area 50 miles long by 12 miles wide, equal to 600 square miles. The mineralization of this formation over such an extensive area is hardly paralleled by the Kupferschiefer of the Mansfeld district in Prussian Saxony. Eruptive agencies, which are generally coupled with the impregnation of metalliferous beds, are nowhere in evidence in the district covered by the Las Vigas formation. Whether the copper may have been originally disseminated through the body of the formation, and subsequently concentrated near the planes of movement, or whether the mineral was introduced into the fissures after the crumpling and slipping of the strata, is a matter of speculation, although the latter hypothesis seems the more probable. Assuming the latter case, the conduits which connected the present mineral-bearing strata with the source of the copper solutions, must have been numerous and widely distributed, as it is hardly possible that the mineralization could have spread over such a wide area from any single source of supply. Directly bearing upon this latter consideration, it may be stated as probable that the copper noticed in the Plomosas formation at Coyamito and Las Plomosas, has been derived from the same source and deposited at the same time as that of the Las Vigas formation.

CUCHILLO FORMATION.

What is undoubtedly the best section of this formation to be seen, is near Cuchillo Parado, on the road from the river to the Aurora mine, where the formation follows a depression in the Cuchillo Parado range. This range is formed by two parallel ridges, the westernmost of which constitutes the outcrop of the Las Vigas sandstones; the other forming the summit of the range, and consisting of the Aurora limestones. Between these two ridges and running throughout the entire length of the range, a considerable depression exists, which is occupied by the beds of the Cuchillo formation, including a thickness of about 2000 ft. The lower 1500 ft. of the formation is an almost pure gypsum, which at the surface breaks into a white sugary mass. A few thin beds of limestone course through the centre of the gypsum, showing quantities of fossil shells. The summit of the formation consists of alternate beds of gypsum and limestone, the latter becoming thicker as they approach the top, gradually passing into the massive limestones of the Aurora formation. At Chorreras

the Cuchillo formation consists almost entirely of clays, gypsum being practically absent. South from Rancho Viejo the ravines which cut through the mesas expose the same formation, consisting here of gypsum and clays, about equally distributed.

At Cuchillo Parado the lower part of the Cuchillo formation contains salt, which leaches out and is carried to the river, where the evaporation of pools often leaves crusts 2 in. thick. The exploitation of salt at this place was at one time an industry that furnished employment for several hundred people, but since the advent of the railroads the salt business has dwindled to almost nothing. Four miles south of the Santa Cristina mine, the Cuchillo formation has been broken through by an intrusion of granite; the clays having been converted into slates and the limestones into marble. These rocks being harder than the surrounding formation rise several hundred feet, in sharp contrast to the continuation of the beds east and west. To the west of the intrusion, a number of small veins have been formed in the metamorphic rocks, in which extremely rich bunches of lead-silver ores have been found near the surface, generally, however, changing into low-grade galena and blende as depth is attained. Perhaps a resource of greater value than either of the above mentioned minerals, is the great quantity of gypsum at Cuchillo Parado, which may become valuable as soon as the opening of railroads affords cheaper transportation.

AURORA FORMATION.

The name of Aurora formation was adopted on account of the magnificent exposure of these rocks near the Aurora mine in the Cuchillo Parado range of which it forms the culminating ridge. The formation as seen at the Aurora mine dips steeply to the east, becoming flatter as it is followed south to the edge of the Chilicote plain, where it then becomes flat and constitutes the bedrock of the plain. West of the Chilicote plain, the formation appears in the Chorreras range, dipping about 50° to the southwest. From here the limestones swing around to the north, crossing the Conchos river at Soldado and continue northward, forming the Sierra del Morrion and the hills around the Hormigas ranch. The outcrop in the Sierra del Morrion is practically vertical, the beds flattening slightly at the base of the mountains, dipping under the valley of Dolores to the west, and rising farther west to form the Sierra de Santa Eulalia, in which occur the famous mineral deposits. North of the Santa Eulalia range the relations of the limestones are rather obscure, but they are seen again north of Aldama, where they rise in the Sierra de La Peña Blanca, outcropping in a bold escarpment facing the east. Dipping to the westward at La Peña Blanca, the formation re-appears in the vicinity of Terrazas and constitutes the matrix of the lead and copper deposits of that camp. West of Santa Eulalia and Terrazas, the limestones almost entirely disappear under the eruptive rocks, and are only seen at infrequent intervals, where the combined forces of upheaval and erosion bring limited areas to the surface. One of these small areas is exemplified in the camp of Minillas, 10 miles northwest of the city of Chihuahua, where the limestone fissures contain lead-silver ores. On the west side of the valley of Cuchillo

Parado, the limestones dip into the San Pedro mountains, and rise again farther west near Las Vigas, the syncline being occupied by the valley of San Pedro. North of Las Vigas, the Coyame mountains are built up of this formation, which also contains great caves, said to rival those in Kentucky. The formation is nearly pure limestone, in thick layers; the entire thickness of the beds varying from 600 to 1500 ft., thicker in the western part of the region than in the eastern. At a few points, notably in the Chorreras range, numerous nodules of flint and iron ore were observed. Fossils are plentiful, but generally so firmly imbedded in the limestone matrix that it is difficult to obtain good specimens. A few fragments of ammonites were found near the base of the beds at Chorreras and several specimens of echinoids at Cuchillo Parado; the majority of fossil organism, however, are bivalves. This formation is probably identical with the Edwards limestone of the Texas Lower Cretaceous, as suggested by Robert T. Hill in articles on Santa Eulalia and Sierra Almoloya.

The Aurora formation contains the most important mineral deposits found in the entire region. Santa

clearly shown at the head of the gulch near the Vergara shaft, where the edges of several hundred feet of limestones have been uncovered by the erosion of the tuffs, showing the existence of an ancient hollow. The limestone must have subsisted for a long time as a land surface, the hollows now filled with eruptive material representing ancient water courses, the debris of which may be seen in the profusion of water-worn limestone boulders that lie on the limestone surface of the San Antonio Chico and other claims in that locality. Over this surface, volcanic outbursts spread an enormous cap of fragmental material filling the depressions and covering the limestones until the later beds of tuff show a uniform bedding independ-

Aurora Mine, and Cuchillo Gypsum.

Eulalia, Naica, Sierra Almoloya, Terrazas, Minillas, and Cuchillo Parado; all lead-silver producers, with some zinc; Jimenez and Terrazas, producing copper and silver, are all contained within these rocks. So much has been written regarding the mineral deposits of Santa Eulalia, and the opportunities afforded the writer in that locality were so limited, that no attempt will be made to enlarge on what has already been so well described. Having occasion, however, to wander over a good part of the camp for the purpose of determining the boundaries of several mining claims, the opportunity was improved to the extent of making an approximate sketch of the surface geology, which is herewith submitted. The Sierra Santa Eulalia lies near the eastern edge of the territory deluged by the igneous material which practically covers the country from this line westward to the western flank of the Sierra Madre. The east side of the Santa Eulalia range shows an appreciable thinning of the eruptive rocks to an edge and they disappear a few miles east of the range. It is observable also that the underlying rock is limestone, the surface of which, prior to the effusion of eruptive material, was extensively eroded, although the bedding remained practically horizontal. This is

Las Vigas Formation, Justicia Mine.

ent of the former topography. At the Picacho Robinson and the Cerro de la Campana, the tuffs are probably over a thousand feet in thickness, the greater part of which, however, in the gulch near Santa Eulalia village, has been removed by erosion. A flow of lava 20 to 50 ft. thick then covered the tuffs, this lava showing as a fringe of massive rock running around the hills to the north and south of the gulch of Santa Eulalia. On the top of the massive rock tuffs were again deposited constituting the highest formation in the district, most of which has been eroded.

During the period of eruptive activity, eastern Chihuahua consisted of a uniform plain surface, sloping gently toward the east, broken at intervals by local eruptions of igneous material, such as that of Sierra Rica. Subsequent to this ensued the folding which formed the Santa Eulalia and other parallel ranges. The same forces that elevated the district contributed to the formation of the ore deposits; the activity of the ore-forming elements probably having their inception with the first orogenic movement. The elevation of the range exposed it again to the ravages of the elements, which have disintegrated and swept away a large part of the overlying igneous

rocks, again laying bare the limestone, and carving out new canyons, often a thousand feet in depth.

At Terrazas, 25 miles north of the city of Chihuahua, the same formation encloses deposits of copper and silver-bearing lead. An intrusion of eruptive rock near the centre of the mineralized area, divides it into two distinctive portions, the southernmost of which contains only copper-silver ores, while that on the north produces only those of lead-silver, the copper and lead being nowhere associated within the district. The two parts of the district also differ from each other, in the fact that the copper mines are dry, while the lead mines are extremely wet. At one of the latter mines, at the time of my visit, it was impossible to make headway against the water with a pump throwing 1500 gal. per minute from a depth of only about 200 ft. The ore being soft, the miners were provided with extra long shovels, working with the water up to their chins and reaching as deep as possible after the ore. Diving suits were not provided, consequently production had to stop until the mine could be equipped with more effective pumping appliance. The copper ores, consisting of carbonates and oxides, are reduced on the spot. The lead ores were shipped to Torreon and El Paso. The ores consist of cave-fillings and metasomatic replacements in the limestone. In the eastern part of the region, near Cuchillo Parado, the Aurora mine is found in the same formation. The deposit follows approximately the bedding of the limestones, being seen to cut diagonally across some of the layers near the surface. Limited in its lateral extent, as far as could be seen, the Aurora deposit occupies a cavity which might have been the conduit of a hot spring. The outcrop is mainly iron oxide, which changes into a silicious lead carbonate within a few feet of the surface. The carbonate becomes purer as the deposit is followed into the ground, the lower workings at the time of my visit, showing ore 19 ft. wide, that averaged 40% lead with 4 oz. silver per ton. A striking feature of the deposit was the occurrence of pockets of wulfenite along the foot-wall containing from a hundred pounds to a ton of the mineral, the greater part of which consisted of beautiful crystal aggregations. In sinking a winze 160 ft., about 25 tons of this mineral had been extracted. The development of this district is retarded by difficulties of transportation; the completion of the Kansas City, Mexico & Orient, however, will bring the railroad line within 30 miles of the district and enable the mines to be operated at a profit.

Before dismissing the subject of the ore deposits of the Aurora formation, mention should be made of the influence of the Chorreras granite at its contact with the limestone. This intrusion, which has been mentioned as interrupting the Cuchillo formation, came up directly under the Aurora limestones, the contact between these and the granite showing for a distance of about two miles. The mineralization on the line of contact was represented by bodies of almost pure crystallized hematite. One such mass was over 400 ft. in length by 30 in width. The limestone within a distance of about 300 ft. of the granite has been metamorphosed into marbles of different shades of color, while the contact displays the usual

phenomena of green and brown garnet with more or less epidote. Amphibole of the variety called 'mountain leather', is also found in the vicinity, and has been turned to practical use by a Mexican mine-owner nearby for the lining of a primitive smelting furnace, which is still being used in the reduction of silver ores.

A fact not generally recognized is that all the important springs of water, wherever found in eastern Chihuahua, break out of the Aurora limestones. The oases of Coyame and Chorreras are fed from these sources, and the lesser springs of Hormigas, Chupadero, and others are in the same formation. Most of these springs exhibit a steady flow independent of the change of seasons. This suggests the possibility of reclaiming parts of the region now uninhabitable, by the development of artesian water. The Chilicote plain, for instance, toward which the limestone dips on all sides, might, instead of being a synonym for drought and starvation, be made to blossom, if the indicated artesian water should be developed. While the limestones, however, furnish channels and reservoirs for the circulation and impounding of water, their cavernous nature in other cases has drained the formation, leaving it almost dry. This is exemplified in the Potosí mine at Santa Eulalia, where shafts and bore-holes have penetrated to a depth of 2100 ft. without finding water. The reverse condition is found at Terrazas, where at a depth of 200 ft. it was practically impossible to exhaust the water.

OJINAGA FORMATION.

This includes the latest sedimentaries of the region, and is limited to the area of the Ojinaga basin, the soft character of the rocks being responsible for the modified topography of the basin, as compared with the outcrops of the surrounding formations, which rise in rugged mountain forms. Comprehending at least 2000 ft. of beds of different character, this formation probably includes the Washita division of the Lower Cretaceous, together with later beds, which may belong to the Upper Cretaceous. The marked unconformability which is generally understood to exist between the Upper and Lower Cretaceous was nowhere observed. Detailed study of these beds will no doubt succeed in connecting them with known formations lying to the northeast. The base of the Ojinaga beds, lying directly on the Aurora formation, is composed of thin-bedded gray limestones, which pass into a succession of shales having a total thickness of about 700 ft. Succeeding the shales, is a sandstone forming a prominent ridge and nearly a hundred feet thick. It contains fossil wood and other fragments of plant remains. The material between this sandstone and the summit of the beds consists of about a thousand feet of alternating clays and sandstones, the latter in thin beds, and not to be confounded with the massive one which lies near the centre of the series. The clays at two distinct horizons were seen to contain large fossil bones. A thin layer of sandstone lying 250 ft. above the massive sandstone, contains an abundance of small shells resembling *Turritella*. About 400 ft. higher in the series, a layer of clay 20 ft. thick was found, which contained numerous limestone nodules, in some places almost entirely made up of shells of *Exogyra*.

Fifty feet above this shell-layer another bed of clay showed numerous ammonites and nautili, many being extremely good specimens. This series of beds has attracted attention during the last three years as a possible source of oil, drilling for which is in progress at the present time. Cement materials occur in abundance within the formation. A slight amount of prospecting has been done for coal, but the largest seam found so far is less than a foot in thickness.

CONCHOS GRAVELS.

Occupying areas much greater than those indicated on the map, and representing accumulations of débris resulting from the erosion of the surrounding country, these gravels were carried into the lakes and there subjected to sorting and re-distribution, the gravels being found in fairly uniform beds, in which the boulders seldom exceed a foot in diameter. Calcareous waters percolating through the gravels have cemented them into a material resistant to erosion, as shown by the banks of the Conchos river,

also forming the hills around the Guadalupe placer. At Santa Eulalia the Aurora limestone has been covered with a considerable thickness of tuffs, as described in a former paragraph. Dikes of eruptive rock are common in the eastern and western part of the region, but in the central part are only seen in the Santo Domingo range. They occur in the Boquilla as an andesitic intrusion over 400 ft. thick, and continuing northward in the shape of a dike for nearly five miles. This andesite is in marked contrast with the dike-rocks near the Rio Grande, which are uniformly basaltic, and those of the western part, which are dacites or rhyolites. The Cerro del Coronal and Nombre de Dios near the city of Chihuahua are mainly composed of a thick sheet of dacite dipping to the west. A thin sheet of this material may be seen interbedded with the fragmental rocks in the hills overlooking Santa Eulalia, probably representing the edge of the lava flows eastward. The southern extension of the Santa Eulalia range is entirely

Santo Domingo Placer, Conchos Gravels.

where abrupt escarpments, nearly 200 ft. in height, consist entirely of the cemented gravel. Near the village of Santo Domingo, at a point where the cemented gravels have been disintegrated, small placers have been worked by the natives for a long time; probably for the last hundred years. A few years ago an American company subscribed a large capital for the systematic exploitation of the gravel, establishing a powerful pumping plant in connection with a steam-shovel for handling the material on a large scale. The steam-shovel, however, was insufficient to cope with the cemented gravel, and the enterprise has lain idle for some time, but is expected to start again on an area of disintegrated material that has been proved by late prospecting.

Eruptive rocks are of minor importance in the region of eastern Chihuahua, and are not found to any great extent until the line of the Mexican Central railway is approached, where the outlying edge of the Sierra province is reached. Near Hormigas, directly west of the ranch house, a line of low hills between Hormigas and the Aldama plain is composed of andesitic tuff-breccia, the same character of rocks

composed of massive eruptives, mostly dacite. Near the Rio Grande, numerous dikes of basalt, which can be traced for miles, break through the sedimentaries. About five miles northeast of the Nogal ranch a basaltic cone rises through the Ojinaga beds, the latter dipping away in all directions from the cone.

In striking contrast to all other eruptives of the region, the small intrusion of granite on the Chorreras ranch is interesting. This has been spoken of before in connection with its effect on the Cuchillo and Aurora formations; the sedimentary rocks having been metamorphosed to a considerable distance from the granite. The granitic facies is best observed near the centre of the mass, the structure becoming porphyritic as the edge is approached. The few small veins of silver-bearing galena west of the granite area, and the bodies of iron ore lying between the granite and the marble of the Aurora beds, doubtless owe their origin to this intrusion.

Concrete piles cost from 75c. to \$1.50 per lineal foot; the steel encased variety being considerably more expensive.

BLASTING DEEP HOLES.

Written for the MINING AND SCIENTIFIC PRESS
By O. H. PACKER.

There are many cases where it is more advantageous and less expensive to drill deep holes and blast with large charges of powder than to drill and blast a comparatively larger number of shallow holes. Theoretically, the amount of rock broken is in proportion to the cube of the depth of the hole, and the amount of powder used is in proportion to the square of the depth. For example, a 12-ft. hole would require $4^2=16$ times as much powder as a 3-ft. hole, but it would break $4^3=64$ times as much ground. That is, the 12-ft. hole would be about three times as efficient as three 3-ft. holes. Of course, theoretical results are seldom reached in practice, but more work can be done with deep than with shallow holes in any case, all expenses considered. If a hole be drilled too deep, however, enough powder can not be charged in it for proper blasting. In such a case the hole is only 'sprung'.

Deep-hole blasting is especially advantageous in making railroad cuts, or in grading for buildings, piers, and the like. The method to be pursued in drilling and blasting deep holes will depend upon the nature of the rock, the depth of the holes, and the number of holes to be drilled. When a large amount of rock is to be removed, either power-driven churn-drills or common 'Burleigh' drills will be most economical. If only a small amount of work is to be done, especially in soft rock, hand churn-drilling will be found most economical. The latter can often be used where the ground is too rough to move a power-rig. In any case, except where a power churn-drill is used, there is not enough room at the bottom of a deep hole for the required amount of powder, making it necessary to 'spring' the hole. To do this, proceed as follows: drop in the hole from three to five sticks of dynamite, tamping each stick with a wooden tamping-rod. Mark the tamping-rod to indicate the distance from the top of the charge to the surface. The primer, with a 2 to 3-ft. lighted fuse is dropped in. Water is usually the best tamping when springing holes, though clay may be used, especially with the last springing charge. All rock is capable of more or less compression, therefore, the detonation of the dynamite produces a cavity or pocket at the bottom of the hole by compressing the surrounding rock.

Unless the rock be soft, or the hole shallow, additional springing will be required to make the cavity at the bottom large enough to contain the charge for blasting. Deep holes in hard rock require 'springing' three or four times, and sometimes as many as 80 sticks of dynamite are used in the last 'springing' charge. The amount and grade of dynamite to be used in 'springing' and in blasting must be ascertained by trial. Experience is a good teacher, but it is advisable for even the experienced workman to experiment with different grades of dynamite every time a new piece of work is begun. In soft rock 'springing' is done with a low grade of dynamite. In hard rock the strongest grade is used.

The blasting is usually done with black powder except in wet ground, when a low grade of dynamite is better. Dynamite is suitable for 'springing' because the entire charge detonates at practically the same instant, thus shattering the rock in the immediate vicinity of the charge. Black powder is suitable for blasting deep holes because it is slow in action and gives time for its force to be transmitted a greater distance from the charge than dynamite. Some dynamite is made that contains only 25% nitroglycerine, and is almost equivalent to black powder in its action. This low-grade dynamite is, therefore, suitable for use, in place of black powder in wet holes. If the holes be drilled with a power churn-drill, 'springing' will not be necessary, as the holes are large enough to hold the charge.

In any case more effective blasting can be done by using an electric blasting-machine, so as to fire a number of holes at the same time. A blasting machine is simply a small dynamo for generating electricity. It is light, and may easily be carried from place to place in the hand. Just before connecting up the machine for a blast it is advisable to 'short circuit' it by connecting its positive and negative poles with a piece of copper wire so as to discharge any residual charge that might be in the machine. Such a residual charge might set off a few holes and thus necessitate wiring up the remaining holes again. Such a premature blast might also injure or kill some of the workmen. Use a strong blasting machine, and never try to blast more holes than the machine is designed to fire. Powder loaders, consisting of a funnel and a long stem, may be used to good advantage in loading with black powder. When starting a hole through gravel, or any kind of ground that has a tendency to cave, drop clay into the hole at regular intervals during the drilling to form a clay wall or casing around the hole.

The life of almost any wood can at least be doubled by thorough impregnation with creosote or zinc chloride. This means a great saving in the original cost of the timbers and in the labor of replacing them. Cheap woods when well treated are improved so as to possess many qualities of the valuable and naturally durable kinds, and will last longer than those which are naturally durable but untreated. Thus cottonwood, willow, spruce, lodgepole pine, or jack pine can be used in place of cedar for posts; birch, hemlock, or tamarack in place of oak for ties; lodgepole pine in place of cedar for poles. In every case the treated substitute will last longer than the wood commonly used, and will cost less. The Bunker Hill & Sullivan Mining & Concentrating Co., of Kellogg, Idaho, and the Hercules Mining Co., of Burke, Idaho, last year obtained the assistance of the Forest Service in designing and building treating plants. The Forest Service furnished an engineer in wood preservation to take charge of the plants until employees of the companies had become familiar with the work, the companies paying the expenses. The plants are now being run by the companies themselves. Anyone so desiring can obtain similar co-operation by application to the District Foresters.

ACCURACY IN ASSAYS AND ANALYSES.

Written for the MINING AND SCIENTIFIC PRESS

By JAMES W. HOWSON.

The degree of accuracy which must be attained in assaying and analytical work in order to secure satisfactory results is difficult to state definitely. Much will depend upon the value of the material to be assayed or upon the importance of the assay to the work in hand. There are many minor considerations involved, such as the thoroughness and correctness of taking the sample, the composition of the sample itself, the quantity of the element which is to be determined, the methods employed in the analysis, etc. Generally in analytical work on ores and similar products, duplicates should check within 0.20 or 0.30%. In volumetric work, since the difference of a drop of the standard solution makes a considerable difference in the results, unless the solution be very weak, it will frequently happen that the duplicates check exactly. The following table contains results in duplicate of most of the elements usually determined in ore analyses. Unless otherwise stated the material examined was an ore.

ASSAYED FOR ANTIMONY (Sb).

| Sample. | Per cent. |
|---------|-------------------|
| *1..... | 0.18—0.36 |
| *2..... | 0.72—0.90 |
| †3..... | 41.88—41.64—41.76 |
| 4..... | 4.74—4.82 |
| †5..... | 38.40—38.88 |
| 6..... | 9.96—9.70 |
| 7..... | 17.52—17.64 |
| †8..... | 27.84—28.20 |

*Determined volumetrically with standard iodine solution, fusing in the case of oxidized ores (cervantite).

†Stibnite.

‡Cervantite.

ASSAYED FOR ARSENIC (As).

| Sample. | Per cent. |
|---------|-----------|
| 1..... | 2.72—3.02 |
| 2..... | 2.66—2.56 |

Determined volumetrically with ammonium thiocyanate solution.

ASSAYED FOR BISMUTH (Bi).

| Sample. | Per cent. |
|---------|-------------|
| 1..... | 0.34—0.36 |
| 2..... | 47.28—47.78 |

Precipitated as carbonate and ignited to the oxide.

ASSAYED FOR CHROMIUM (Cr).

| Sample. | Per cent. |
|---------|-------------|
| 1..... | 27.10—27.54 |

Chromite fused with sodium peroxide in a nickel crucible.

ASSAYED FOR COPPER (Cu).

| Sample. | Per cent. |
|----------|-------------|
| *1..... | 0.17—0.83 |
| *2..... | 3.52—3.50 |
| *3..... | 14.25—14.21 |
| *4..... | 9.57—9.55 |
| †5..... | 5.38—5.38 |
| †6..... | 1.33—1.39 |
| †7..... | 1.88—1.88 |
| †8..... | 0.64—0.58 |
| †9..... | 19.71—19.84 |
| †10..... | 2.89—3.79 |
| 11..... | 3.53—3.54 |
| †12..... | 3.00—3.02 |
| 13..... | 1.90—1.85 |

*Iodide method.

†Cyanide method. A difference between duplicates of 0.20% is not to be passed under ordinary circumstances.

‡Electrolytic method.

ASSAYED FOR IRON (Fe).

| Sample. | Per cent. |
|---------|-------------|
| *1..... | 25.70—25.90 |
| *2..... | 22.59—22.74 |
| *3..... | 3.83—3.83 |
| *4..... | 20.08—20.08 |
| *5..... | 38.37—38.47 |
| †6..... | 47.53—47.32 |
| †7..... | 15.71—15.50 |

*Volumetric bichromate and permanganate methods.

†Slags.

ASSAYED FOR LEAD (Pb).

| Sample. | Per cent. |
|---------|-------------|
| 1..... | 45.10—44.80 |
| 2..... | 28.56—28.50 |
| 3..... | 7.85—7.65 |
| 4..... | 6.85—7.05 |
| 5..... | 9.00—9.10 |
| 6..... | 66.80—66.30 |
| 7..... | 16.38—16.48 |

Wet ammonium molybdate assays.

ASSAYED FOR LIME (CaO).

| Sample. | Per cent. |
|---------|-------------|
| 1..... | 2.99—3.04 |
| 2..... | 38.67—38.97 |
| 3..... | 51.35—51.45 |

Volumetric permanganate titration.

ASSAYED FOR MOLYBDENUM (Mo).

| Sample. | Per cent. |
|---------|-----------|
| 1..... | 2.97—2.54 |

Volumetrically with lead acetate solution.

ASSAYED FOR MANGANESE (Mn).

| Sample. | Per cent. |
|---------|-------------|
| 1..... | 54.40—54.76 |
| 2..... | 14.34—14.31 |
| 3..... | 5.21—5.14 |

Permanganate titration.

ASSAYED FOR MERCURY (Hg).

| Sample. | Per cent. |
|---------|----------------|
| 1..... | 0.11—0.10—0.08 |
| 2..... | 0.60—0.55—0.53 |
| 3..... | 0.04—0.06 |
| 4..... | 32.60—32.80 |
| 5..... | 27.05—27.60 |
| 6..... | 29.80—29.80 |
| 7..... | 36.40—36.60 |
| 8..... | 2.44—2.39 |

Eschka's method, using Whitton's apparatus. On low-grade mercury results should check to within a few hundredths of one per cent.

ASSAYED FOR SILICA (SiO₂).

| Sample. | Per cent. |
|---------|-------------|
| *1..... | 74.80—75.60 |
| *2..... | 6.30—6.30 |
| †3..... | 36.80—36.70 |
| †4..... | 27.80—28.00 |
| †5..... | 67.50—67.06 |
| †6..... | 7.00—7.02 |

*Insoluble gangue.

†Slags.

‡Fused.

ASSAYED FOR SULPHUR (S).

| Sample. | Per cent. |
|---------|-------------|
| 1..... | 45.30—44.95 |
| 2..... | 6.30—6.30 |

ASSAYED FOR ZINC (Zn).

| Sample. | Per cent. |
|---------|-------------|
| 1..... | 44.10—44.50 |
| 2..... | 15.14—15.00 |
| 3..... | 1.17—1.22 |
| 4..... | 21.35—21.40 |
| 5..... | 4.50—4.50 |
| 6..... | 31.45—31.50 |
| 7..... | 8.89—8.94 |

A. H. Low's method.

| ASSAYED FOR TELLURIUM (Te). | |
|--|------------|
| Sample. | Per cent. |
| 1..... | 2.08— 2.42 |
| Precipitated gold with FeSO ₄ , and tellurium in the filtrate with sulphurous acid. | |

The analyses which follow illustrate partial or complete analyses, in which the separation of the elements play, as a rule, a more important part than in simple determinations. It will be seen that, except in the more complicated separations, duplicate analyses agree quite as closely as in single determinations, that is, usually within 0.20 or 0.30%. Unless otherwise noted the lime, iron, and lead were determined volumetrically, and the alumina by difference.

| GYPSUM. | |
|---|-------------|
| Assayed for | Per cent. |
| Limestone (CaO) | 33.42—33.27 |
| Sulphuric acid (SO ₃) | 47.26—47.26 |
| Calculating the lime to CaSO ₄ .H ₂ O gives 91.68% gypsum. | |
| Calculating the sulphuric acid to CaSO ₄ .H ₂ O gives 90.97% gypsum. This affords a good check to the work. | |

| LIMESTONE. | |
|--|-------------|
| Assayed for | Per cent. |
| Insoluble gangue | 5.64— 5.64 |
| Ferric oxide (Fe ₂ O ₃) | 0.29— 0.29 |
| Alumina (Al ₂ O ₃) | 0.23— 0.23 |
| Lime (CaO) | 39.65—39.50 |
| Magnesia (MgO) | 10.44—10.87 |

| LIMESTONE. | |
|---|--------------|
| Assayed for | Per cent. |
| Silica (SiO ₂) | 7.70— 7.40 |
| Ferrous carbonate (FeCO ₃) | 3.09— 3.28 |
| Alumina (Al ₂ O ₃) | 0.66— 0.22 |
| Calcium carbonate (CaCO ₃) | 88.48—88.39 |
| Magnesium carbonate (MgCO ₃) .. | 0.38— 0.38 |
| | 100.31—99.67 |

| LEAD ORE. | |
|------------------------|-----------------|
| Assayed for | Per cent. |
| Insoluble gangue | 1.52— 1.70 |
| Iron (Fe) | 0.30— 0.20—0.20 |
| Zinc (Zn) | 10.47—10.57 |
| Lead (Pb) | 69.12—69.32 |
| Sulphur (S) | 16.45—16.37 |

| COPPER MATTE. | |
|----------------------------------|-------------|
| Assayed for | Per cent. |
| Silica (SiO ₂) | 1.54— 1.80 |
| Lead (Pb) | 1.47 |
| Copper (Cu) | 52.00 |
| Iron (Fe) | 20.22—20.14 |
| Lime (CaO) | 0.25— 0.25 |
| Sulphur (S) | 21.80—21.94 |

| CLAY. | |
|--|-------------|
| Assayed for | Per cent. |
| Silica (SiO ₂) | 58.00—58.20 |
| Iron oxide (Fe ₂ O ₃) | 4.43— 4.43 |
| Alumina (Al ₂ O ₃) | 17.05—17.05 |
| Lime (CaO) | 1.93— 1.93 |
| Magnesia (MgO) | 1.45— 1.52 |
| Soda (Na ₂ O) | 2.02— 1.90 |
| Potash (K ₂ O) | 2.36— 2.60 |
| Loss on ignition | 13.40 |
| | 100.64 |

| MANGANESE ORE. | |
|--|-------------|
| Assayed for | Per cent. |
| Silica (SiO ₂) | 19.62—20.04 |
| Ferric oxide (Fe ₂ O ₃) | 4.39— 4.39 |
| Alumina (Al ₂ O ₃) | 3.34— 3.13 |
| Manganese dioxide (MnO ₂) | 66.47—65.60 |
| Manganese oxide (MnO) | 4.72— 4.78 |
| Lime (CaO) | 0.52— 0.52 |

| MANGANESE ORE. | |
|--|-------------|
| Assayed for | Per cent. |
| Silica (SiO ₂) | 2.56— 2.60 |
| Iron (Fe) | 0.96— 0.96 |
| *Alumina (Al ₂ O ₃) | 6.86— 6.94 |
| Manganese (Mn) | 42.38—42.38 |
| Baryta (BaO) | 12.73—13.38 |
| Lime (CaO) | 5.70— 5.90 |
| Strontia (SrO) | 10.93—11.50 |
| Carbon dioxide (CO ₂) | 4.00— 4.00 |

*Direct pp. as the phosphate.

Usually in careful analytical work it is customary to have the analyses, or at least a portion of them, checked. Where the analysts' duplicates check closely, and the work has been carefully done, it will be found that the results obtained by a second analyst generally agree closely with the results of the first, provided the accuracy of the methods used by both is well established. The checking of work serves several purposes. It guards against the inaccuracy of the inexperienced analyst, while the inexperienced man engaged in routine work is less liable to slur over the fine points of his analysis, or to make any dangerous short-cuts, if he knows that his work is likely to be checked. Where extreme accuracy is required the average of the results of several analysts is usually more reliable than any individual result. The following results illustrate what has been said above:

| COPPER MATTE. | |
|---------------------------------|-------------------------|
| Assayed for | Per cent |
| | Assayer A. Assayer B. |
| Copper (Cu) | 56.54—56.30—56.30 56.32 |
| Copper (Cu), original sample... | 50.24—49.93 } 50.60 |
| Copper (Cu), duplicate sample.. | 51.09—51.14 } |
| Average | 50.00 |

| MERCURY ORE. | |
|--------------------|---|
| Assayed for | Per cent |
| | Assayer A. Assayer B. Assayer C. Assayer D. |
| Mercury (Ag) | 3.62 3.65 5.5 3.71 |
| Mercury (Ag) | 0.27 0.28 0.3 0.36 |
| Mercury (Ag) | 1.375 1.37 *0.5 1.36 |
| Mercury (Ag) | 0.02 0.04 Trace. 0.06 |

*Erroneous.

Assayers A, B, and D used Eschka's method with silver foil; assayer C used the electrolytic method.

| CEMENT. | |
|--|-----------------------|
| Assayed for | Per cent |
| | Assayer A. Assayer B. |
| Insoluble (SiO ₂) | 21.36— 21.20 21.12 |
| Iron and aluminum oxides (Al ₂ O ₃ , Fe ₂ O ₃) | 10.90— 11.30 11.20 |
| Lime (CaO) | 61.42— 61.82 61.51 |
| Magnesia (MgO) | 1.85— 1.96 1.91 |
| Sulphuric acid (SO ₃) | 1.88— 1.81 1.64 |
| Loss on ignition | 1.00— 1.04 2.40 |
| Undetermined | 1.59— 0.87 0.22 |
| | 100.00—100.00 100.00 |

In the above analyses either Assayer A underheated in determining the loss on ignition, or Assayer B experienced some mechanical loss. Both analysts used the standard method of analysis as adopted by the American Society of Civil Engineers, with a few individual variations to hasten the work.

Though much has been written concerning the care which should be exercised in order to secure accuracy in chemical analysis and assaying, there is but little literature on the subject that states empirically the limits of error in the work, for the ex-

cellent reason that such limits vary, and as has been said before are difficult to state definitely. According to Ernest H. Simonds* the limit of error cannot be stated to be invariably a certain percentage of the amount of the metal present, because the accuracy varies greatly according to the material to be assayed. For silver bullion the fire-assay may be relied upon to within about two one-thousandths (0.2%) of the content, although greater accuracy may be obtained with a proof-centre, using silver 1000 fine, or United States coin silver (900 fine), where the silver bullion is approximately that fine. If a possible error of two one-thousandths is too great, the wet assay should be used. For gold bullion, assays should agree to within one-half of a thousandth (0.05%), and generally they do agree to within one four-thousandth (0.025%). The sur-charge found by means of a check of proof-gold is usually four to seven-tenths of a thousandth. The following table gives actual results obtained. Bars 1 and 2 are mill-gold or retorted amalgam, from the battery and plates of a California stamp-mill. Bars 3 and 4 are cyanide-bars, obtained by melting the gold-sludge formed by acid refining of the zinc-box precipitate in a cyanide plant; hence the base metal zinc is present. In bars 5 and 6, most of the base metal is lead. Bar 7 is base silver bullion from Mexico. The seller used the fire-assay, the buyer the humid-assay for silver.

| Bar. | Weight, | | Seller | | Buyer | |
|--------|---------|---------|--------|---------|--------|---------|
| | oz. | Sample. | gold. | silver. | gold | silver. |
| 1..... | 225 | Dips | 722.25 | 268 | 722½ | 265 |
| | | | 722.30 | 267 | ... | ... |

| | | | 0.04 | 314.76 | ... | ... |

For silver sulphide precipitates, an assayer's duplicate assays should agree closely, within 30 oz. per ton, or 0.1%, on account of the homogeneity of the pulp. By the uncorrected fire-assay, that is, neglecting the slag and cupellation-loss, the following results were obtained:

| Assayer. | Method. | Gold, | | Silver, | |
|----------|-----------|-------|--|---------------|--|
| | | oz. | | oz. | |
| A | Crucible | 29.90 | | 11,293 | |
| A | Scorifier | 30.00 | | 11,278-11,308 | |
| B | Scorifier | ... | | 11,323 | |

In copper mattes the material is perfectly homogeneous, and easy to sample, and hence it is easy to obtain duplicate assays from it agreeing closely. The following table gives the results on 'shipping matte' from three different furnaces in widely separated districts:

| —Seller— | | | —Buyer— | | | —Umpire— | | |
|----------|-------|-------|---------|-------|-------|----------|------|-------|
| Au, | Ag, | *Cu, | Au, | Ag, | Cu, | Au, | Ag, | Cu, |

*These copper analyses were made by myself by the iodide method.

†Used battery method, and evidently forgot to subtract the silver.

In 1, 2, 3, and 4 the buyer determined the gold and silver by scorification, and the copper by electrolysis; the seller used the crucible assay for the gold and silver, and the iodide method for the copper. In 5 both buyer and seller used the crucible assay for the gold and silver, and the iodide method for the copper. In 6, 7, and 8 the seller used the scorification method with re-scorification of the buttons for the gold and silver, and the buyer used the crucible method; both used the iodide method for the copper. In 1, 2, 3, and 4 the contract between buyer and seller provided that an umpire assay should be made provided the assays varied more than 0.25% for the copper, 1 oz. for the silver, and 0.05 oz. for the gold.

In pyritic concentrates umpire assays are not generally made unless the values given by two assayers vary more than 0.05 oz. gold per ton, provided that the value of the lot figured from the results of the two assayers differs by less than \$20, or provided the variation is less than 1% of the total value of the lot.

Silver-lead ore and concentrate, the easiest of materials to sample, give perfectly uniform results. In the following table, 1 and 2 are from Idaho, and 3 and 4 from Mexico:

| No. Sample. | —Seller— | | —Buyer— | |
|-------------------|----------|-------|---------|--------|
| | Ag, oz. | Pb, % | Ag, oz. | Pb, %. |
| 1 | 67.5 | 63.2 | 69.4 | 62.8 |
| 2 | 72.4 | 64.5 | 72.8 | 64.3 |
| 3 | 311.00 | 36.3 | 312.50 | 36.5 |
| 4 Original | 230.50 | 30.2 | | ... |
| 4 Duplicate | 239.30 | 31.1 | | ... |
| 4 Average | 234.90 | 30.65 | 235.50 | 30.75 |

In checking samples, results show that they are correct to within about 2% of the total amount of the metal present.

| COPPER MATTE. | | | |
|-----------------|---------|---------|-------|
| | Au, oz. | Ag, oz. | Cu, % |
| Original | 35.50 | 342.0 | 52.72 |
| Duplicate | 35.64 | 337.6 | 52.78 |

| PYRITIC CONCENTRATE. | | | |
|----------------------|---------|---------|---------|
| | Seller. | | Buyer. |
| | Au, oz. | Ag, oz. | Au, oz. |
| First sample | 7.07 | 27.50 | 7.17 |
| Re-sample | 7.29 | 28.05 | 7.16 |

| No. of samples. | Highest. | | Lowest. | | Average. | | Composite. | |
|-----------------|----------|---------|---------|---------|----------|---------|------------|---------|
| | Au, oz. | Ag, oz. | Au, oz. | Ag, oz. | Au, oz. | Ag, oz. | Au, oz. | Ag, oz. |
| 102 | 1.10 | 47.40 | 0.02 | 0.25 | 0.213 | 6.79 | 0.225 | 6.70 |
| 16 | 0.40 | | 0.09 | ... | 0.204 | ... | 0.21 | ... |

In checking ore tests the total value ought to foot up to within 2 or 3% of that given by the assay of the ore pulp.

Bromo-cyanidation is not at present employed in any important plants in the United States. The chemicals required can be obtained from leading supply houses, or can be made readily on the spot.

ACCURACY IN SURVEYING.

Written for the MINING AND SCIENTIFIC PRESS
By LEE FRASER.

An important phase in both surface and underground surveying, but with special reference to the latter, is that phase dealing with the required accuracy and proportionate error of the work. It will be presumed that a standard for accuracy has been established, and that it is only sufficiently good for the purpose. It is impossible to do work without error, and a full appreciation of the nature, relative size, and weight of such errors, together with an idea of the cost for decreasing them, is of the

utmost importance for the performance of the work with least labor, yet, at the same time, maintaining a degree of accuracy equal to the standard.

Perhaps one of the most common errors made by engineers, working to any certain standard of accuracy, namely, 1-5000, is the consideration they bestow upon the measurement of horizontal distances greatly in excess of what is required for the purposes of the survey. Upon consideration of the accompanying figure, together with the following table, the data required to regulate the survey for the best performance with reference to any standard may readily be secured.

| LIMITS OF ERROR. | | | | | |
|------------------|--------------------------------|--|--|--------------------|------------------------------|
| De- gree. | Vertical Displace- ment. | Decrement in Horizontal Displace- ment per 100. | Error in Measurement Plus or Minus. | Final Error. | |
| 1..... | 1.7452 | 0.015 | $\frac{1}{6666}$ | $\frac{1}{20,000}$ | $\frac{1}{10,000}$ 5000 |
| 2..... | 3.4900 | 0.061 | $\frac{1}{1639}$ | $\frac{1}{20,000}$ | $\frac{1}{1785.7}$ 1515.1 |
| 3..... | 5.2336 | 0.137 | $\frac{1}{730}$ | $\frac{1}{20,000}$ | $\frac{1}{757.5}$ 704.2 |

RADIUM ORE.

The discovery of radium ore in the United States is the object of a movement started by Thomas F. Walsh, of Colorado. Through the Vinson-Walsh research department of the Colorado State School of Mines at Golden, which is supported by Mr. Walsh, tests will be made of all samples of pitchblende free of cost, and the results will be regarded as confidential. To meet the preliminary cost of the undertaking, Mr. Walsh sent to Victor C. Alderson, president of the School of Mines, a check for \$5000. In his communication to Mr. Alderson, he makes the following appeal to the prospectors of Colorado and the United States: "Radium has never been produced in the United States. It comes from pitch-

blende, and is of most priceless value. Austria has a monopoly on this ore. Why should we not produce it in Colorado? The richest prize in the mining world is a vein of pitchblende ore. This rare ore is apt to be found in many mining districts of the State. In finding it you will be enriching yourself, placing your State in the front rank, and helping to open a new industry in mining. The undersigned trustingly appeals to his brother prospectors and mine operators to look for this mineral. He believes the doing so will bring great results." Mr. Alderson stated that to a limited extent the School is ready to furnish responsible persons samples of pitchblende to aid in familiarizing prospectors with its appearance.

Copper production in Russia has been steadily increasing, as is shown by figures furnished by Hunter Sharp, Consul General of the United States at Moscow. The production amounted to 10,306, 14,554, and 16,591 tons in 1906, 1907, and 1908, respectively. The production in the several districts in 1908 were as follows, in tons: Ural, 8429; Caucasus, 4780; Siberia and Kirgis, 2416; all other districts, 966. The consumption of copper in Russia in 1908 was as follows: Produced in the empire, 16,478 tons; imported, 4855 tons; total, 21,333 tons, less 113 tons exported.

The Prospector.

This department makes a charge of 25 cents to subscribers not in arrears and \$3 to non-subscribers for each determination. To ensure promptness in publication of the determinations, payment must be forwarded with specimens.

J. H. P., Golconda, Nevada; Gabbro.

A. B. C., Battle Mountain, Nevada: Black basalt containing some pyrite.

A. H. A., Rhyolite, Nevada: Black limestone intersected by veins of chalcedony and calcite.

M. D., of Yerington, Nevada: No. 1, pyrite and a little chalcopyrite; No. 2, feldspar-porphry; No. 3, pyrite; No. 4, yellow serpentine on limestone; No. 5, granite; No. 6, porphyrite; No. 7, syenite.

J. R. L., Dunsmuir, California: No. 1, the three specimens of this number are serpentine dike rocks and could be originally basalt or diabase; No. 2, quartzite; No. 3, a serpentine-feldspar-quartz rock, possibly an altered rhyolite or andesite.

J. H. T., Fallon, Nevada: No. 1, diabase; No. 2, metarhyolite; No. 3, quartz with galena, pyrite, and earthy limonite formed by the alteration of the pyrite; No. 4, altered andesitic rock; No. 5 and 6, metamorphic schistose rocks, perhaps changed andesite or rhyolite.

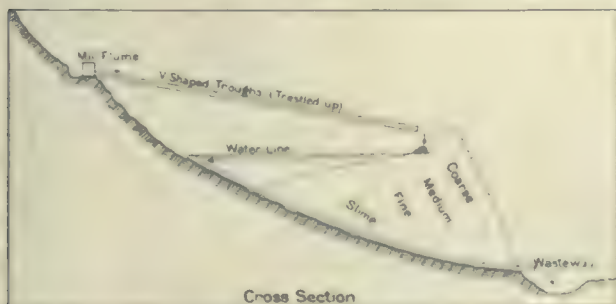

A. T., Auburn, California: No. 1, a mineralized hornblende-diorite containing pyrite and some chalcopyrite; colors are due to slight iridescent tarnish; taste may be due to alteration of the sulphides; No. 2, quartz with pyrite; No. 3, quartz with pyrite. The specimens are of no value.

IMPOUNDING MILL TAILING.

Written for the MINING AND SCIENTIFIC PRESS
By H. W. MACFARREN.

The impounding of mill tailing has usually one or more of three purposes in view: to restrain the tailing from reaching watercourses or places where not desired; to impound for future treatment; and to permit of pumping back part of the water for re-use in the mill.

For the pond, a convenient site is selected requiring the smallest length of bank building. A hill for one side is desirable. The flume conveying the tailing from the mill may be carried along the contour of the hill, and as high up as it is intended to eventually raise the pond. At the pond, gates in the flume should be spaced 20 ft. apart, and light V-shaped troughs, trestled up, carrying the pulp near the outer bank. The coarse sand naturally settles at this discharge point, while the slime flows back toward the hill-side of the pond where the wasteway is situated. The pond should be divided into two or more parts: after filling one, it is dried sufficiently to enable the bank to be raised by shoveling, while the other is being filled. As the bank is composed of

Building Up Tailing Pond.

coarse sand without slime as binder, cracks are liable to occur in freezing weather, resulting in bad breaks. The wasteway for the overflow water should be a three-plank flume, 6 in. square, built on the ground, and in the middle of the hill-side of each part; the height of the overflow is raised as necessary by nailing on 6-in. widths of plank. The mill-flume can be trestled along the outer bank of the pond and the V-shaped troughs dispensed with.

Where the tailing is being banked for cyanide, a system of filling should be used that will result in the sand and slime being well mixed instead of segregated apart. Four or more sets of inlets and outlets should be spaced about each section, and a change made daily or semi-daily to a new set. This will result, to some extent, in throwing a layer of sand on top of a bed of slime, into which the sand will sink. While the mixing will be imperfectly done, it will be sufficient to enable a resourceful cyanide man to easily leach the whole dump, instead of leaving a large quantity of slimy material behind as unleachable.

Where it is desired to return some of the water, the ponds can be constructed along the line first described; but it is better to build a de-watering plant in the lower end of the mill, where it can be easily reached by the men on duty and where a pump can be belted to motive power already in place. These

plants are not expensive. Distribute the pulp to some deep pulp-thickening tanks—the number depending on the quantity of pulp and the settling rate of the slime, having an annular overflow, and introducing pulp some distance below the surface of the overflow, so as to get the settling effect of a slowly ascending current. The tanks should have cone bottoms of 60° pitch and be fitted with large gate-valve discharges, by which the sludge is partly, but not completely, withdrawn at intervals. These settlers are satisfactory, giving a thick sludge, and requiring little labor or attention. If the wooden box-settler is used, it should be divided into compartments ending in these cones with gate-valve discharges.

A novel instance of mill-tailing put to agricultural purposes is found in a California camp. Some 30 years ago, the tailing from a large mill crushing a quartz ore containing much of the slate in which the orebody lay, after running in a creek for three miles,

Farm-Land Made From Tailing.

was caught and impounded to form a soil. The flat bottom of the creek had been cleaned bare by placer miners years before. A stone wall, 6 by 15 ft. high, was roughly laid up to keep the creek on one side, and as a bank to raise the proposed surface above possible high-water. This wall was about 2200 ft. long, and gave a strip of ground of that length and from 125 to 250 ft. wide, to be filled by the tailing. This filling was done in sections and required several years. The surface was well manured, and was found to make an excellent soil for growing vegetables and fruits, being preferred to the natural soil, and it has been actively worked to this day.

With this tailing-pond garden as a nucleus, the surrounding hill-sides were brought under cultivation as hay fields and orchards, and eventually the mountains about were called upon to support numbers of cattle. In this way there was developed a valuable piece of property and a highly remunerative business. The originators of this idea were Italians. Various propositions looking to the extraction of the gold still remaining in these sands have been made, but the owners are loath to risk losing the goose that lays the golden egg for them. A smaller farm has recently been constructed in the same manner higher up the stream, a part of which has been brought under cultivation, as seen in the accompanying illustration.

ELECTRICAL MINE-PUMPS IN EUROPE.

Written for the MINING AND SCIENTIFIC PRESS
By A. S. ATKINSON.

The application of electricity to the operation of colliery pumps on the continent of Europe has attained great success in the last decade, and the results are both on the side of high efficiency and profit, but in using pumps of large capacity for mine purposes, it has been found that much depends upon the adaptation of various types to particular purposes. In this respect the engineering profession has followed certain well-defined principles which are today recognized as of prime importance in the installation of any mine machinery.

There has been a tendency to reduce the high-speed pumps for high-lifts and to substitute a moderately high-speed type owing to the greater security from break-downs, valve-troubles, and delays. In all mine-pumping safety and reliability come before efficiency. The modern electric pump, as used mostly in European collieries, is a medium between the express pumps of large capacity run at 250 to 300 rev. per minute, and the old-fashioned slow-speed pumps of 50 to 80 rev. The most successful type installed are apparently those which make from 120 to 200 rev. per min., for besides moderate speed and high efficiency, there is a great gain in safety and reliability. The small pumps, of course, are operated at higher speed, especially where they are belt-driven. Electrically driven high-pressure pumps for mining purposes are of several types, such as the Sulzer and Rateau pumps, and their many variations. At the Victor-Rauxel colliery, in Westphalia, several of the former type have been in operation for some time, and their success is worthy of note. The centrifugal pumps are of high capacity, and work against a head of 1800 ft. They are placed at the pit-bottom, and are installed two in a series. Each pump has a capacity of 1500 gal. of water per minute against a head of 900 ft. These pumps are run day and night, and during the 5 years they have been in operation, there has hardly been a hitch. The uninterrupted working of the pumps, and their high efficiency, demonstrate the satisfactory results that may be obtained from electricity as motive power for mine-pumping. The plants have shown an average total efficiency of 59%, the pumps giving 75% and the motor itself 93.

Pumps of the Rateau type have been installed and kept in good working order for a number of years in the Carmaux colliery, France, and here, too, reliability and economy of operation have been obtained. One of these pumps has a capacity of 80 gal. of water per minute, working against a vertical head of 1350 ft., at a speed of 2900 rev. per min. This type of pump is considered better adapted to the pumping of smaller quantities of water against a greater head, and the Sulzer pump is best suited for large quantities and lower heads. The chief difference between these two types of European pumps and their many variations is in the manner of forcing the water out. In the Rateau type the water enters the passages of each impeller at the centre, and is then forced to a collecting-chamber by rotation. In the Sulzer pump and its modifications the water flows on the impel-

lers in an axial direction, and is then thrown out radially. Both types are operated by high-speed three-phase motors. These are best adapted to mine-pumping and are also the cheapest and most reliable. The motor can be worked up to an output of 100 hp. without a starting switch. The 3-phase motor adapted to mine-pumping is practically free from any danger of a break-down, and if direct driving be employed there are fewer parts to get out of order. Gearing and belts always increase the danger of interruptions and break-downs. In the collieries mentioned the motors are installed between the pumps, and are direct connected. They have centrifugal compensators that are made completely gas and water-tight, and they cut out the starting-resistance automatically.

A number of electrically operated pumps have also been in use in the South African mines, and their record of continuous operation is little short of marvelous. One of these pumps installed at a depth of 1500 ft. was operated without interruption for two years, and then the mine was abandoned for a year, during which time it became flooded. When operations were re-commenced, the pump which had been left there was cleaned and repaired, and it has run continuously ever since. Much of this success, however, depends upon the type of pump, and the carefulness with which the electrical and other equipment are installed. The pump-rooms in the European mines are built of stone or brick, and they are made as near as possible water and gas-tight. This practice is followed even in mines that are considered exempt from fire-damp. The brick or stone pumping-room must, however, be well ventilated and lighted, and if it serve as a distributing station for the whole colliery, the cables entering it can always be inspected and repaired without trouble. The long life of an electrically operated pump depends a good deal upon the care given to every part, and this cannot be done unless the pumping station and room are made light and clean.

Where there is always danger of fire-damp and floating gases the necessity of making the electrical equipment gas and air-tight is quite important. The switch-gear in particular must be tight against gas. If all the switch-gear be installed in a single room where workmen are not allowed to enter, the danger of accident is greatly reduced. A central telephone station installed in the pump-room, connecting with all parts of the mine, further improves the certainty of protection from long break-downs and accidents. The telephone station thus pays for itself in a short time, and so greatly facilitates operation in a large mine that it is almost invaluable. Electrical pumping in collieries makes the most flexible system yet devised, but, of course, where the mines are flooded the difficulties must be met in other ways. This is overcome in the European mines, equipped with electrically operated pumps, by using sinking-pumps which can work under water for any length of time. Nearly all of the collieries are equipped with auxiliary pumping apparatus, so that they can cope with an unexpected flood of water due to accidents at any time. If the pump-room be made water-proof up to at least three or four feet above the bottom level, the

spare pumps can be put into operation before any material flooding and damage follow. The sinking pumps are specially installed under conditions somewhat different from the stationary pumps. They have to be adapted to each particular mine in such a way that they can operate satisfactorily under excessive and unexpected flooding at short notice. Electricity lends itself to the operation of sinking pumps much more readily than steam, for in the latter case the cooling effects of the water act as condensers and retard the operation.

In Europe, where electrically driven pumps have been in operation in mines longer than in this country, the average efficiency has been found to reach about 65%. This is based upon the following allowances of efficiency of the different parts of the plant; engines, 88; dynamos, 93; cables, 97; motors, 90, and pumps, 86%. The express-pumps have the highest efficiency, reaching in some cases a total of 95%. Express-pumps of the most improved type average between 90 and 92. The centrifugal pumps have a lower efficiency than the other types, but this is partly compensated for by a higher motor-efficiency. This difference in the efficiency of the two types is more noticeable in those of small capacity, and in the larger pumps it gradually disappears until it becomes approximately the same.

The high-pressure centrifugal mine-pumps have found great favor in most of the European mines because of their wonderful simplicity, lightness, high-speed, and compact small dimensions. These are qualities which are most desirable in deep mines where the water-head must be kept down through continuous and interrupted pumping. The great flexibility of the cables enables the mine operators to use sinking pumps at almost any part of the mine on very short notice, and this has saved more than one mine from being flooded through some slight accident. On the other hand simplicity of operation and installation does not mean that the equipment can be carelessly designed and constructed. The construction must be of the best, and adapted to local needs. There is no place in mine operation where ignorance or oversight causes greater trouble than the installation of big centrifugal pumps. With the initial installation properly made, the repair and maintenance-cost is relatively light. With fair attention to the up-keep the danger of break-downs is practically eliminated. This has been fully demonstrated in the continental collieries where electric pumps have been employed for upward of 6 or 7 years. Other mines are being equipped with pumps similarly operated, so that it may be assumed that within a year or two the leading mines in Europe will have at least one or more sets of electrically operated pumps in use. The practice in Europe, for the most part, is to use motors with the 3-phase system, with the motor turning around a vertical axle, which is carefully balanced and protected from dripping water. Ball-bearings carry the weight of the rotating parts, and these are enclosed in a hood which also protects the starting device. The motor-shaft and pump-axle are in one piece. All the windings are extra-insulated, so that the cable and wires are not seriously affected by the dampness of the mine. The starting and stopping

device is placed on the pump, so that full control can be had within the shaft. This avoids delays which might prove serious if signals had to be made to the surface. All the switches and starting devices are enclosed in protectors that are both gas and water-tight.

The installation of an electric power-station in the European mines for driving pumps generally means the application of this power in time to the operation of other machinery. It is a simple matter when the plant is installed to use the power for driving fans and operating hoists and other equipments. At several of the French collieries the hoisting is done by electricity, and recently a producer-gas plant has been installed for generating the electricity. The producer-gas is made from the slack-coal at the colliery. Before the producer-gas plant was installed the waste heat from the coke-ovens was utilized for power. The producer-gas plant, however, has developed a distinct gain over the old method of using the waste gases. This work of equipping collieries with producer-gas plants for generating electricity, and then distributing the power as needed throughout the mines, is considered by most of the leading European mining engineers as the ideal method for the future. The slack-coal burnt in the producer-gas plant represents the cheapest fuel obtainable, and the high efficiency of producer-gas plants makes the economy unusually large. One deep mine in Germany has a plant of 1000 hp. which operates dynamos sufficient to supply the mine with all the power required for hoisting, driving fans and electric-pumps. In addition to this there is an auxiliary plant which furnishes lighting for the mine and the works above ground.

The depth of this mine is 590 ft., and the net load brought to the surface at one time averages 7400 lb. Formerly it took about 6.9 lb. of coal per actual horse-power expended in raising the coal to the surface. Since the producer-gas plant has been in operation, the average amount expended for each actual horse-power used is less than 2 lb. The cost of maintenance of the producer and the electrical equipment is also small, but the initial expense of installing was naturally considerable. It is estimated that within 5 years the saving will far more than compensate for the extra expense of the initial equipment. In this mine the current is taken to the winding-engine house at 5000 volts, 3-phase, and then transformed down to 200 volts and used in the motor. The pumps and ventilating fans receive their current over a separate cable, which is flexible enough to permit of wide variation in operation. The use of the producer-gas in coal mines is not exactly a novelty, but the performance is still in its first stages, and data concerning the actual cost of operation are not generally supplied. The installation in European mines is now progressing rapidly, and their usefulness and efficiency have been widely demonstrated.

On the advancing edge of the zone of combustion in a heap of pyrites exists a stratum of fused sulphur. It appears that to a certain extent dissociation of the base and the sulphur occurs before the sulphur is oxidized.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

INJURY TO MINER—INCOMPETENT SERVANT.

The owner of a mine was held liable for injuries to a miner from the negligence of another employee acting as hoisting engineer, where such engineer was incompetent and was hired as a fireman and was required to leave that work and act as engineer as occasion required during the night-shift when no regular engineer was present.

Layzell v. J. H. Somers Coal Co., (Mich.) 120 North-west. 996, Apr. '09.

LEASE OF MINES—CONSTRUCTION.

A written instrument granting the right to mine and remove the coal in a tract of land for a period of years, and to take the necessary, usual, or convenient means for working and taking away such coal created an estate for years in the land. And if the estate created was for more than five years it could only be assigned by deed or will. In any event the assignee of the lessee was liable to the lessor for the rent reserved in the lease if he covenanted or agreed to pay the same, or if privity of estate between him and the lessor be established, but not otherwise.

Comley v. Ford, (W. Va.) 64 Southeast. 447, March '09.

INJUNCTION TO PREVENT TAKING AND SELLING ORE.

Where it appeared from the decisions in prior litigation that a mining company would, in a pending action, probably recover a large judgment against another mining corporation for the value of ore extracted from mines owned by the complainant, a court was authorized to grant an injunction restraining the defendant company from extracting or selling any more ore from the mine, and where it was shown also that the defendant mining company would not have sufficient mining property remaining to satisfy the judgments that might be rendered.

Montana M. Co. v. St. Louis M. & M. Co. 186 Fed. 514, March '09.

DRILLING OIL WELLS—EXPERT EVIDENCE.

The art or mechanical skill of properly drilling oil wells through different strata, the character of the strata, the proper treatment of them, the appropriate tools best suited for them, the proper casings, cleaning the well, fishing for and extrication of broken casing and lost tools, and other incidents in the work are not within the knowledge of people generally, and all such matters come clearly within the rules of expert evidence.

Redd v. Carnahan, (W. Va.) 64 Southeast. 138, March '09.

INJURY TO MINER—LIABILITY FOR FAILURE TO KEEP MATERIAL.

Under a statute providing that the superintendent of a mine shall at all times keep on hand at the mine materials necessary to preserve the health and safety of the employees as ordered by the mine foreman, it was decided in an action for damages for injury to a miner that, unless it appeared that the mine foreman had made a proper requisition for the materials, and it had been refused, or that the owner or superintendent of the mine had failed to keep on hand the necessary materials, or supplies, the owner of the mine was not liable. To make the mine-owner liable for injuries caused by an explosion of gas, on the ground of negligence in failing to furnish proper material, it must be shown that such negligence was the cause of the injury.

Bisko v. Brasnel Coal Co., (Pa.) 72 Atlant. 504, Jan. '09.

OIL AND GAS LEASE—CONSTRUCTION.

A lease of land to explore for oil and gas, and if found, to produce them, was held to be merely the grant of a privilege to enter and prospect, and did not convey title to any oil or gas until found.

Gillespie v. Fulton Oil & Gas Co., (Ill.) 88 Northeast. 192, Apr. '09.

American Mining Congress.

The American Mining Congress will hold its twelfth annual session at Goldfield, Nevada, September 27 to October 2, 1909. A program is being arranged which will include a discussion of various matters pertaining to the welfare and progress of the mining industry, the aim being to give greater opportunity for practical discussion and consume less time in the reading of technical papers.

During the past year the Congress has had several committees at work conducting investigations, report of which will be made to this session. These reports will be open for discussion, and the committees reporting are as follows:

Committee on Vertical Side-Line Law. By George W. Riter, Salt Lake City, Utah, chairman.

Committee on Coal Tax Insurance Fund. By Samuel A. Taylor, Pittsburg, Pennsylvania, chairman.

Committee on General Revision of Mining Laws. By Walter R. Ingalls, New York City, chairman.

Committee on Standardization of Electrical Equipment. By Edward B. Rosa, Washington, D. C., chairman.

Committee on Prevention of Mine Accidents. By H. Foster Bain, San Francisco, California, chairman.

Committee on National Forest Service. By A. G. Brownlee, Denver, Colorado, chairman.

Committee on Alaskan Mining Laws. By J. L. Steele, Landlock, Alaska, chairman.

The silver question will be discussed with a view to devising means of bringing about a greater use of silver, and decreasing the rate of exchange between the United States and countries using a silver standard. Moreton Frewen, of London, England, James J. Hill, and John Hays Hammond have been invited to speak on this subject. Goldfield citizens are making elaborate arrangements for showing the district to the delegates, and the State of Nevada has appropriated \$5000 to pay the expenses of collecting and classifying a comprehensive display of the State's minerals, which is being installed at Goldfield. The Congress will consist of the regular members of the organization, and all duly appointed delegates, who have equal powers in all the deliberations of the open body. Mining men contemplating attendance should address the secretary, Walter A. Koch, at Denver, Colorado, for more complete information.

REPORTS recently issued by the U. S. Geological Survey include a preliminary paper on the Innoko district by A. G. Maddren gives the total gold production of the district for 1907 and 1908 at \$85,200, of which the season of 1908 is credited with \$72,100. Four claims have produced more than \$10,000 each in a single season. A report on the chromite industry in the United States by E. C. Harder has also been issued. Almost the entire production comes from Shasta and San Luis Obispo counties, California. The total production of coal in Alabama in 1908, as reported to E. W. Parker, was 11,604,593 short tons, having a spot value of \$14,647,891. The decrease in production over 1907 was 2,645,861 tons. The report of J. S. Diller on the production of asbestos in 1908 states that the United States leads all other countries of the world in the conversion of raw asbestos into manufactured products, although a very small percentage of the material used, less than 1%, is mined here. By far the larger part of it comes from Canada. It is gratifying, however, to note that the production of asbestos is on the increase in the United States and that the increases are in grades that are better than those previously produced. Other reports just issued by the Survey include one on 'Gypsum and Gypsum Products in 1908', by Ernest F. Burchard, and another on the 'Production of Talc and Soapstone in 1908', by J. S. Diller.

BUILDING of small tramway lines has been a feature of the development of the State of Sao Paulo in Brazil for many years, and such roads are still being constructed in many directions. The latest project of this kind is for a road 11 miles long near Sao Paulo, for which equipment is desired. The estimated cost is \$170,000. The projector of the line is Francisco H. de Mello, of Sao Paulo.

EDITORIAL.

RAILROAD transportation in Pullman cars is now open all the way from New York to Salina Cruz, the terminus of the Tehuantepec line on the western coast of Mexico. Thus travel to Central American points is greatly facilitated.

THE gross aggregate international trade of the world amounts to 30 billions of dollars annually. The United States contributed 14.4 per cent of the total foreign imports, and of the exports from other countries the United States takes 9.2 per cent.

OFFICIAL announcement by the War Department shows that a little more than 45 per cent of the total cube of excavation on the Panama Canal has been removed. The exact figures are 78,905,501 cubic yards taken out, and 95,761,094 remaining.

PIG-IRON is now being produced by the electric furnace at Heroult, Shasta county, California, and is being sold at the foundries in Redding in competition with Eastern iron, the present price at that point being \$25 per ton. It will soon invade the San Francisco market, and tend to give more stability to prices, the cost of casting iron at this point varying according to the ballast-requirements of vessels from the Atlantic cities or from China. The success of electric iron smelting will profoundly benefit industrial conditions on the Pacific Coast.

QUESTIONS of the rights of aliens in mineral lands are constantly arising. The tendency of most Governments is liberal in this matter, and the laws of the United States cannot be considered otherwise. Nevertheless the view of Congress has been that minerals on public lands constitute a resource held in trust for the benefit of citizens. Consequently an alien, whether he be an original locator, or whether he may have acquired ownership by purchase, is not accorded the right to obtain patent to a mining claim, and it is possible for the Government to institute proceedings to dispossess an alien locator. Except in the Territories, however, aliens may purchase and securely hold patented claims.

Closing of the Argo Smelter.

Announcement has been made that the Argo smelter of the Boston & Colorado Smelting Company will be closed next month, and that the company will liquidate. This will be noted with regret by technical men familiar with the history of smelting in the West. The plant was first built at Black Hawk in Gilpin county, Colorado, in 1867, but in 1878 it was removed

to Argo, near Denver. It was founded by Richard Pearce and Nathaniel P. Hill, and the company has always been noted no less for the high plane upon which its business was conducted than for the excellence of the technical performance of the plant. It was the first smelter which successfully treated the pyritic ores of Colorado, using copper for a base. In the early days it drew from Montana, the Black Hills, Colorado, New Mexico, and even from Arizona and Utah. The field has gradually narrowed as newer plants have been erected, and aggressive competitors have come to the fore. In the meantime the character of the ore shipped from Gilpin and Clear Creek counties has materially changed. Whereas formerly ore containing 15 per cent of copper was readily available, that now shipped direct to the furnaces is silicious, and seldom contains more than 3 to 4 per cent of that metal. Concentrates from these counties carry about 2 per cent of copper. Ores from the Black Hills are no longer largely smelted, and Utah and Arizona have their own plants. The Argo, it is announced, can no longer make a profit with the present plant under existing conditions. It is comforting to know that profits in the past have been large, and that the company closes a long and honorable career without having drifted into financial straits. Shortage of ore of suitable character is solely responsible. It is not a case of being driven out by a trust. While the Boston & Colorado Company has maintained its independence, it has worked cordially with the American Smelting & Refining Company since the latter was organized. The Chamberlin Dillingham Ore Sampling Company has bought ore for both companies under an arrangement whereby all ore of certain grades and character went to the Argo plant, while other ores were turned over to the larger company.

The passing of the Argo smelter marks an epoch in the history of smelting in the West. In its career it made possible the opening of many mines. The mining districts that its facilities made productive have developed smelting plants nearer home, and in the resulting competition of region against region Colorado is undoubtedly losing ground. While old plants are running and new ones are being built, the aggregate amount of ore being smelted in the State is declining. Modern mines, based on large tonnage of low-grade ore, necessitate smelting at the nearest centre at which flux, fuel, and water are available, and Montana, Utah, and Arizona have the lead.

The Pole and the Flag.

America has the honor of the greatest achievement of recent times in the field of exploration. "Stars and Stripes nailed to the pole"; such was the laconic message of the twentieth-century Harald Hardrade, who may be called in a modern sense the 'King of the Northmen'. Commander Robert E. Peary has won the pole in the way that all great things are done; by knowledge and persistence. Taught by experience, patiently exhausting years in strenuous effort, surveying ice-locked coasts on the frozen edge of the world—the Ginnungap beyond which lay the goal shrouded in mystery for centuries—Peary laid

his foundations well; he followed the 'good old maxim, "get ready first"; and he won. He has been twenty-three years doing it, and the world doubted that it would be done. But one brave woman never doubted, the woman who shared the arctic rigors with him in her earlier years, and spurred him on with faith and trust. It is beautiful to see the words which reveal the source of inspiration leading to triumph, in the message from Indian Harbor to "Jo" (Josephine Diebitsch Peary), "Have made good at last." We remember the youthful ardor of Commander Peary when he was but 34 years of age; he must hasten with his work, because men from the South could not stand the severity of the Arctic after 40; but he has had to struggle on far beyond the limit set in his youthful fervor, and he is 53 when he plants the flag on the pole. We give our praise to Peary, without discrediting the achievement of Dr. Frederick A. Cook. The world will suspend judgment, regretful to see the brilliancy of this exploit, so satisfying to national pride, clouded by a personal controversy. It would have been pleasanter if Peary had merely laughed and waited for further light. It evokes the funny man, who cannot help remarking on the high temperature generated by friction over the pole. Jules Verne in story placed a volcano on the axial point of the earth; and there has come in very truth an eruption of human wrath. It makes but little difference whether Dr. Cook reached the spot first or not. A dash, made with the advantages so largely provided by Commander Peary cannot detract from the merit of the man who pushed his way relentlessly against obstacles, following a plan that could not fail if persisted in. Dr. Cook is well known as an intrepid explorer. He received his first training under Peary in 1891-92. Subsequently he served a Belgian arctic expedition as surgeon; and later he fought his way to the top of Mt. McKinley in Alaska, which places him among the ranks of the most daring Alpinists. For these achievements he has been decorated with medals and other marks of distinction. He is no petty weakling, incapable of the deed he claims to have accomplished. But we cannot fail to note the characteristic of the man acting in the spirit of sport rather than in that of science. He gives no details; his observations seem to have been no more than sufficient to hold his course as a mariner might at sea; Peary, on the contrary, has given out data which present a picture to the mind even before he has flashed the great message that is promised. We see the drift of the ice, the opening and closing of 'leads' or channels, and patches of open sea; an itinerary is given; and we know that details of value to geography are coming.

The practical results, however, are few. Even if an observatory were planted upon the pole no more accurate astronomical observations would follow than are now possible from the multiplicity of stations all over the earth; moreover, the pole itself is not a fixed point; it migrates, as geophysicists long ago determined. Nevertheless, if the area of polar variation had been on land there is no telling but national pride would have resulted in ultimately establishing a tip-end observatory with the eagle

screaming from the dome. It is as easy to arouse a people to the doing of a fanciful thing as to expend money in providing the demonstrably economic. We venture to say that the interest of every man, woman, and child is keener over the discovery of the north pole, than it will be over the opening of the Panama Canal to traffic. The mind wearies of prose and account books; it needs some poetry, and extravagant chasing of Robin Goodfellow; it must also have some spectacle of spendthrift heroism now and again to

of the romance which has thrilled the world. Then came the determined search for the lost explorer, which yielded information of such value as to advance the knowledge of the Arctic regions so rapidly as to pave the way for the further successes of Kane, Hall, Nares, and that growing list of adventurers that has ended with Peary's conquest. It is interesting to note that the work of Nansen and Peary had already raised a presumption that the polar area was covered by water. The evident line of drift of

Map of the North Polar Region.

remind us that to be too terribly sane is to dull one's soul. The moral effect is the great gain from the splendid victory over the ice-guard around the pole. The map tells part of the tale of heroism displayed by the brave men who tried and failed. The story goes back, in fact, so far into the past that we read of the marvelous voyage of Pytheas in Grecian history. He certainly penetrated the land of the winter night. Modern quest for a recognized geographical spot began with Sir John Franklin. The story of the expedition of the *Erebus* and *Terror* has formed part

the *Jeanette* and of the Mellville-Bryant cask, had also rendered it nearly certain. The conditions to be met were well understood in advance, and success was the logical outcome. At last the quest of the pole is over; Mr. Walter Wellman, after taking good care for several years not to get actually started from Spitzbergen in his airship, is relieved from further embarrassment; and the world will now have to set up some other popular mystery to worship until the man with pluck and daring comes to scale the wall that hems it in.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

W. E. GORDON FIREBRACE is in Peru.

JOHN B. FARISH was in San Francisco.

J. D. IRVING is at Palo Alto, California.

CARNEY HARTLEY is in Routt county, Colorado.

JAMES W. NEILL passed through San Francisco.

WALTER W. DAVIS, of Leadville is at New York.

R. D. GEORGE has been at Kellogg, Iuaho, this summer.

A. H. LAWRY has left Goldfield, and is in San Francisco.

W. R. CHADBOURNE, of San Francisco, is visiting Leadville.

J. F. KEMP has been spending the summer in the Coeur d'Alene.

Audley H. Ackerman is in London on a brief holiday from Rhodesia.

H. B. TAYLOR has gone to Hinsdale, Colorado, on professional business.

C. W. CADDAGAN has returned to Los Angeles after a year's sojourn in Brazil.

P. H. ARGALL has been transferred from the Selby smelter to Pueblo, Colorado.

F. F. SHARPLESS has left New York for a trip through Colorado and Arizona.

J. W. FINCH has returned to Denver from Butte, Montana, and the Coeur d'Alene.

ROBERT SCHORR has gone to New York. He will be in San Francisco by October 1.

LEO VON ROSENBERG, of New York, was in Seattle and has gone to Butte, Montana.

S. F. EMMONS has been at Breckenridge, Colorado, and has gone to Ely, Nevada.

F. L. BOSQUI sailed from New York for London on the S. S. *Celtic* on August 28.

FRANK C. LORING has fully recovered from his illness and is now back at professional work.

HERBERT HAAS has postponed his journey to South America, and is now at New York.

W. H. SHOCKLEY has gone to Sobolinaya, Siberia, to examine the Kluchi mines for Hooper & Speak, of London.

CLIFTON H. KROLL, of Atkins, Kroll & Co., left on August 30 for Europe. He will visit England, France, and Germany.

CHARLES J. MOORE has returned to Colorado from Goldfield and will hereafter divide his time between Denver and Leadville.

FRANK L. SIZER has been appointed superintendent for the Balaklala Consolidated Copper Co., succeeding R. N. Bishop, resigned.

GEORGE R. FIELD, contracting engineer for the Risdon Iron Works, has resigned. He becomes assistant general manager for the Great Western Power Company.

R. N. BISHOP has resigned from the managership of the Balaklala mine, Coram, California. He will open an office at 1121 First National Bank Bdg., San Francisco.

An apparently unimportant suit brought in the district court at Butte by lessees of the Ticon mining claim, owned by James A. Murray, against the Anaconda Copper Mining Co. for something less than \$1000, and to determine the ownership of an orebody on the 500-ft. level of the Ticon mine, appears to be the entering wedge of the long threatened litigation between Mr. Murray and the North Butte and Anaconda companies over what is supposed to be the western portion of the rich Edith May vein. Murray's contention is that the vein does not have its apex in the Edith May mining claim, but that it belongs partly to the Ticon, which is situated between the Edith May and the Speculator claim, on which latter is situated the North Butte working shaft. About 60% of the original location of the Specu-

lator, the western portion, is owned by the Anaconda company, and the latter's portion adjoins and lies south of the Ticon. In the mining operations by the Ticon lessees they followed their vein and orebody, beyond the sidelines and mined under the surface of the Anaconda Speculator. The Anaconda company threatened injunction proceedings and tied up the smelter returns on the ore shipped. Murray then sank a new shaft on the Ticon, following the vein on its dip and traced the ore connection, his engineers claim, from the surface to the point where the ore was mined on the 500-ft. level, and suit was brought against the Anaconda company to settle the title and right to the money for the ore taken out. Unless the controversy is settled out of court, and Murray should be successful in the suit just brought, enormous litigation is likely to follow. The ore mined from the disputed territory by the Anaconda and North Butte amounts to many millions of dollars.

Dividends.

On Saturday, September 4, the Bunker Hill & Sullivan Mining & Concentrating Co. paid dividend No. 144 of \$45,000. This makes the amount of dividends paid since January 1, 1909, \$480,000, and the total to date \$11,151,000.

General Mining News.

ALASKA.

(Special Correspondence).—The Kuskokwim river has been considerably explored and prospected this season; it is estimated there are 75 miners on the stream and its tributaries. The Tuluksak, which flows into the main stream 300 miles above the mouth of the latter, has been the scene of limited placer mining. On the upper course of this Tuluksak and on Bear creek, that flows into it, seven men have made some valuable discoveries. Banlard & Kizer will clean up several thousand dollars. Fisher and Grant a like amount. They find bedrock at a depth of 2 to 8 ft. Some placer claims have been staked there. C. D. Scott, of Nome, spent a month this summer on the Tuluksak, and reports no available supplies in that region. Bethel, a Moravian mission and trading post, is 150 miles up-stream from the mouth of the Kuskokwim. A common route to the Kuskokwim is from the Russian mission on the Yukon, 80 miles easterly along a chain of lakes, with short portages between lakes. The mail route from Russian mission to Bethel is by way of these lakes and portages.—Reports from Porcupine, 38 miles from Haines, are that 270 oz. of gold were recovered as the result of a 20 hours run recently at the placer workings of the Porcupine Gold Mining Co., where E. E. Harvey is in charge.

Nome, August 10.

ARIZONA.

COCHISE COUNTY.

A body of copper ore assaying from 7 to 10% copper was opened by the cross-cut from the 1500-ft. level of the Junction shaft of the Superior & Pittsburg company. This discovery was made while working toward the Briggs shaft and is so encouraging that the company is planning to reopen that shaft about the first of the year. The company is doing considerable development work at the Cole shaft driving north and south on the tenth and eleventh levels and cross-cutting in both directions.—At the Irish Mag shaft of the Calumet & Arizona an orebody has been cross-cut on the 650-ft. level that runs from 15 to 17% copper.—At the Czar shaft of the Copper Queen the water conditions are much improved. The steam pumps that were running to keep the water from the summer rains down have been stopped and the electric pumps are handling the water easily. The copper output for August will be larger than that of July and will be approximately equal to May and June production. The Sacramento shaft is down 1600 ft., and a station is being cut at that point. A cross-cut will be run from here to the Lowell shaft.—On the 500-ft. level of the Shattuck the drift opened a body of cuprite that assays from 30 to 35% copper.—W. V. Richards, of Bisbee, has bonded the Leadville group in the Paradise district from George A. Walker. Operations are to be started by the first of December and hoisting machinery and pumps to unwater the mine installed. The property is one of the oldest in the district and has had a varied history. Located in 1879 a small amount of ore was shipped to the old Galeyville smelter, one mile below Paradise, but the mine did not become a paying proposition and was abandoned. The claims were re-located in 1889 and in 1890 and 1891, 29 cars of ore were shipped to the El Paso smelter from the 100 and 140-ft. level.—The cross-cut from the 120-ft. level of the Doran & Gallagher property intersected a vein of lead-silver ore with a small amount of copper. Larrieu & Cross are operating the mine under a bond.—H. D. C. Buford shipped a small lot of ore to the El Paso smelter that ran 20% lead.—The owners of the Savage property have stopped work and closed down the mine.

GILA COUNTY.

The Arizona Commercial Copper Co. has a large force of men at work on the sixth level blocking out the ore preparatory to the blowing in of its smelter. A drift has been run 650 ft. on the ore at this level. In the new smelter the blast-furnace is to be constructed to handle 500 tons per day at present but will be increased to 1000 tons at some

later date.—A 3-drill compressor is being installed by the Superior & Globe company and sinking will be continued with machine drills. The shaft is now down 475 ft. The company will cut a station at the 500-ft. point and cross-cut to the vein. The shaft will be continued to the 700-ft. level and lateral work started there before any stopes are opened.—The cross-cut on the 900-ft. level of the Arizona-Colorado has been driven 175 ft. toward the vein. S. C. Phillips is superintendent.

MARICOPA COUNTY.

L. F. Reynolds, of Morristown, has bonded the old Garcia claims in the Wickenburg district, and organized the Santa Fé Gold Mining Co. to operate them. A 300-ft. shaft has been sunk on a 2-in. vein that assays \$45 per ton. The two upper levels have been worked out and it is estimated that \$700,000 was taken out.

MOHAVE COUNTY.

A force of men has been started to work at the Gold Bar group near Cerbat. The property is situated on the gold belt that crosses that country and formerly produced considerable rich ore.—It is understood that the final payment is to be made on the Gold Cross property and work resumed at the mine.—At the St. Louis mine Dooley & Collins are driving a cross-cut on their lease to open an 18-in. vein of lead ore. A small amount of gold and silver is associated with the lead.—A heavy flow of water has been struck in the shaft of the Golconda mine at a depth of 360 ft. It is the intention of the company to cut a station at the 385-ft. level and commence stoping at that point.—The adit at the property of the Expansion Gold Mines Co., at Union Pass, opened a vein of free-milling ore. The company is erecting an experimental mill on the property. Charles J. Hutchison is superintendent.—A Chicago firm has secured a bond on the Portland group in the Music Mountain district and is cleaning out the old shaft preparatory to sinking.—A car of copper ore was shipped by T. S. O'Brien from the Bunker Hill at Cerbat.—The shaft of the Gold Bug mine is down 450 ft. At the 400-ft. level the ore was opened while cutting the station and found to be dipping from the shaft at a slight angle. When the 500-ft. level is reached a cross-cut will be run to the vein and drifts driven in both directions. O. B. Amsden is manager.—The Mammoth Silver Mining Co. made the initial payment of \$10,000 for the purchase of the Hackberry mine. The company has sunk a shaft on the property and opened a good vein of milling ore. The company also has an option on the claims of W. K. Ridenour and W. L. Kayser in the Wright Creek district.—E. L. Godbe, of Salt Lake, has purchased the interest of W. D. McCright in the McCracken mines and has secured an option on the balance of the old McCracken and Signal mines. A shaft on the property has opened a vein of lead-silver-gold ore to a depth of 400 ft.—A contract has been let to sink the shaft at the Horseshoe mine 300 ft. This will give a total depth of 500 feet.

YAVAPAI COUNTY.

A shoot of ore assaying 280 oz. silver has been opened on the property of the Zero Mines Co., 10 miles south of Prescott, an adit will be started to cut the vein at a deeper level.

YUMA COUNTY.

The management of the Clara Consolidated Gold & Copper Co. has decided to increase the capacity of its smelting plant from 450 to 700 tons per day on account of the large increase in ore reserves opened by recent development work. This addition will be completed by the time the Arizona & Swansea railroad is finished.

CALIFORNIA.

ELDORADO COUNTY.

The Alaufeseyte Products Co. has purchased the Vandalia mine and a number of other properties in that neighborhood and are preparing to open them in the near future.—Work is to be resumed at the Eagle King mine at Grizzly Flats this fall.

NEVADA COUNTY.

(Special Correspondence).—The electric pump recently

installed at the 2200-ft. level in the Empire is working satisfactorily. Another of the same type is about to be placed on the 3400-ft. level. On the 1100 a Lakenan pump is in operation. Sinking will be commenced within a few weeks. Forty stamps are dropping, and it is understood about \$60,000 is being turned out per month.—In the Deadman's Flat district considerable prospecting is going forward. Recent developments in the mines there have not been particularly satisfactory.—At the Sultana good ore is coming from the 600-ft. level and the mill is running steadily. Ore is being opened in the lower workings.—The Posey Canyon company has levied an assessment in order to carry on developments.—It is reported that H. G. A. Brunner, manager of the Conlan M. Co., will be here in a few days, and that arrangements will be perfected for the resumption of activities.—The pumps at the Pittsburg have lowered the water to the 80-ft. level, and machine drills are running on the 600 and 700. The new electric plant has been practically completed.—The Murchie mine is being examined by Los Angeles engineers, and it is probable that steps toward the opening of the property will be undertaken shortly.—A rich shoot of ore, believed to be the McMurray vein, has been cut beneath the McMurray shaft in the Delhi. Considerable bonanza ore is being extracted.—Twenty stamps are dropping steadily at the Champion. Most of the ore is coming from leases.—At the Mountaineer the new shaft is making good progress. Considerable ore is being taken from the old workings.—It is reported that the development will be more active in the Cold Springs.—More men are working at present in the Grass Valley-Nevada City district than for many years, and the 8-hour system has been productive of good results.

Grass Valley, September 6.

George A. Shelby has sold the controlling interest in the Golden State mine on Bear river to J. T. Hennessy, Thomas Gill, and associates of Grass Valley. The property contains 80 acres of good timber land, an excellent water right, and is equipped with a 5-stamp mill. An upper adit opened a rich shoot of ore which was run through the mill with good results and a lower adit has been started that will give 400 ft. of backs.—Albert R. Herman, the president of the Rudolph-Herman Co., is authority for the statement that the company will commence development work at its property near Spenceville at once. A number of specimens of copper ore have been taken from the claims.—The raise from the adit level to the surface of the Fairview mine has been completed. It was driven a distance of nearly 500 ft., and was in pay-ore the entire way. Drifts are being run in both directions on the ore and a large tonnage will be blocked out by the time the mill is completed. The plant is situated 800 ft. below the present level and a lower adit will be driven at some future date to open the vein at this point.—The Erie mine, near Graniteville, has been purchased by a group of Wheeling capitalists from George Mainhart, and operations will be resumed at the mine some time this month. R. G. Eckis will manage the affairs of the company.—The 5-stamp mill at the El Oro mine in the Graniteville district was destroyed by fire. The mill was a comparatively new one having been built about a year ago.—Bray Wilkins has resigned from the position of manager for the Idaho-Maryland Development Co., and Robert Nye, of Grass Valley, has been appointed as his successor.—A vein of good ore has been opened by the adit at the Gold Canyon mine on the middle fork of the Yuba river.—A 12,000-lb. boiler is being hauled to the Birtchville mine near Graniteville.—The United States Mining & Smelting Co. has purchased the Iron Mountain mine at Indian Springs from M. C. Taylor. Considerable iron ore was shipped from the mine when it was first opened by Mr. Taylor, but the ore changed to a copper sulphide with depth and the work was stopped. About five years ago Henry C. Schroeder secured a bond on the property and blocked out a large amount of ore. Since that time he has been trying to interest some large company and has at last succeeded in making the sale to the United States company.—Ground has been broken for the new 3-compartment shaft at the Brunswick mine. It is estimated that the shaft will intersect the vein at a depth of

1250 ft., and no cross-cutting will be done till that point is reached.

PLACER COUNTY.

The Denver syndicate, operating the Dewey mine under bond, is to prospect the vein on the Dodd's ranch. A small shaft has been sunk on the property and some good ore taken out.—F. A. Moss has run a 100-ft. adit, sunk a shaft, and cross-cut the James vein.

SHASTA COUNTY.

The dredge of the United States Gold Dredging Co., on Middle creek, broke in half owing to a large amount of machinery placed in the boat. The cost of the dredge was \$75,000 and it had just been overhauled and fitted with new machinery at an expense of \$15,000. The stern struck on a rock and is still above water but the bow is 15 ft. below the surface.—The storage bins at the terminal of the aerial tram at the Mammoth smelter, will have a capacity of 20,000 tons, and will be completed some time this month. A large portion of the structural steel for the addition to the smelter has arrived and an extra force of men put to work on the building.—A 75-hp. electric hoist has been ordered by the Mountain Copper Co. for the Iron Mountain mine.—A heavy flow of water was struck by the diamond-drill in the Summit mine.—The committee appointed to interview the managers of the smelters reported to the Association that they had seen R. T. White of the Balaklava Copper Co. and A. S. Haskell of the Mammoth Copper Co., and that neither of those gentlemen had the authority to promise anything in behalf of the companies, but would consult with the other officials to see what could be done and asked that any action be postponed till the first of October. The Association will undoubtedly delay any further work till the smelter managers give them an answer. The committee visited the Bully Hill smelter, at Winthrop, though no claim is made that it is doing the farmers any damage.

SIERRA COUNTY.

The ore-shoot at the Oakland mine has widened till it is now 18 inches.—W. R. Warton, of Los Angeles, is to take over the Cleveland mine near Sierra City. A small force is to be kept at work this winter and more extensive development done in the spring.—The company holding a bond on the Nugget Nell property has started drilling to determine its value.—George W. Scott and associates, of Sacramento, have purchased the Fischer hydraulic mine near Sierra City and are making arrangements to work the property this winter. There is an excellent site for a restraining dam below the mine and the California Debris Commission will be asked for a permit to build a restraining wall to impound the tailing. A ditch is being dug that will bring the water to the mine under a high pressure.—Francis B. Voyle has dropped his suit against the Sierra Mining Co., operating the Alaska mine near Pike City, giving as his reason for this action that the company is heavily bonded and would not be able to settle if his suit was successful.—Considerable activity is manifested in the old mining camp at Brandy City. About 100 men are working in the neighboring mines and application has been made to have the postoffice re-established.—The Hewitt Brothers have sold their property on Hopkins creek to C. B. Wingate who is representing a syndicate of Scotch capitalists.—The Nissen mill at the Red Star mine has been completed and is running on good ore.—W. F. Corbett is to sink a winze on the vein that crosses the San Fernando claim.

TRINITY COUNTY.

M. A. Brady is opening a 2-ft. vein on the head of Little Weaver creek 6 in. of which runs from \$30 to \$40 per ton.

TUOLUMNE COUNTY.

The north cross-cut on the 400-ft. level of the Soulsby mine, operated by the Bagdad-Chase Mining Co., opened a 2-ft. vein that assays over \$100 per ton. This gives 400 ft. of backs on a considerable length of the ore-shoot.

YUBA COUNTY.

The Marysville Quartz Tunnel & Mining Co. has bonded a considerable portion of the Yuba channel near Smartville and is preparing to drill the ground to ascertain its value

for dredging. Considerable rich gravel was washed in this vicinity in early days and some rich, though pockety quartz veins, opened.—It is reported that the Marc Anthony mine is to be bonded and a deep shaft sunk on the property.

COLORADO.

GILPIN COUNTY.

The Fifty Mines Co., at Black Hawk, shipped a \$5000 gold-bar to the Denver mint. The bar was from the Fifty mill which is running on ore that is mined from the Gregory, Bobtail, and Fiske veins from the 1100 to the 1400-ft. level. On the Gregory vein the company has driven 200 ft. at the 1400-ft. level giving 325 ft. of backs. It is expected that the company will sink the Cook shaft to the 1600-ft. level shortly.—Surface water from recent rains has raised the water in the Concrete mine on Gunnell hill above the ninth level so work has been abandoned in that portion of the mine till it is drained by the Newhouse tunnel which will be in about six months if the tunnel is driven at the present rate. The company is breaking a large amount of ore in the stopes, the surplus being sent to the mills at Black Hawk, the rest remaining till the company builds a reduction plant. E. S. Moulton is superintendent.

GUNNISON COUNTY.

The adit of the N. C. B. Mining Co., at Sherrod, is in over 600 ft., and another adit has been started to open a vein northeast of the one the company is now working toward. T. C. Clayton is manager.—The quarries at Marble have been re-opened and a new crew of men put to work. There has been threats of trouble by the strikers so the company has several deputies at the property.—A new orebody has been reported from the Fanny Fern mine near Lake City.

EAGLE COUNTY.

At the Champion mine, in the Red Cliff district, an incline has been sunk 2400 ft. A large amount of development work has been done on the property and regular shipments of sulphide ore are made to the smelters. James A. McKeen is manager.—The Eagle Mining & Milling Co. has opened large bodies of low-grade ore in the Iron Mask mine and has nearly completed a mill for their treatment.—On the Foster claim a shoot of ore has been opened on the surface that assays between 500 and 600 oz. silver per ton.—The Rio Grande Mining & Leasing Co. is opening a body of ore that assays \$60 per ton.

LAKE COUNTY.

A raise has been driven 50 ft. from the 700-ft. point in the Houston adit on a 2-ft. vein of ore that assays 35% lead, 104 oz. silver, and \$14 gold per ton. A. S. Sharp is manager.

OURAY COUNTY.

The average of a number of assays of samples taken from the surface of the Sutton group under bond to the Slick Brothers Mining Co. was \$44 per ton. At one point a trench cut an 18-in. vein that assayed 4000 oz. silver and \$40 gold per ton. This was associated with a gray copper ore and was not included in the average of the samples.—The compressor of the Calliope Mining Co. has been moved into one of the buildings at the Bachelor mine and power obtained from that company. As soon as the adit now under way unwaters the old workings the company will be in a position to commence shipping.—The Amity Gold Mining Co. has completed winter quarters for its men and is working on the adit to open its orebodies at depth. It is estimated that it will require 1500 ft. of work to cut the vein.—One car of ore is being shipped per day from the Morning Star mine which has been leased to Ramstead & Sneva.—The Silver Ledge mine has been unwatered to the 400-ft. level and samples are being taken from the vein. As soon as the water is out to the 500-ft. level a large Cornish pump will be installed and the whole mine thoroughly sampled. Marvin Jessey is superintendent.—Grading for the new compressor and hoist at the Congress has been started and a contract will be let to sink the shaft as soon as this work is completed.

PARK COUNTY.

The company which recently secured ground for a smel-

ter at Alma has commenced grading for the foundations and has given out the statement that the plant will be finished within a year. The company has had ore-buyers in the field for some time and an ample supply of ore is assured.

SAN JUAN COUNTY.

The Continental Mining Co. has driven 700 ft. along the vein on the Buffalo Boy claim. The vein is from 4 to 9 ft. wide, and average samples from the dump ran \$23 per ton, with picked samples assaying over \$4000 per ton. The company is shipping regularly from the Old Abe and Tenderfoot claims and is planning to erect a concentrating mill on the property.

SAN MIGUEL COUNTY.

The Sackett Brothers, of Telluride, who have been operating the Contention mine under a lease for the past year, have opened a body of ore that assays \$3300 per ton. They have also secured the old mill on Bear creek and built a tramway to it from the mine. The mill is now in good order to handle the low-grade ore and the high-grade will be shipped to the smelter.

SUMMIT COUNTY.

A new motor has been purchased to haul the ore from the Wellington mine to the mill. The mill is turning out about 9 tons of concentrate per day.—A long adit is being driven by lessees on the Dunkin property to open the ore at depth. A great deal of rich ore was taken from the upper levels of this property in its early history.—The Rothschild mine, near Argentine, is to resume operations some time this month.

TELLER COUNTY.

Sidney Bartlett and W. F. Burns, operating a lease on block 4 of the Ida May mine on Raven hill, opened a rich ore-shoot at a depth of 42 ft. The vein is from 18 in. to 2 ft. wide, 14 in. of which runs from \$100 to \$200 per ton. The lessees are preparing a trial shipment for one of the local mills.—R. P. Russel has secured a lease on the Twin Sisters mine and is re-timbering the shaft preparatory to opening the property.—Burns & White, leasing block 85 of the Gold Hill group from the Stratton estate, shipped 800 lb. of ore that assayed \$400 per ton. The ore was taken from a narrow seam and a larger shipment is being prepared.—Van Tilborg, Young & Reid are to resume shipping from their lease in the Wilson mine. The cross-cut from the 300-ft. opened 2 ft. of milling ore.—The August production of the Cresson mine was over 3000 tons which is the largest output in the history of the mine. The main shaft of the company is now 1000 ft. deep, and it is expected that the company will commence sinking shortly.—A. E. Carlton has secured a 3-years' lease on the properties of the Joe Dandy Mining Co. The shaft is being re-timbered and the buildings and ore-bins, which were destroyed by fire last fall, re-placed.—The Happy Year Leasing Co. has installed air-drills in its lease at the John A. Logan shaft, and has made arrangements to obtain air from the power plant of the Western Investment Co. Plans are being drawn for the erection of a cyanide on the property. H. W. McRae, of Cripple Creek, is secretary for the company.—A new orebody has been opened on the 540-ft. level of the Aileen mine and nine cars of ore per week are being shipped from the property.—The Doctor Jackpot Mining Co. paid a dividend of \$15,000.—Two cars of \$50 ore was shipped from the Milhoan & Mart lease on the Nightingale mine.

IDAHO.

IDAHO COUNTY.

The 10-stamp mill at the Big Jumbo mine in the Buffalo Hump district has been purchased by M. J. Sweeney and Andrew Prader and is being moved to the Crackerjack property. The Crackerjack is now working on a 50-ft. orebody. There is a 10-stamp mill on the ground and the company is installing a water-power plant to operate the mill and compressor.—Duhrkop & Gribi are opening some good ore on their claims on Moose creek.

OWYHEE COUNTY.

A 500-ft. shaft is being sunk from the Dewey adit of the Trade Dollar mine.—The adit on the mill-level at the Ban-

ner mine cut the vein when in 1500 ft. at a vertical distance of 700 ft. below the outcrop. The vein is 4 ft. wide. Robert Walker is in charge of the work.—A 100-ft. adit on the Berg mine in the Rooster Comb district opened a shoot of oxidized ore. In addition to the oxidized ore, which is free-milling, there is a seam of smelting ore on the foot-wall. H. L. Benson is in charge of the work.

SHOSHONE COUNTY.

Snowstorm mine in the Coeur d'Alene is steadily increasing its output, and at present is shipping 15,000 tons per month. The bad ground cut in the No. 4 adit has been circumvented by driving around it to the west and good headway is being made. The miners got around the break last week, and a little ore has already been cut. They are within 60 ft. of the main orebody in No. 3 adit.—Plans are being made for the enlargement of the Monarch mill, situated east of Murray. The plant now has a capacity of 50 tons per day, and this will be doubled or trebled. The mine shipped several carloads of clean galena and concentrate three years ago, but owing to the expensive wagon-haul to Wallace, shipments were suspended until the completion of the railroad to the mines east of Murray. The Monarch is the most extensively developed lead-silver mine on the north side of the Coeur d'Alene, having 6000 ft. of adits and shaft, and ore reserves approximating 30,000 tons, which has been increased by recent exploration. The concentrate runs about 50%, while the clean galena shipments exceed 60% lead, the average silver content going about 12 oz. per ton.—H. F. Samuels, manager and principal owner of the Success mine in the Coeur d'Alene, announced that shipping will begin in a week. The mill is in working order and mining operations are under way. The work of blocking out the ore has been going on for several weeks, and now stoping has been started. It is expected to ship more than 1500 tons per month.

MISSOURI.

NEWTON COUNTY.

(Special Correspondence).—For the first time in a period of months all the mills in the Spring City camp are active. Five plants have recently started, the Alpha, Alladin, McKee, Microbe, and Sunrise. They will aggregate an output close to 1500 tons per day upon ore running from 5 to 15%. The last plant to start production is the Alladin, built to replace a mill destroyed by fire. Previous to its destruction the company had just opened a rich body of galena ore.—The Hancock is one of the latest developments and is said to be one of the richest. The shaft is down 144 ft., exposing a 12-ft. face of high-grade ore, estimated to run 20%. The entire run has not yet been penetrated, and when it is drifts will be started.—Another large mill is being built in this camp just below the site of the old Delta and will be used to re-work the old tailing pile left from the operations of this plant. There is considerable ore in this waste, as the former mill was not equipped with sludge tables or sand jigs. When the tailing pile is re-worked the mill will be used as a custom plant, as such a mill is badly needed in this camp.

Spring City, September 4.

MONTANA.

MISSOULA COUNTY.

Two miles is the length of a tunnel planned to cut the orebody at a depth of 2000 ft. in the Monitor mine and tapping numerous properties in the vicinity near Saltese. The Chicago, Milwaukee & Puget Sound Railway Co., is reported to be backing the undertaking, the purpose being to control the enormous tonnage. Among the properties which would be tapped by the big bore is the Copper Age, owned by Charles Heidenrich and his associates. The recent important find in a drift on the 700-ft. level of the Monitor, which has been confirmed by H. F. Samuels, manager of the property, has demonstrated that there is commercial ore in that part of the Coeur d'Alene and indicates that another mine will be added to the copper shippers in a short time. The latest find is not the shoot opened some time ago in the upper levels. It is 4 ft. wide, but its length

has not yet been determined. The company has a large crew at work, and as there is already more than a car of high-grade ore on the dump it is likely shipping will begin soon.—The Hemlock Mining Co., operating near Saltese, is making preparations to sink on its orebody. A 150-ft. drift opens galena, copper, and silver ore all the way in. One 60 and one 70-hp. boiler will be put in and a 20 or 30-hp. hoist installed. When this is completed, the shaft will be sunk to the 200-ft. level, after which the vein will be cross-cut and driven upon.

NEVADA.

CLARK COUNTY.

The cross-cut from the 100-ft. level of the Duplex-Contact cut a foot of quartz that is stained with copper and assays well in gold. The plant recently installed by the company is running satisfactorily.—The Yellow Pine Mining Co. is to build a concentration plant at its mine in Goodsprings. J. F. Kent, manager for the company, has been in the lead and zinc districts of the Southeast to study methods of concentration and the plant will be designed similar to those visited by Mr. Kent.

ESMERALDA COUNTY.

The August output of the Goldfield Consolidated Mines Co. was 22,160 tons, which netted the company \$447,000. This includes 150 tons of \$600 ore that was shipped from the Hampton stope. A spur is being constructed from the Consolidated railroad to the Clermont dump and ore-bins with a capacity of 500 tons will be constructed at the shaft so the ore will be emptied into them from self-dumping skips.—The Burke lease on the Belmont mine at Diamondfield has opened a 10-ft. shoot that assays from \$60 to \$75 per ton.—The mill of the National Ore Purchasing Co. at Rawhide has been completed and is running on custom ores. The first ore crushed by the mill was a low-grade lot taken from the Truett claims. The ore is reduced to 1 in. by a gyratory crusher, passes through rolls set to ½ in., is sampled, and is reduced to 30 mesh by two Graupner mills. The pulp passes over Hoyt riffles, through Callow separators, and to Pachuca tanks. From the tanks it goes to a Hunt filter, the solution going to a Merrill press, and the tailing stacked.

LANDER COUNTY.

(Special Correspondence).—The Austin Manhattan Mining Co. has decided to re-open the Union mine. A drift will be run from the lower workings to the Ophir and the latter made the main working shaft. The station at the juncture of the main adit and the Frost shaft has been completed. It is provided with a 60-hp. gasoline hoist.—Lessees on the Golden Eagle have opened a good shoot of ore running \$90 gold and 250 oz. silver.—Several finds of minor importance have been reported from nearby properties during the past two weeks.—Lessees on Nevada-Omaha ground at Battle Mountain have cut a shoot of high-grade ore. The vein is from 3 to 6 in. wide and is said to run \$42,000 at Battle Mountain have cut a shoot of high-grade. The Austin, September 6.

LINCOLN COUNTY.

(Special Correspondence).—The Homestead company is arranging to sink the Fraction shaft to the 1000-ft. level. A new hoist and several machine-drills will be installed. W. H. Perkins is manager.—The Philadelphia-Searchlight has commenced operations with a diamond-drill and will thoroughly prospect its holdings to a depth of 1000 ft.—The Searchlight Parallel will resume operations some time this month.—The Memphis Mining & Milling Co. is arranging for the installation of a hoist and compressor. A. L. Hill is manager.—The Pompeii will start the sinking of its main shaft within a few days.—At the Quartette good ore is coming from the lower levels. The mill is operating steadily.—The Combination reports the uncovering of a 12-in. vein running \$50 to \$200 per ton on the Lloyd claim.—A hoist is being installed at the Eureka Searchlight.—The Santa Barbara Mining & Milling Co. is preparing to install a concentration plant.—The vertical shaft of the Eldorado-Occidental is down 200 ft. with a large body of \$10 ore opened. Cross-cutting in search of

water for the new milling plant is going on. Grading for the mill is progressing rapidly. The plant will have a daily capacity of 50 tons. A. G. Austin is manager.—The Silver Legion company expects to resume work soon. The shaft will be sunk 500 ft. The vein assays from \$10 to \$200 per ton in gold and silver, the latter predominating. John Sartain is superintendent.—The Oxnard has raised funds to sink the shaft to the 600-ft. level. Near the 160-ft. level an 8-ft. body of high-grade silver ore was opened when the mine was last worked.—The entire district is active and a number of properties are being developed.

Searchlight, September 6.

LYON COUNTY.

The citizens of Mason valley have subscribed for \$37,000 worth of bonds of the Nevada Copperbelt railroad and contracts let for the grading and furnishing of supplies.—The Nevada Calumet company near Yerington has instructed its superintendent to draw plans for the construction of a reduction plant.

NYE COUNTY.

(Special Correspondence).—Two veins are being opened on the 500-ft. level of Montgomery Shoshone. The third and fourth levels are producing most of the ore for the mill. The plant is handling about 215 tons per day.—It is reported here that the Goldfield Consolidated Co. is back of the recent improvements to the Mayflower mill and the more vigorous development instituted at the mine.—It is rumored that attempts will be shortly made to resume activities at the Homestake King. Two of the directors are here looking over the property.—Several lessees are working on Tramps with good results. The Vucovitch lease is extracting \$100 ore from a narrow vein and is opening considerable shipping ore.—The Bonnie Clare is showing splendidly. Large bodies of \$18 ore have been opened and the company is arranging for the addition of considerable machinery to its mill. An effort is being made to have the railway companies build a branch line from the station of Bonnie Clare to the mine, a distance of 10 miles. The company offers to guarantee 100 tons of ore per day from its own properties. Andrew J. Trumbo is manager.—The Gillespie lease on Jim Butler reports a 6-in. stringer assaying \$400 per ton. The shaft is down 150 ft.—A. D. Meyers and T. A. Johnson are endeavoring to secure control of the Johnnie Mining & Milling Co. It is asserted that the present board of directors is not handling the property to advantage.—Manhattan quartz mines are evincing considerable activity. At the Stray Dog a station is being cut on the 240-ft. level and an electric pump will be installed. Sinking will immediately follow. Excavation for the new mill is progressing steadily. It is possible that a sampler will be added.—At the Indian Camp a west drift and north cross-cut are being extended from the 120-ft. point.—George H. Bradford has been sampling the ground of the Manhattan Independence Consolidated Co., and if the results justify, it is planned to move the Talmore mill from Rawhide to Manhattan.

Rhyolite, September 4.

WHITE PINE COUNTY.

The August output of the Nevada Consolidated Copper Co. approximated 6,000,000 lb. blister copper.—The raise for the shaft at the Giroux is above the 760-ft. level. The ore is trammed through that level to the Alpha shaft and raised by the Old Glory hoisting equipment which has been recently moved to that point. The Giroux drills on the Butte Ely ground have been in poor material during the past week.—On the Coppermines, Hidden Treasure, Ely Calumet, and other properties of that neighborhood a number of leases have been let and active work commenced on the lead-silver veins of the camp.

NEW MEXICO.

GRANT COUNTY.

The Chino Copper Co. filed incorporation papers with Nathan Jaffa, Territorial Secretary. John M. Sully is the New Mexican representative with headquarters at Santa Rita. The capitalization is for \$3,500,000 in 700,000 shares, \$2,125,000 worth of which has been sold.

OREGON.

BAKER COUNTY.

W. H. Schofield has been investigating the ore supply in the neighborhood of Sumpter and the Seven Devils country to ascertain the possibility of obtaining a supply of ore large enough to warrant starting the smelter.—The Keystone Mining & Reduction Co. has leased the California mine in Cable Cove and is re-opening it. Richard Addoms is manager.

UTAH.

BEAVER COUNTY.

A new company has been formed to take over the Nip and Tuck property. There are eight claims in the group and some good lead-silver ore has been opened. George Weston is manager.—The drift on the 150-ft. level of the Progressive mine is following a streak of rich ore. The Progressive joins producing properties, and it is hoped that the streaks will widen enough to put the mine on a shipping basis.—There are over 100 tons of ore on the dump of the Golden Reef mine awaiting shipment to the smelter. The ore averages \$30 per ton.

SUMMIT COUNTY.

The Little Bell in Park City is now shipping ore from the 700-ft. level that assays 30% lead, 96 oz. silver, and small amounts of copper and gold. A winze has been sunk 259 ft. in ore from that level.—The shaft at the New York mine has been unwatered and sinking resumed.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—Negotiations are in hand for the re-opening of the Tom Thumb mine, now owned by the Midget Gold Mining Co.—During August the New Republic Mining Co. shipped 260 tons of ore. The winze below the No. 4 level of the Republic mine is being unwatered, preparatory to re-opening the fifth. The drift on the vein, southward from the old workings, on the No. 1 level is running on \$100 ore. A cross-cut shows the width of the ore to be 2½ ft.—The lessee of the San Poil mine has driven 200 ft. southward on the vein, on the No. 1 level, and run into a body of ore that assays \$18 per ton.—The Belcher Mining Co. has equipped the tramway from the No. 2 adit level to the ore-bunkers at the upper terminal of the Belcher Mountain railway and placed it in commission. The Belcher mine will soon be in more active operation than ever before in its history. The ore now blocked out in the mine is estimated at about 250,000 tons. A 6-drill compressor is being installed, which will be driven by a 40-hp. engine. The company has leased the Belcher Mountain railway and contracted for the delivery of the first 1000 tons of ore to the Granby smelter, at Grand Forks, B. C.—Work has been resumed at the Oversight mine, and it is reported that operations will soon be resumed at the Copper Key mine.—Jasper King, manager of the Walla Walla mine near Keller, is authority for the statement that the company will install a compressor and drills at the adit it is driving and will increase the force of men at the mine.

Republic, September 3.

JEFFERSON COUNTY.

(Special Correspondence).—The Tubal Cain Copper & Manganese Mining Co. is opening a mine on Iron mountain, in the Olympic mountains, 40 miles from Port Townsend, where four or five veins are to be opened by a cross-cut that will intersect them at a depth of 2000 ft. The cross-cut is now in over 900 ft., and by driving 200 ft. farther the first vein will be opened. These have all been prospected and sampled at the surface, showing the presence of copper glance, chalcopryite, and native copper. Through much of the ore there is some silver and gold. The drill-work is being done by air-drills, the compressor for same being driven by water-power direct, the pipe-line bringing water from the Dungeness river to a Pelton wheel. The mine is reached by a railroad trip of 24 miles from Port Townsend, thence 18 miles by trail. Victor A. Tull, of Seattle, is general manager for the company, and S. Marpel is superintendent.

Port Townsend, September 6.

Special Correspondence.

JOHANNESBURG, TRANSVAAL.

Labor Economy Underground—Rock-Breaking and Shovelings.—Exhaust-Steam Turbines.—First Output of Crown Mines.—Mica and Graphite.—Rapid Development.

The shortage of native labor, felt with particular force by the several companies which have lately erected new mills or extended old ones, is now turning the attention of managers to ways and means for reducing underground labor. The most generally adopted expedient is the use of machines, but hand-stopping in nearly all cases is cheaper per fathom, apart from the advantage that it admits of closer sorting of waste, and often tends to narrower stopes. The use of machines will often result in bringing down several more inches of waste from the hanging wall than when doing hand-work. Small stope-drills give promise of alleviating difficulties, but still hand-labor remains here the cheapest system. With a labor-shortage, there is, of course, no choice and more stopes are constantly being started with machines. Another sort of underground work which provides scope for economy in labor is shoveling in stopes (or 'lashing' to use the local term). The older outcrop mines are much steeper than the newer deep levels, and it may be roughly estimated that half the stopes of the Rand now dip at 35° or less. In some areas a dip of 20 to 30° prevails, and it is in these especially that means can be found to reduce the number of 'boys' or Kaffirs on 'lashing'. The question is periodically brought into prominence. On each occasion there is a formidable array of schemes, and a thunder of arguments. Each time some enthusiast proves conclusively, on paper, how he can save a large amount (10½ to 11½d. per ton seems a popular estimate with those who have not the pluck to claim the full shilling), by some 'new system'. The fact is that each case requires individual consideration. No general rule can be laid down. Chutes are used in many mines with success. Shaking chutes are favored where the hanging wall is good. Aerial gear and gravity planes also have their advocates, and in some properties cross-cuts are run into the foot-wall to meet 'passes' coming from the intermediate stope-tracks. Little reliable information is available as to the relative merits of the different methods. The figures given out are often biased, and are more commonly compiled to support some previous contention than to lead to the cold truth.

Upon his return from the States, after an absence of three years, J. W. Kirkland has delivered a paper upon 'Exhaust-Steam Turbines' before the South African Association of Engineers. The exceptionally large and 'weighty' attendance of members and visitors indicated the recognition of the importance attached to the subject. Mr. Kirkland gave a full description of how profitably and easily the available energy of steam in the lower pressure-ranges of expansion can be transformed into useful work by means of the exhaust or low-pressure steam turbine. He made an estimate of the cost of electrical energy developed by the exhaust-steam from a typical mill-engine room on the Witwatersrand, and on reasonable assumptions arrived at the remarkably low figure of 0.22d. per kw.-hr. including fixed charges. His calculations and conclusions are held to be so startling, that a long discussion is likely to ensue. At the same time, it is safe to declare that more than debate will follow. The possibilities of the low-pressure steam turbine have been engaging the attention of local engineers for a long time, and its introduction will soon be widely seen at the mines and elsewhere. A. M. Robeson, chief mechanical engineer for Eckstein & Co., pointed out their peculiar applicability to provide for increases of compressor-capacity. Time and again the mining engineer calls on the mechanical department for 'more air' (possibly as the result of an unexpected exodus of native laborers and the demand for mechanical substitutes), and then the question

arises how to most cheaply and simply make the increase. It is thought that further stage of compression can be most economically effected on the rotary principle in conjunction with existing reciprocating compressors and prime-movers. Electric power from central stations is now the order of the day. Nevertheless, the exhaust-steam turbine has a great field for service as an auxiliary to steam-plants already erected.

The Crown Mines, Ltd., has declared its first output, and it is interesting to compare the results with those recorded by the East Rand Proprietary, the subsidiaries of which were amalgamated a year before. Tabulated, the July figures were as follows.

| | Crown Mines. | East Rand Proprietary. |
|-------------------|--------------|------------------------|
| Stamps | 675 | 820 |
| Tube-mills | 15 | 15 |
| Tons milled | 132,724 | 154,000 |
| Yield | £213,773 | £222,525 |
| Profit | £109,950 | £106,201 |

Working costs on the former group were 15s. 7.7d. per ton, against 15s. 1d. per ton milled on the latter.

An attempt is being made to boom mica in the northern Transvaal. The mineral occurs in a form and quantity sufficiently promising to attract attention from economic geologists, but there is at present no cause for rejoicing over the advent of a 'new industry'. The promoters of the syndicate attempting to work the deposit have apparently read much literature on the subject of mica and its commercial uses, which course of study might well have been postponed until the possibilities of production are determined. A good deal is also heard of graphite prospects in the northern Transvaal. A venture floated to work a graphite 'mine' in the Zoutpansberg district some months ago appears to be sound and well conducted, and your correspondent, with some experience in Ceylon plumbago, can speak for the high quality of samples coming from the property. The persistence of the vein requires further investigation.

New development records have been made by the New Modderfontein. Two contractors in the East mine made an advance of 826 ft. in 156 consecutive shifts. This was in an ordinary drift, presumably about 7 by 5 ft. The average rate works out at 5.3 ft. per shift; a round, in order to give this advance, must have been blasted every shift. The previous record for the Rand was in the Van Dyk mine, when 323 ft. were driven in 62 shifts, equivalent to 5.2 ft. per shift. The New Modderfontein's achievement is the more creditable in view of the larger period. In both cases two 3¼ Ingersoll Sergeants were used. The most important conclusion to be drawn from these special performances, as from more general experience, is that the East Rand provides better breaking ground than the Central, and that development-costs per foot may be estimated on a lower basis.

NOME, ALASKA.

Wild Goose M. & T. Co.—Union Mine.—Thawing Methods and Costs.—Wonder Dredging.—Dredge-Pool Thawing—Anvil and Ophir Creeks.—Beach-Mining Scheme—Candle District.

The Wild Goose Mining & Trading Co. is operating three hydraulic elevators on Ophir creek, in Council district. Their location on Ophir is 15 above. Operations began in 1900, and the work is profitable. This season work started June 7, and will probably close about October 1. The water-supply has been a little short during a part of this year, although late rains have helped. On Ophir creek this company employs a force of 85 men. The placer-ground, in creek beds and on benches, is 10 ft. deep to bedrock, and the work extends eight miles on Ophir. The company's ditch conveys the water from Parantulk river to the upper end of Ophir creek, thence through the canyon-ditch along the course of the creek, which empties into the Niukluk river, on which Council is situated. The Wild Goose company is also laying a 42-in. pipe-line to carry water from the

Grand Central stream over a divide into the Nome district, for its own use, and to sell to other operators.

Fleming Bros. & Hanks operate the Union mine through two shafts on Flat creek, on the tundra, three miles out of Nome. It is 52 ft. to bedrock. In one shaft a cage and car are operated; in the other a self-dumping bucket of 1 cu. yd. capacity. The shafts are 200 yd. apart, and about the same yardage of pay-dirt is hoisted from one as from the other, each shaft having its own steam plant for hoisting and thawing, using crude oil as fuel. Operations have continued here for some time, and between seven and eight acres of bedrock have been cleaned, the slopes being 4 to 5 ft. high, the pay-dirt taking in from $2\frac{1}{2}$ to 3 ft. of the schistose-slate bedrock, and from 8 to 14 in. of the overlying gravel and sediment. About 2000 ft. of thawing-face is maintained, or 128 steel-points per day; it takes 40 cars, holding 40 pans each, with two men to the car, to handle the ground as fast as it is thawed. The calculation is to take out 10 cars to the point per day. The points, $6\frac{1}{2}$ ft. long, are set horizontally, 18 to 24 in. apart, and one man, skilled in the work, can look after 72 points. In this mine there is no wheelbarrow work, as all the dirt to be hoisted is shoveled into mine-cars. For this work there are 7000 ft. of T-rail track. The seepage of water is considerable, and a centrifugal pump is stationed near each shaft to keep it out of the workings. A force of 70 men is employed, mostly underground, and on an average they hoist 1100 cars of pay-dirt per day. The estimated cost is 65c. per car for thawing, shoveling, hoisting, and sluicing. The principal thawing is done at night, and there is a clean-up of the sluice-boxes every third morning, each clean-up yielding from \$2500 to \$3000. Along with the placer-gold there is obtained a concentrate, consisting of iron sulphide, hematite, and arseno-pyrite, carrying gold and silver, making a product worth \$200 per ton. This mine is fortunate in having plenty of water, the supply being taken from a small lake on the tundra, on the margin of which is the pumping plant. In this is a 40-hp. M. & W. engine, and a 10-in. special Byron Jackson centrifugal pump, running 15 hr. per day. The water is pumped 2000 ft. horizontally, and 34 ft. vertically to the sluices, at a cost of \$21 per day. The distillate used for the engine 60 gal. per day, and costs $20\frac{1}{4}$ c. per gallon. The crude oil consumed at the hoisting and thawing plants amounts to 20 bbl. per day. The operating force, which works harmoniously, is as follows: E. E. Fleming, general manager; W. Stewart Fleming, superintendent; F. O. Hanks, sampler and handler of bullion; Harris D. Longfellow, Geo. W. Glass, John Spencer, and M. Dekks, foremen. This mine, being low-grade, is made profitable by the application of careful and close methods.

The Wonder Dredging Co., managed by E. E. Powell, is operating on Wonder creek, three miles from Nome, in an area of uniform ground. The dredge was built last winter by J. E. Powell and Mr. Lytle, and began work June 12. It is electrically operated, is steam-heated, has 9-cu. ft. buckets, and is calculated to handle 2000 to 2500 yd. per day. The depth from surface to bedrock, is about 60 ft., the buckets taking up about 4 ft. of the schist bedrock, which occurs in partly decomposed slabs. Everything operates satisfactorily, and they anticipate keeping at work till January 1, by enclosing the machinery fully, and keeping the pool heated artificially. Two more dredges are being built and are doubtless now in operation. One is that of the Nome Mining Co., on Bourbon creek, the present dredge being the result of a reconstruction of the one that had an unfavorable record a year or two ago; the other is that of the Gold Beach Dredging Co., on Dry creek, close to town. The Dry creek dredge, reconstructed from one formerly built at Portland, has 5-cu. ft. buckets, and is intended to dredge to a depth of 30 ft., in ground that will have to be thawed. H. Greenberg is financially backing the enterprise. The interest in dredging at Nome is increasing, and many who have claims on the tundra, with insufficient water-supply for sluicing, are interested in watching closely the career of the dredges now operating. The Wonder dredge has a considerable area of unfrozen ground, and so long as it has no thawing expenses its success will be

reasonably certain, as the ground is conceded to be of profitable grade under these conditions. If the others, who have the thawing problem to cope with, can operate at a profit it seems reasonable that other dredges will be built for the frozen tundra. A prevalent idea here is to strip off the top stratum of moss and muck, then thaw and dredge the lower strata to and below bedrock. Bedrock-drainage, as a means of draining off the bedrock so as to avoid the expense of pumping, in connection with drift mining, is considered feasible, and some think such drainage will result in increasing the natural thawing process.

Blanck & Ames have a lease on 20 acres, at No. 1 below, McKay beach, on Anvil creek, and in driving from a shaft and doing open-cut work they struck the extension of Pioneer channel, and have good prospects ahead. This is one of the phenomenally rich parts of the district, where the Pioneer Mining Co., under the management of Jafet Lindeberg, has extracted fortunes. In August, this year, that company made a clean-up of \$80,000 at Anvil creek, as the result of 30 days' operations on Moonlight beach; this was taken from the top dirt, and the bedrock stratum has since been worked.

The Miocene Ditch Co. is operating one elevator on Glacier creek, and is operating hydraulic giants on Grass gulch, at the head of Dexter creek. The work of this company is in charge of B. Deleray. The Blue Goose Mining Co. is operating a dredge on Ophir creek, above Council, on ground leased from the Northern Light Co. Their dredge handles only 1000 yd. per day, and works to a depth of 15 to 20 ft., but this is its fifth season.

Gilbert H. Russell is superintendent, and C. B. Phillips represents the Northern Light Co. The Wilson-Kimball Co. has operated a small dredge at No. 24 above, on Ophir creek this season. C. B. Phillips, Stich Bros. & Patton have been placer mining at the head of Crooked creek, a tributary of Ophir, where they have 3 miles of ditch, 2500 ft. of pipe, giving 300-ft. head, by which they operate a giant, running the wash into bedrock sluices, cleaning up 60c. per cu. yd. The Gold Dredge Mining Co., of Seattle, is undertaking a beach-mining enterprise, under the guidance of E. L. Michot, of New York. They have built a heavy barge on the Nome beach, 32 by 70 ft. in size, in the centre of which is an aperture, or wheel, 11 by 40 ft., through which a steel caisson sinks through the barge into the water and sand to bedrock. This caisson is rectangular, 11 by 22 ft., weighs 10,000 lb., and is raised and lowered from a head-frame. On the barge is a 60-hp. tubular boiler, a 30-hp. hoist, and a steam centrifugal pump, as well as sluice-boxes. The idea is to pump the water and sand out of the caisson, as it sinks to bedrock, and sluice it to recover the gold. When bedrock is exposed it is taken up by pick and shovel, and elevated to the sluices. An air-compressor and receiver are provided for supplying air to the workmen while engaged in the caisson. The equipment is to be tried on Nome beach, and then taken to the mouth of Daniels creek, at Topkok.

The Fairhaven Water Co., composed of New York people, is hydraulic mining on the Innachuk river, where it has 41 miles of ditch, carrying 6000 in. of water per second, deriving its supply from Lake Imuruk. The company is operating three hydraulic elevators, taking up 9 to 12 ft. of gravel and 3 ft. of bedrock, the latter being blue lime and schist. A force of 60 men is employed, G. K. McLeod, of Deering, being manager, with R. D. Adams, of Nome, as consulting engineer. It is claimed that the Innachuk river will yield a production of \$250,000 this season.

The Candle-Alaska Hydraulic Mining Co. has 38 miles of ditch in Candle district, bringing a supply of water from the Kiwalik to the Candle creek diggings, where an area 1200 by 300 ft. has been stripped of its overburden to a depth of 20 ft., to give the gold-bearing gravel below a chance to become thawed by the sun's heat. The pay-gravel is 7 ft. deep, worth \$1.35 per yard. T. C. Noyes is president of the company; R. D. Adams, general manager. The production of Nome district proper, this season, will reach about \$3,500,000; and all of Seward Peninsula, including Nome, \$4,000,000, which is one million less than that of 1908.

TORONTO, CANADA.

**Visitors at Cobalt.—Trethewey.—Rochester Mine.—Kerr Lake —
Cement Merger —Conservation Commission.—British Association.**

Next week the Cobalt district will receive a visit from the members of the Ontario Legislature and great preparations are being made to impress the visitors with the growing importance of the mining industry, and the necessity of various local improvements and legal changes. These include a railroad into the Montreal River district to serve Elk Lake, Miller Lake, and Gowganda, and a reduction in the royalties with which many of the Cobalt mines are handicapped. A strong plea will be made for more generous treatment, both in the way of liberal expenditures in the district, and the modification of the royalty system. The camp is having many visitors from a distance, among the latest being a party of Chicago newspaper men under the direction of A. B. Charlson, of the Grand Trunk Publicity Department, and a number of financiers from Indianapolis.

The Trethewey mine is preparing ground for the installation of a concentrator with a capacity of 100 tons per day. No low-grade ore is being shipped, it being reserved for treatment on the ground. It is expected that the concentrator will be ready for operation about the first of next year. At the Coniagas arrangements are progressing rapidly for doubling the capacity of the mill, and the underground work includes prospecting for new veins as well as extensive development on known orebodies. At the North Cobalt an important find was made recently consisting of a blind vein, 20 in. wide, of high-grade ore. It was struck at a depth of 170 ft. The Rochester has exhausted its available funds and the directors have determined on raising the capital from \$1,000,000 to \$1,500,000, the new issue to be disposed of at 10c. per share or better. The shareholders will be asked to ratify their action at a meeting to be held on September 10. The Waldman mine on the Gillies Limit continues to make a good showing. The shaft is being put down with air obtained from the Provincial mine-plant, and at 10 ft. a large vein was found. Over 16,000 ft. of trenching has been done, and numerous traces of silver found in the Keewatin. On the Young and O'Brien adjoining, in addition to the big Waldman vein, a half dozen good-sized stringers have been unearthed in trenching. The Nancy Helen stock had an upward movement this week in consequence of the striking of a 5-in. vein of high-grade ore in driving on the 60-ft. level. At the Martell location adjoining the Waldman a 12-in. calcite and silver vein has been found. A new and apparently important find has been made at the Kerr Lake, where an orebody 4 to 5 in. wide, yielding 3000 oz. silver per ton was found on vein 7 at the 150-ft. level. A well mineralized calcite vein with cobalt has been found in the cross-cut at the 100-ft. level about 70 ft. north of the main shaft. The Townsite, which has been shut down for some months, is again being operated. About 90% of the stock is owned in England. Diamond-drilling will be carried on extensively. The Ophir is sacking good ore at the bottom of the shaft where a big find was recently made, and the shaft is being sunk from 80 to 100 feet.

The big cement merger, including 10 of the principal plants in Canada, has been accomplished. The Canada Cement Co., Ltd., has been incorporated with a capital of \$30,000,000, of which \$11,000,000 is preferred and \$19,000,000 common stock. The present issues, however, will be \$9,000,000 preferred and \$12,500,000 common, and there will also be an issue of \$5,000,000 in bonds. Four million of the preferred stock will go to pay for the properties absorbed. Sir Sandford Fleming, of Ottawa, is president and the provisional directorate consists of Joseph S. Irvin, Senator Edwards, and John R. Booth, of Ottawa; Robert Mackay, Rodolph Forter, and W. M. Aitken, of Montreal, and Francis B. Dunsford, of London, England.

The Canadian Government, in accordance with an act passed at the last session of Parliament, has appointed a

commission for the conservation of national resources, which will act in co-operation with a similar body appointed by the American Government. It comprises 13 ex-officio members, including several Canadian cabinet ministers, and one from each province, and also 20 other members, each Canadian university being represented. Clifford Sifton is chairman, with power to call the commission to meet at any time, but regular annual meetings are fixed for January. The appointment of this body is the outcome of the international conservation conference which met at Washington at the call of Theodore Roosevelt.

The geological section of the British Association at Winnipeg discussed some interesting papers. W. G. Miller was first on the program with his description of Canada's wealth in ores of gold and silver. After briefly sketching the principal geological features of the ore-bearing regions, Mr. Miller hinted that on account of the wide extent of the Laurentian formation other Sudburys and Cobalts would be discovered. Mining in Canada was distinguished not only on account of the rapid increase in the value of the output but also in respect to the variety and scarcity of the minerals. Placer-mining of gold, lode-mining of free-milling gold, and its ores, was briefly mentioned with short descriptions of typical fields or localities. Silver mining in Canada was chiefly associated with the silver-lead ores at Moyle or Slocan, and the interesting Cobalt camp.

The nickel region warranted special examination as one very distinct in its features and relationships. The great 'eruptive well' of the Copper Cliff region and its consideration by Prof. Coleman, afterward led to a discussion as to whether or not this field presented a possible example of an aqueous rather than an igneous ore-genesis. It was suggested in conclusion that Canada should adopt a nickel coinage in place of the present copper one for cent pieces. J. B. Tyrell opened his description of placer-mining in Canada with a short history of the Cariboo, Wild Horse, Cassear, and Klondyke regions. Most attention was directed to the latter as being at present of importance. The geology of this region was described, the area being an unglaciated one which had been subjected to sub-aerial erosion since Miocene times. He estimated that in the Klondyke section 135 cubic miles of solid rock had been eroded with the consequent sedimentation of the mineral content in the valley-bottom. The placers of the Yukon were thus formed rather from exceptional conditions than from a superior mineral content.

MEXICO.

**Floods at Monterey. — Nazas River Controversy. — Wells Fargo. —
Velardena.—Santa Gertrudis Sold.—Pan-American Railroad.—
General Railway Policy.**

The heavy rains during the past week have caused disastrous floods throughout Mexico. The loss of life and property at Monterey has been appalling. Over two thousand persons have lost their lives, and the property-loss has been estimated at \$20,000,000. Railroads are paralyzed, and all means of communication in the flooded districts are temporarily suspended. A number of railroad bridges have been badly damaged or entirely destroyed. The rainfall recorded at Monterey during 72 hours from Friday to Monday totalled 21½ in. Smelter No. 2 has been badly damaged, and the loss to the steel plant must have been considerable, though at present definite news cannot be obtained. It is stated that thousands of tons of coke have been washed away. Monterey has suffered from several bad floods in the past, and this last terrible lesson will surely deter people from re-building on the low-lying lands on the banks of the river.

News also comes from the South of extensive damage to the Pan-American railroad. Over 88 kilometres of the line is tied up, 9 bridges, and sections of the track, totalling 5 kilometres, are reported as washed away. Great damage is also reported along the Gulf Coast, where a severe cyclone has been raging. At Tampico the light-houses on the breakwater were washed away, and the entrance to the

harbor has been so changed that shipping is delayed pending new soundings.

Don Olegario Molina, in his position as Minister of Fomento, has been principally instrumental in making a settlement of the proportioning of the distribution of the water from the Nazas river. Credit is also due to the engineer, Adalberto Hernandez Loyola, who prepared the reports. The basis of the settlement gives to the holders of water-rights on the upper river 64%, and on the lower river 36%, of the available supply. President Diaz has approved and signed the settlement, and this virtually ends the controversy, with the exception of a suit for damages, now pending, brought by the representatives of the Tlahualillo Dams against the Government.

A number of oil-well drillers in Mexico have formed an organization for purely social and benevolent purposes. Over 100 charter members have been enrolled, and it is expected that all of the oil-drillers of Mexico, numbering about 300, will join. Among the officers of the society are C. E. Patchen, president, and H. Hummel, secretary. The first regular meeting of the Mexican Institute of Mining and Metallurgy was held on August 28 at its new office at Tiburcio No. 22. A regular monthly meeting will be held for the reading and discussion of papers, on the last Thursday of each month.

The Wells Fargo company has reached out a long arm and taken a strong hold in Mexico, a merger of the several Mexican express companies with the Wells Fargo having been made under the name of the Compañia Mexicana de Express. One of the important terms of the agreement with the railroad companies is that the express company is to defray all operating expenses, and is to turn over 50% of the gross earnings to the National Railroads.

The Cruz mines, near Valardeña, in the State of Durango, have been the subject of litigation for the past two years; but adjustments have been made, and it seems probable that the original owners will again take possession and open them up. With this object in view an engineer, Manuel Zepeda, has recently been making an investigation. It is expected that the ores will be shipped to the Torreón smelter. These mines were steady producers in the past, and good profits were made.

After all the statements and counter statements, it now seems to be a definitely assured fact that the Camp Bird capitalists will purchase the Santa Gertrudis mine for \$9,000,000. There has been deposited \$200,000 in the Banco Nacional, on a contract signed by Hugh Rose, acting for the purchasers, and Carlos L. de Landero, president of the Santa Gertrudis Co. The terms of the agreement are subject to the approval of a general meeting of stockholders to be called during September. The price equals \$150 for each of the 60,000 shares.

The Pan-American Railroad Co., which started out with the ambition to build a railroad through the length of the American continent, has never been able to obtain sufficient capital to do more than start the enterprise. The latest development regarding this company is that the American Ambassador, David E. Thompson, is negotiating for the purchase of the whole assets of the company. The sale is not an accomplished fact, nor even definitely assured, as some of the minority stockholders are raising questions. The fact that this line is on the market, subject to purchase, and has not been bought in by the Mexican Government merger, reveals something of the policy of the Government toward the further development of railroad enterprise by foreign capital. In discussing the matter with a high Government authority, it was learned that while it is true that the Government had made a merger of the main lines of the country, and controlled them by holding a majority of the stock of the company, yet it was not the desire of the Government, to in any way retard the development of railroad enterprise by foreign capital, or to demand that natives be given the preference of employment on any but the 'merger lines'. The granting of all concessions is, however, dependent on their termination at the end of 99 years, when, under the existing laws, all the permanent way becomes the property of the Government without further compensation, and the Government has the right of the first option for the

purchase of the rolling-stock. The reason for the desire of the Government to control the leading lines is self-evident to any student of national policies. The Mexican is unwilling to allow the exclusive control of finance and operation of the main arteries to remain indefinitely in the hands of aliens. The Mexican Government still continues to grant railroad concessions with exclusive rights, protecting them for a number of years from parallel competing lines, gives exemption from import taxes on material of construction, and in some cases grants subventions per kilometre constructed, but the effect of the general policy and of the existing laws, is that the control of the principal lines is actually in Government hands, and while foreign capital is encouraged under terms and conditions by which it may recoup itself in a few decades, ultimately, within a century, one by one all of the railroads will become national property.

CHIHUAHUA, MEXICO.

Flood Damage at Monterey. — Manta Mining Co. — Acre Mill for Yquivo District. — Smelters Seeking Silica.

During the night of August 27, and the following Saturday and Sunday, Monterey, in the State of Nuevo León, was visited by an excessive rainfall causing one of the most devastating floods yet known in Mexico. The records show that in 1881 there was, however, quite as heavy a flood in Monterey, but there was not then a large population to suffer, and the loss of life and property was not so great. Rain-gauges show that in the three days mentioned there was a fall of 21½ inches of water. This flowing into the Santa Catarina river, usually little more than a dry river-bed, swelled it to proportions estimated as about one-fourth of the Mississippi at flood-stage, and with a velocity of from 20 to 30 miles per hour. People caught in their homes sought the roofs, expecting the waters soon to subside, but they did not, and the houses being made of adobe soon softened and crumbled and the unfortunates were swallowed up in the seething waters. Thus went groups of 10 and 20 and with one of the school buildings something like 90 that had sought refuge there. It is estimated that fully 2000 people were lost. Over 1000 bodies have already been recovered. Property has been destroyed and damaged to the extent of nearly \$20,000,000, and the loss to the railroads reaches into the millions, the heaviest they have known, and covering the section all around Monterey and for a great distance down toward Tampico, as the railroad and the river follow the same course for many miles. The Santa Catarina river flows along the entire southern border of the City of Monterey, a district inhabited almost wholly by the poorer classes, so that the wealthier suffered but little except through loss of property in the inundated area. Along with the railroads the greatest losers were the smelters situated in the southeastern portion of the city. The Monterey plant of the American Smelting & Refining Co., though rather low, is to the north of the town, some miles from the river, so that it suffered only the natural discomforts of a heavy local rainfall, but at the plants of the Monterey Mining, Smelting & Refining Co., and of the Monterey Iron & Steel Co., the loss was great. That of the Monterey M. S. & R. Co. is said to be close to \$1,000,000. At the steel plant the loss of the coke washed away will exceed \$1,000,000. With other losses to plant and supplies the total estimate for this concern is about \$2,000,000. This is probably more than it can stand. In a considerable flood of but two weeks before it suffered a loss of close to half a million pesos, and for several years it has not been in a flourishing financial condition. It is feared that it may not be able to recover from the present terrible blow.

From Chihuahua most favorable reports continue to be received. At Santa Eulalia the new Manta Mining Co., Ltd., recently mentioned in these columns, operating on the Carmen-Negrita group has found a rich body of lead-silver ore at a depth of but 150 ft. in its new shaft on the Carmen. The Qualey Bros., who within the last few months have resumed development on the Parcionera in Santa Eulalia, have opened a body of good grade lead ore, their previous

product having always been low-grade silver-manganese ore. They expect to resume shipments before the end of the year. At the Qualey's San Francisco mine, in the Yoquilvo district of western Chihuahua, the mill is in course of construction; the first unit will consist of 10 stamps, with tube-mills and air-agitated cyanide tanks. The success of cyanidation throughout Mexico in the treatment of the clean silicious ores has made a great cut in the supply of that character of ore for the smelters, and several of the smelting companies have had to commence mining silicious ores for themselves in order to obtain the necessary supply for flux. Following the lead of the Torreón Metallurgical Co., the Santa Rosalia smelter (which is still running, to the marvel of all who know of the stock-jobbery connected with it) has taken up through its agent, P. Gaudin, several mines in the Parral and Santa Barbara districts and expects to be soon producing its own silicious ores. With the same object in view the Peñoles Mining Co., for its Mapimí smelter, after vainly attempting to contract for ores going to the American Smelting & Refining Co., has taken up the Perla, near Revanche, the Resolana, near the Palmilla, and the Dewey, of Ronesvalles, all tributary to Parral, and will immediately begin working them for the silicious ores.

NEW YORK.

Ohio Copper Sold. — Mascotte Tunnel. — Santa Gertrudis. — Tennessee Copper Bonds.

The International Smelting Corporation will shortly be in a position to announce its ownership of the Ohio Copper mine, in Utah. There is good reason to believe that the International Smelting Corporation now controls the Ohio mine and that Messrs. Cole and Ryan are negotiating with Heinze for the purchase of the Mascotte tunnel which cuts the lower levels in the Ohio property. The tunnel is privately owned by Heinze, and the only way the International Smelting Corporation can obtain it is by purchase. Heinze has been offered a tempting sum for it, and has reason to believe that many of the legal difficulties in which he is involved will be lightened and straightened if he will sell the tunnel. He has had a long conference with representatives of Cole and Ryan, and the International Smelting Co., and as the control of the Ohio mine has been taken away from him, it is probable that he will sell the tunnel. Heinze still has control of the Davis-Daly mine, and will concentrate his efforts to keep it.

The district attorney is still investigating the Ohio-Davis-Daly stock thefts, and the directors of the Windsor Trust company are having a private investigation made of the Trust's connections with the frauds. Little is expected to result from these investigations. George W. Perkins, of J. P. Morgan & Co., has returned from an inspection of the Yukon Gold Co.'s properties, and will at once set about making arrangements for starting a boom on the company's shares on the New York Curb market. The returns from the alluvial workings this summer have been so satisfactory that the directors will be in a position to declare a dividend of 8%. It will be remembered that large blocks of the company's stock were sold to the public at \$9 per share by Thomas W. Lawson, on behalf of the Guggenheims, who formerly owned the properties. As soon as Lawson's advertising campaign ended the stock value gradually receded to \$3. The stock is now quoted at \$5 per share. Some months ago Thomas W. Lawson was engaged in an active copper stock campaign on the Boston and New York curbs. Notwithstanding his costly advertising and press notices the public failed to heed the virtues of his numerous copper properties.

Trinity and other stocks Lawson is interested in remained heavy and he is understood to have taken heavy losses. Activity is again being shown by his stocks and another campaign is reported to be brewing. Brokers who do business with Lawson state that he has re-couped his losses. When the Harriman pool ran the preferred and common stocks of the Union Pacific railroad up to their recent record prices, Lawson is believed to have gone heavily short of both issues, and during the decline sold so advan-

tageously that his profits closely approximated those made by Mr. Harriman.

Advices from the owners of the Santa Gertrudis mine, Pachuca, Mexico, state that John Hays Hammond, acting on behalf of an English company, has purchased that property. Hammond has had an option on the mine during the past three months. His report is said to have been confirmed by those of two well known mining engineers. Hammond recently purchased La Blanca mine, Pachuca, for the Camp Bird directors. The directors of the Tennessee Copper Co. have arranged for the sale of short-term notes amounting to \$600,000. Part of this loan will be used for development, and the balance will be employed in doubling the capacity of the sulphuric acid plant. The company is a member of the fertilizer trust and has entered into large contracts to furnish the trust with acid.

BUTTE, MONTANA.

Gold Dredging in Montana.—Results at Conrey. — Testing German Gulch.

The Tuolumne Mining Co. has begun shipping ore from the new level of the Tuolumne mine at a depth of 1400 ft., but the shipments do not exceed 100 tons per day. The mine is not sufficiently opened and the capacity of the plant is not large enough for a heavy production. An industry of constantly growing importance in Montana is gold dredging, and men and companies interested are searching the State for good placer properties. The results of dredging by the Conrey placer company at Alder, Montana, are attracting capital. The Conrey people and representatives from the California companies have been in Butte during the past week to investigate placers in the vicinity of this city. The Conrey company has been making examinations and tests in Elk Park, near the Great Northern railway, and a representative of a big California company has been examining ground west of the city and another tract in Powell county. The Conrey company started about ten years ago with one steam dredge, on some land at the mouth of the famous old Alder gulch, near Ruby. It was so successful that it gradually acquired several thousand acres of adjacent farm land. The company has now three big dredges working, electricity having been substituted for steam, and it has worked about 200 acres to an average depth of 30 ft., the deepest point to bedrock being 60 ft. The ground yields an average of 20c. per cu. yd., and the three dredges turn out \$35,000 per month the year round. The gold brings \$17.50 per ounce. The gulch has a width of about 600 ft., but the gravel deposit is rather shallow. There is also a good placer near Woodville, the first station on the Great Northern east of Butte, from which considerable gold has been mined, and it is likely that explorations and tests will be made there in the interest of a new dredging proposition. Attention has also been directed to the old placers of German gulch, west of Butte. It is estimated that no less than \$40,000,000 in gold have been taken from German gulch, and the belief is that the deposits ought to be as good as those at the mouth of Alder gulch, though less extensive.

ROSSLAND, BRITISH COLUMBIA.

Diamond Drilling at Le Roi.—Nickel Plate.—Kingston G. & C. Mining Co.—United Mine, Ainsworth.

A contract has been let for the first lot of diamond-drill work to be done in the Le Roi mine at Rossland. The work has been awarded to O. L. Knight & Co., and will keep three diamond-drills in steady operation for the next six months. The hitherto rich South vein will be pierced with diamond-drill holes at intervals of about 100 ft. apart in an effort to find further bodies of ore similar to the lenticular body of \$100 gold-ore opened on the 1650-ft. level some time ago.

At the Centre Star group, the week's shipments were up to standard. The company has begun diamond-drill ex-

ploration of its Enterprise claim. It is said that if work on this claim proves promising, the Consolidated will acquire several adjacent claims, which, from the surface showings, appear to contain big bodies of ore. The surface showings contain extensive low-grade deposits. On the Hattie Brown, in the South Belt development, work still goes on. It is planned to do a lot of diamond-drill work very soon.

It looks as though the dissenting shareholders of the Dominion, at Phenix, would stir up trouble for the recent purchasers of the interests of the old company, if there is any legal way. B. W. Lincoln, of New York, representing nearly \$300,000 in stock and bonds of the old company, looked over the property of the company here last week, stating that this was part of his plan toward working out the program of the shareholders' protective committee. From this district Mr. Lincoln went to Vancouver where he will look into the matter of the sale of the property. It is now reported that the B. C. Copper has acquired a \$500,000 interest in the New Dominion Copper Co., and that a merger has practically been settled upon, the final details only remaining to be arranged. The Mother Lode mine of the B. C. Copper Co. shipped 6840 tons of ore to the Greenwood smelter during the past week; two furnaces are working at the B. C. Copper smelter, and the other one is being enlarged. The shipments from the Snowshoe mine made another record for the past week, the company shipping 4430 tons.

A million-dollar deal has been consummated for the famous Nickel Plate gold mine at Hedley. The affair has been managed by M. K. Rodgers, a mining man of note in this district, and who first brought the Nickel Plate to the attention of the late Marcus Daly. While there is a good tramway and mining plant, also a 40-stamp mill on the ground, it is said the new owners will install a much larger mining and milling plant, and will work the property on a larger scale than heretofore. Now that the V. V. & E. railway has its tracks laid into Hedley, mining in that vicinity will receive an impetus. The Nickel Plate mine has been bought by the Exploration syndicate, said to be strongly backed by Standard Oil and United States Steel capitalists; Frank A. Ross, who has been manager for the last several years, will remain in that capacity with the new concern. Work is being steadily continued on the property of the Kingston G. & C. Mining Co., and it is thought that the work has now led to the line where the prospect changes to the mine-stage.

The United mine, near Ainsworth, has been acquired by J. S. Airheart, now in charge of the Highland and Buckeye properties in the same district. The Highland concentrator is quite large enough to handle the present output of all three mines, so that the ore from the United will be treated there. Shipments have begun from the Highland and Buckeye at the rate of 20 to 25 tons per week. G. B. Squires, lately with the American Mining & Smelting Co. has been placed in charge of the Highland-Buckeye-United group. An addition to the Highland mill is planned by Mr. Airheart. A new lead has been opened up in the Mother Lode mine, Sheep Creek camp, from which samples have been taken assaying over \$400 per ton in gold. The strike was made on the 300-ft. level of the mine, and occurs in a 4-ft. shoot of ore that has been driven upon for some distance.

SALT LAKE, UTAH.

Big Tunnel for Bingham — Silver King Deposits. — International Smelter.—Park City Tunnel.

One of the most interesting propositions that confronts the mine operators of Bingham is the driving of a tunnel that will serve the purpose of every mining property in that camp. The Mascotte tunnel, which is owned by F. Augustus Heinze, has been extended into the mountain from the Salt Lake valley side of the range, over 13,000 ft. to the end-lines of the Utah Copper. This in part solves the problem that confronts the big mines of that district, and in it some interesting disclosures of ore deposits have been made. This channel also affords the cheapest means of transportation in the entire camp, and drains a large

area of ground that could not otherwise be economically mined. As a result of the development in this tunnel it has dawned upon eminent mining engineers that there is a large acreage of mineral-bearing territory that can best be developed in this manner, and that in addition to providing cheap transportation a large territory will be drained and the water will be of value for power, and for the mills and smelters. Engineers have been studying the situation carefully, and plans are shaping so that some large capitalists and mine-owners are to become interested in the project. By extending this channel to the Pine canyon side of the range, such producers as the Utah Copper, Boston Con., Yampa, Utah Con., and a number of others will not only be tapped to considerable depth, but a more economical means of transporting the product will be provided. In the case of the Utah Con., they are already experiencing difficulty with water. The deepest working is down 900 ft., and at this depth they have an immense tonnage of the high-grade ore. This company is pumping and has been for some time. Within a few years a number of other operators in Bingham will experience the same difficulty. It is estimated that the extension of the Mascotte tunnel through the district to an outlet on the Pine canyon side of the range will require 16,000 to 18,000 ft. of driving. The engineers of the various property-owners in the camp have held a number of conferences, and an effort has been made to get each company to share in the work. No arrangement has been concluded, but it is learned that every mine-owner sees the importance of it, and in a measure appreciates the value to the camp of the opening up of such a channel.

A survey has just been completed by the Silver King Coalition Mines Co., engineers of the underground workings of that bonanza in Park City. The development done by this company amounts to 75 miles. Since mining was first started in this property, about 20 years ago, there has been extracted \$25,000,000 worth of ore. There are large ore deposits being opened each year, and one of the engineers estimates that they have ore enough blocked to keep the mine producing at its present rate for 40 years more. Its dividends to date amount to approximately \$12,000,000, and it is distributing profits at the rate of \$750,000 annually, with an extra payment during the holidays, that places the amount at \$1,000,000. The product is a silver-lead ore, and some of this carries gold and copper in paying quantities. The first-class product averages about \$45 per ton, and there is barely enough second-class ore to keep a mill of 150-ton capacity in operation. Active construction is being carried on at the International smelter. Some of the largest buildings, including the power-house, machine-shops, warehouse, and store-rooms are nearing completion. The foundation for the mammoth stack, which is to be 350 ft. in height, is laid. Additional engineers and workmen are being placed on the work, and the management expects to have its bins completed and ready to receive ores by the first of the year. Two of the blast-furnaces will be prepared for blowing-in simultaneously, and enough ore will be on hand from the Utah Con. to start smelting before the contract with that mine goes into effect on April 1, 1910. It is understood that ore from the Giroux mine, at Ely, will be forwarded to this plant until the Giroux smelter is constructed. The Ohio Copper and several other large producers, will also be ready with concentrate by the time the smelter is fully commissioned.

A tunnel is to be driven from the Snake creek side of the Park City district to tap the ore-channel in the Bonanza Flat country. This channel is also to be extended into the Daly-Judge group, and will cut that property below its present workings. The tunnel will be of great advantage to the Daly-Judge, as it will drain its immense territory at considerable depth. It will also be the means of opening up some virgin ground and give other owners of ground in that vicinity an opportunity to work their properties, which they have been prevented from doing by reason of the great amount of water in that portion of the district. Almost all the property-owners will take stock in a company that has been formed for the purpose of driving this tunnel.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Reheating compressed air increases efficiency through increase in volume. There is always loss of heat between the re-heater and the point of application of the air, so that pipe-covering to prevent radiation and loss of temperature is important. It is easy to increase the temperature of the air about 400° F. in passing it through coils in a heater at the rate at which it would be needed for medium-sized mine-pumps. The loss between the heater and the pump might amount to as much as 100°, making an effective increase of 300. In such case, when the air entering the heater was at normal temperature, the increase in volume effected by the re-heating would be about 40%, but the practical net efficiency would only amount to about half as much.

Treatment of zinc ore at Austinville, Virginia, which has averaged about 30% of that metal, and from 8 to 10% lead, has been to reduce in Blake crushers and then in corrugated rolls to 6 m. m. diam., concentrating in log-washers, and in jigs. No re-crushing of tailing is practised. The Wetherill magnetic separator is employed to eliminate the iron-bearing minerals. The capacity of the plant is 90 tons per diem of 10 hours. In addition to the smelting plant for concentrate a zinc-oxide plant has been installed for treating the low-grade ore and tailing, the average content being from 15 to 20% zinc. The oxide produced contains 4% lead and from 70 to 80% zinc. This is sent to the furnace for making into spelter.

Zinc ores in Virginia occur in the earlier horizons (Cambrian to Carboniferous) and are distributed in the Great valley region, including Roanoke, Botetourt, Montgomery, Pulaski, Wythe, Smythe and Russell counties, and also in the Piedmont region of crystalline rocks in Albemarle county. The principal production has been from the Bertha mines, near Austinville, Wythe county. For many years the zinc was produced entirely from the secondary or oxidized ores, and the spelter was of such exceptional purity as to give to this brand a world-wide reputation. Latterly the lower sulphide ores have been developed, which are found to be disseminated through brecciated limestone. The magnesian limestone has been replaced in part by zinc and lead sulphides and by calcite.

Lead-smelting in home-made furnaces is frequently practised, and is often an advantageous way for an isolated mine with rich ore to make a start. It is, of course, wasteful of metal, of fuel, and of labor, and leaves residues which contain much lead and silver, when the latter is present in important amount. The ore-hearth is one of the favorite furnaces for this kind of work, and requires comparatively little skill. A description of such an appliance and the mode of operating it, cannot well be condensed within the limits of a concentrate. Essentially it is a deep forge, with one or more tuyeres

or blast-inlets at the back, which is closed with a wall, the blast being deflected downward. The front of the hearth has an apron on which the operator works to break up sintered masses in the charge. The sloping-hearth reverberatory furnace (Bleiberg type), is preferable with very rich ores, as it leaves cleaner residues, and requires but little more skill than the ore-hearth.

Sand in launders should move at a velocity of about one-half that of the transporting current for maximum efficiency. The diameters of bodies which can be moved by a current vary as the square of its velocity, and their weights as the sixth power of the velocity. As the weight of sand immersed in water is less than in air, according to the respective specific gravities of the particles, they are relatively more easy to move than their absolute weight would indicate. Quartz pebbles 1 in. diam. will roll along a channel when the current-velocity is 3½ ft. per second. A common cause of trouble with the clogging of launders is in the preponderance of relatively flat grains, which are not amenable to the laws applicable to bodies of approximately spherical form. Launders are frequently made too narrow. The width should be greater than the depth.

Residual gold-deposits is a term used to express a distinction which is often more a matter of degree than of kind, that is, the term becomes applicable only when the amount of such material is large enough to be of economic importance. Except in situations where rapid erosion occurs almost all gold veins leave a decomposed, enriched superficial zone. This has been variously termed 'residual', 'rooted deposit', and 'saprolite' or rottenstone, the latter originating in connection with the southern Appalachian deposits where they are quite characteristic, often simulating the appearance of placers, and actually become lines of drainage. Thus in the Carolinas it is not uncommon to find creeks following the courses of veins. Some of these residual deposits were extremely rich. Similar deposits are found in Brazil, and a great area of rich saprolites is said to exist in the upper drainage of the Rio Beni in Bolivia.

Cupola practice for melting iron admits of wide variation, dependent upon the size of furnace, character of fuel, and other conditions. Foundry furnaces are made in sizes from 22 to 72 in. diam., inside, at the tuyeres. The smallest size will have a capacity of 1000 to 1200 lb. of pig iron melted per hour, and will require a blast-pressure of about 6 oz. This may easily be supplied by a blower. If charcoal be used for fuel a still lighter pressure will be required. The average economical size of cupola for foundry-work measures 36 in. diam. at the tuyeres. Such a furnace would require about 1 ton of fuel for an ordinary melt, lasting two hours, and would in that period turn out about 7 tons of iron. This would require a blast pressure of 8 oz., and a blast-pipe 12 in. diam. Each charge in such a 'heat' would consist of about 3000 lb. iron, 150 lb. coal, and 75 lb. coke, starting on an original fuel-bed of 1000 lb. coal.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Aliens' Rights in Mining Claims.

The Editor:

Sir—Knowing that you are in touch with the decisions that interpret the mining laws of the United States, and as most of my work has been done in foreign countries, I would be your debtor if you would answer, through the columns of the MINING AND SCIENTIFIC PRESS, and give me your idea of the legal phase of the following case.

Referring to Section 2319 of the United States mining law, there is found this statement: "All valuable mineral deposits * * * by citizens of the United States and those who have declared their intention to become such, etc."; bearing this in mind, suppose that Juan Silva, a man born in Mexico, and residing in the State of California, but who has not taken out papers of naturalization as an American citizen nor in any way has taken steps to that end, has located a lode claim, and held the same by virtue of doing annual assessment work for five years. He offers the same for sale, and the prospective purchaser, finding that said Silva is not a citizen of this country, re-locates the claim. (1) Can the jumper bring suit against the Mexican to quiet title, successfully? (2) Can the Mexican, by starting proceedings for his naturalization, legally dispossess the jumper? In short, what is your understanding of the legal status of the case?

H. B. KAEDING.

Los Angeles, California, August 29.

[The situation is well set forth in Lindley on Mines, as follows (Section 234): "We think that the decision by the Supreme Court of the United States in McKinley M. Co. v. Alaska United M. Co., to the effect that a location by an alien is free from attack except by the Government, establishes the law that no rights may be initiated by a citizen through a re-location of the ground appropriated by an alien, until the latter's title has been determined by the Government. Prior to that time the ground would not be open to location or re-location. One attempting to re-locate the ground could not connect himself with the Government title, and would acquire no rights whatever. If he should institute an adverse suit based upon such pretended re-location he might assist the Government in preventing the alien from securing a patent, but such a result would not validate his pretended location."

The rights of the alien are thus stated in Costigan on Mining Law (p. 167: "Whatever may have been the intention of the framers of the act of 1872 (Act May 10, 1872, c. 152, 3, 17 Stat. 91; U. S. Comp. St. 1901, p. 1425), with reference to the point, it is now well settled that a location by an alien or the transfer of an existing location to him is valid except against direct attack by the Government while the alien still owns the land, or except when ques-

tioned in an adverse suit where the alien is applying for patent or is adversing."

An alien may locate a mining claim and hold and operate the same indefinitely unless the Government should institute proceedings known as 'office found', but the alien may not proceed to patent. The validity of tenure is recognized, but the title is nevertheless imperfect. This defect is cured by transfer to a citizen, who may then proceed to patent. On the other hand if an alien acquires an unpatented mining claim which has been located by a citizen the alien may not obtain patent. This shows that in the view of the courts the defect lies solely in the disability of the alien to obtain confirmation of title by United States patent.—Editor].

Locating Placer Claims.

The Editor:

Sir—Your article on placer mining locations forming a part of 'Concentrates' in your issue of August 28 conveys the impression, (1) that a person may acquire title to placer mining ground by collusion with the locators, and (2) that a placer location may, legally, be in any form convenient to its locators. This, in my opinion, is against law.

The purpose of the mining Act in limiting a placer location to 20 acres in the case of an individual, and to 160 acres in the case of an association of eight persons, is to prevent, as far as possible, the acquirement of large tracts of placer-ground by a single individual through location. It is axiomatic that what may not be done directly cannot legally be done indirectly. Hence, while one may locate as many separate 20-acre tracts contiguous or otherwise as he may elect, he cannot use his friends or employees in making a location of 160 acres with the understanding that they shall transfer the same to him without consideration, and thus permit him to acquire more land in a single location than he is entitled to as a locator under the provisions of the mining law. The courts uniformly hold that such a transaction is void, and that the location is invalid to a greater extent than the maximum limit which an individual may locate, namely, 20 acres. Of course, any person, firm, or corporation may acquire by bona fide purchase the interest of his or its co-locators or of others, to an unlimited extent.

Placer locations, whether upon surveyed or unsurveyed lands, must conform as near as practicable with the United States system of public land surveys, and the rectangular subdivisions of such surveys, except where such placing of the lines would create a conflict or overlap upon other prior-located claims, or where the land sought to be located is surrounded by prior locations.

The Land Department holds that entries of the mineral lands should be as compact and regular in form as reasonably practicable, and that it will not permit or sanction entries or locations which cut the public domain into long narrow strips or into grossly irregular or fantastically shaped tracts. It lays down the rule that "where a placer location by one or two persons can be entirely included within a square 40-acre tract, by three or four persons within three square 40-acre tracts, and by seven or eight persons

within four square 40-acre tracts, such locations will be regarded as within the requirements where strict conformity is impracticable" (Mining Regulations, par. 30, approved March 29, 1909. See also Snow Flake Fraction Placer, 37 L. P. 250). Ten-acre tracts are dealt with as legal subdivisions, and under the regulations of the Land Department they "may be described, for instance, as situated in the extreme northeast of the section as the N. E. $\frac{1}{4}$ of the N. E. $\frac{1}{4}$ of the N. E. $\frac{1}{4}$ of the section, or, in like manner by appropriate terms, wherever situated."

In other words, a placer location should be rectangular in form, compact, and with east and west, and north and south bounding lines. Whether a placer claim conforms sufficiently is a question of fact to be determined by the Land Office. Each case must be determined in the light of its own facts. It follows that it was an error to state that "the grouping of the eight claims in one association-claim may be according to the desire of the locators."

In conclusion, permit me to say that in my opinion the only legal way to acquire any part of the 'unlimited vacant ground' you speak of is by the 'deed holder' locating the same in one or more separate 20-acre tracts and consolidating the same with the tract now held by him, or by abandoning the original location to the Government and re-locating with seven others who would thus become his co-tenants therein. Of course, if the original or subsequent transfer is collusive, the claim might be reduced to an area of 20 acres.

A. H. RICKETTS.

San Francisco, September 1.

Assessment Work on Placer Claims.

The Editor:

Sir—In a book entitled 'Hydraulic and Placer Mining', by E. B. Wilson, I find the following statement on page 275: "Congress requires no annual expenditures on placer claims, leaving them subject to the local laws, rules, regulations, and customs of the mining district." May I request you to confirm this statement, as it is my belief that it is not true. I have in mind the locating of some placer claims on which no actual recovery of gold in commercial quantities has ever been made, but which have been held for two or more years by a very limited amount of trenching. The dates of some of the location notices are as far back as 1902. According to Wilson's statement perpetual title to such claims is obtained by the mere act of location. The Territorial laws make no provision for annual work, but state that "the size and the amount of annual assessment work to hold possession and acquire patent shall be the same as provided by the Revised Statutes of the United States."

PAUL J. CASE.

Leopold, New Mexico, August 25.

[The quotation from E. B. Wilson's 'Hydraulic and Placer Mining' is correct to the extent that no specific mention of annual assessment work on placer claims is made in the Statutes. The Act under which assessment work is made obligatory referred to lode claims, but the courts have held that it was intended to cover mining claims of every sort, and many decisions, both by the lower courts and by the

Supreme Court, have established the requirement as applying to placer claims as fully as to lode claims. Hence it is imperative as a condition of tenure to perform \$100 worth of work annually upon each individual or association-claim.—EDITOR.]

Mine Surveying Hints.

The Editor:

Sir—I read with interest H. H. Holbert's letter on 'Mine Surveying Hints', in your issue of May 15, because I have been 'up against' the same problem which he describes in his letter. Transferring the meridian from the surface to the underground workings through a vertical shaft of 1600 ft. and over is one of the most trying problems the mine surveyor meets, especially if the shaft is a wet one. I have tried a number of methods for taking the meridian underground, by triangulation, and otherwise, but I believe with proper care the best results can be ob-

tained with the method mentioned by Mr. Holbert. This is a scheme often employed in the Transvaal deep-level shafts.

The principle of the method I use is the same as that described by Mr. Holbert, but the details are different. After suspending the two wires down the shaft, the instrument is set up about in line with the wires, at the level in the mine where the meridian is desired. Then the point of rest of each oscillating wire, A and B, is determined separately, as follows: A scale is made of sufficient length, say one foot, on a piece of tracing cloth, the divisions being as small as $\frac{1}{32}$ of an inch, the lines being made fairly heavy, with water-proof India ink. This tracing-cloth is then stretched across the open side of a box, and a small lamp or candle is placed inside the box, a hole of sufficient size being cut in the top to prevent the wood catching fire. The illuminated tracing-cloth is placed behind the wire, on a plank stretched across the shaft, and put as near as possible to the wire, and the oscillations noted. So well does the flame il-

illuminate the scale on the tracing-cloth that the divisions are readily seen with the telescope, and an accurate and speedy determination of the point of rest is obtained. The wire is drawn aside, a pin *a*, being driven into the board, to mark the point of rest. The same thing is done with the wire B, the point of rest being marked with a pin *b*.

The instrument is now brought exactly in line with the points *a* and *b*, and the line thrown forward in the cross-cut to 1 and 2. If ten such determinations are carefully made, and the average taken, this method is, I think, as accurate as any. It is a quick one as well.

The surveyor of a 'deep-level' mine in the Transvaal generally uses this method to get a connection between the two vertical shafts. After the first connection is made, he frequently carries his meridian underground by means of the 'one wire in each shaft method' (See Brough's 'Treatise on Mine Surveying', page 208), especially if there is a discrepancy of a few minutes when the tie is made through the connection. Where the boundary lines underground have to be determined with the accuracy necessary in the Transvaal, too great care cannot be taken in carrying the meridian below ground. This is the starting point of the underground surveying, and all the accuracy in the world in subsequent work will not make up for an error in taking the meridian underground.

T. LANE CARTER.

Ocongwas, Nicaragua, June 29.

Rejection of the Yard Mining Claims.

The Editor:

Sir—The decision rendered by the Department of the Interior, July 3, 1909, in the case of H. H. Yard, etc., raises a question of considerable interest and importance. The following language was used by the Assistant Secretary in deciding the case; though it was not essential to support the decision, there being other reasons given as the main basis of the opinion:

"So far as the evidence shows, no discovery of mineral was made prior to the making of the 'paper' locations, that is, the posting and recording of the notices of location. These claims, in the majority of instances, were transferred either to H. H. Yard or to the North California Mining Company, a corporation. The appellants maintain that, even if no discovery was made before the locations, any subsequent discovery operated to validate the claims. Such alleged subsequent discoveries occurred as is shown by the evidence, during the spring and summer of 1907, and at a time when the asserted locations were claimed and owned either by Yard or the company. Does a discovery under such circumstances serve to validate a claim of 160 acres? It is conceded that a single discovery upon a maximum placer location held by eight persons is primarily sufficient to sustain the location, but the eight associated persons are absolutely essential to the initiation and completion of such a location. When an asserted placer claim of 160 acres, which is invalid, being without a discovery, is transferred to a single individual, it is inconceivable that he alone can perfect

such a location by making a subsequent discovery, seven associates being necessary to initiate and perfect a valid location thereof. The same situation arises as to a claim of maximum area held by a corporation which is in legal contemplation an entity, in which all property rights under the location are vested, the individual shareholders not being co-owners with the corporation or with each other in the corporate property. Repeater and other lode claims (35 L. D. 54). In the opinion of the Department there is no basis for the theory that a subsequent discovery works the validation of a placer claim where the area of the claim exceeds that which the then holders can locate in the first instance. The contrary doctrine would not be within the purview of the statute, but entirely beyond its scope, and unauthorized."

A similar situation arose in the case of *Miller v. Chrisman*, 140 Cal. 440. There the Supreme Court of California, sitting in bank, expressly decided, under similar circumstances where an association-claim of 160 acres had been located and prior to discovery the seven co-locators had conveyed to the eighth associate, who thereafter made a discovery, that the inchoate rights existing prior to discovery were "the subject of conveyance by the associates as well before as after discovery", and the claim was held valid in its entirety. The court said, "We can perceive no reason why the right to prosecute the work and perfect such a location by discovery may not itself be vested in a single one of them."

This judgment was affirmed by the Supreme Court of the United States in *Chrisman v. Miller*, 197 U. S. 313, and while the Federal Court did not comment on this particular phase of the case in its opinion, the judgment of the State Court could hardly have been upheld without affirming the holding made below on this very question. It will be interesting to see whether the Land Department will maintain the position taken in the Yard decision when the question is again squarely presented to it for determination. The matter is of considerable importance in view of the fact that since the final decision in the *Miller-Chrisman* case, it has been the almost universal custom in the oilfields for locators of an association-claim to convey to an individual, usually a corporation, prior to any discovery of oil being made.

WM. E. COLBY.

San Francisco, September 2.

Copper-titanium is valuable for copper castings. Copper, when melting, absorbs gases and is oxidized, to a certain extent during fusion, the oxides dissolving in the metal, with the result that copper cannot be cast in sand directly from the crucible. Auguste J. Rossi, the pioneer of titanium, recommends the addition to the copper of from 1 to 2% of combined cupric and titanic material, for example, an alloy of copper and titanium containing from 5 to 12% of titanium. This alloy is used to the extent of 1 to 2% of the entire weight of copper. Copper treated in this way can be cast in sand, the pouring being quiet, without overflow through the gates, and without piping, and the resulting bars, presenting a close grained, dense structure, free from blow-holes.

THE SOUTHERN ARIZONA COPPER FIELDS.

Written for the MINING AND SCIENTIFIC PRESS
By C. F. TOLMAN, JR.

The data for this paper were collected during a recent visit to Bisbee, Morenci-Metcalf, Globe, Miami-Inspiration, and the Ray camps. They serve for giving a simple description of the ore occurrences and their relation to the local geology, and for a summary of the changes in mining operations that have been made in response to the continued low price of copper. Bisbee, Morenci-Metcalf, and Globe have received careful attention from the United States Geological Survey, and the unraveling of the broader details of the geology by the Government scientists has made possible the detailed geological work that is now being carried on by many of the companies. This work, however, was done some time ago, and for these camps, the attempt is to summarize the critical structural features, and bring out what modifications are now suggested by the later developments.

The new class of deposits recently disclosed in Arizona, namely, the disseminated chalcocite deposits in schist, promises such economic importance that both their novelty and magnitude give interest to any information concerning them. The deposits of the Silverbell camp have, as yet, received no geological description. They present many novel features. Not only are they of considerable economic importance today, but they promise increased production. A short summary of the most interesting points in the geology is taken from notes made during various visits to the camp.

Other important or promising camps in this great copper region, such as Ajo, Courtland-Gleeson, Johnston, Twin Buttes, and Helvetia, present interesting geological relations worthy of careful study and description. The Arizona-Sonora copper fields are not along any straight belt or belts, as has been portrayed in various prospectuses. I have seen outlined two parallel belts, and also two belts at right angles, and in one case two diagonal belts, the crossing of which was made at the properties described. The extensive development of copper deposits in the southeastern part of the territory is, of course, directly related to the geological structure. The northern part of the territory is a vast plateau, covered by formations that are in general later than the period of copper mineralization. This plateau is broken into massive fault-blocks, but lacks the post-Paleozoic intrusions to which the deposition of the copper ore is due. For some distance south of the great escarpment that bounds this plateau region, the formations consist largely of volcanic outpourings, that will always hide, as far as human occupation is concerned, the possible underlying copper deposits. The interesting Gila conglomerate, extensively developed in the main drainage basins of the copper region, is contemporaneous in part with the volcanic formations. Fortunately this covering has been largely swept off the foot-hills, and never covered the mountains so that there is probably not a great loss of mineral area under this deposit.

As shown on the sketch (Fig. 2), the copper

region covers southeastern Arizona and extends into Sonora. The boundaries are not, of course, hard and fast lines, and may be extended with the more careful prospecting of the region. It is an area from which the later formations have been in part or largely removed. The Paleozoic series of quartzites and limestones, often with the underlying 'Pinal schist', appear in the mountains, which frequently show the monoclinical structure, as a uniformly dipping checkerboard of small fault blocks. The acid granitic intrusions are the indispensable factors, and the copper deposits are found in certain restricted areas, near the contact that marks the margin of the intrusion. As there seems to be no regularity in the distribution of these intrusions, there is still less in regard to the deposits themselves. Walter Harvey Weed has discovered (1) that the Schultze granite, classed provisionally by F. L. Ransome as pre-Cambrian, is really post-Paleozoic,

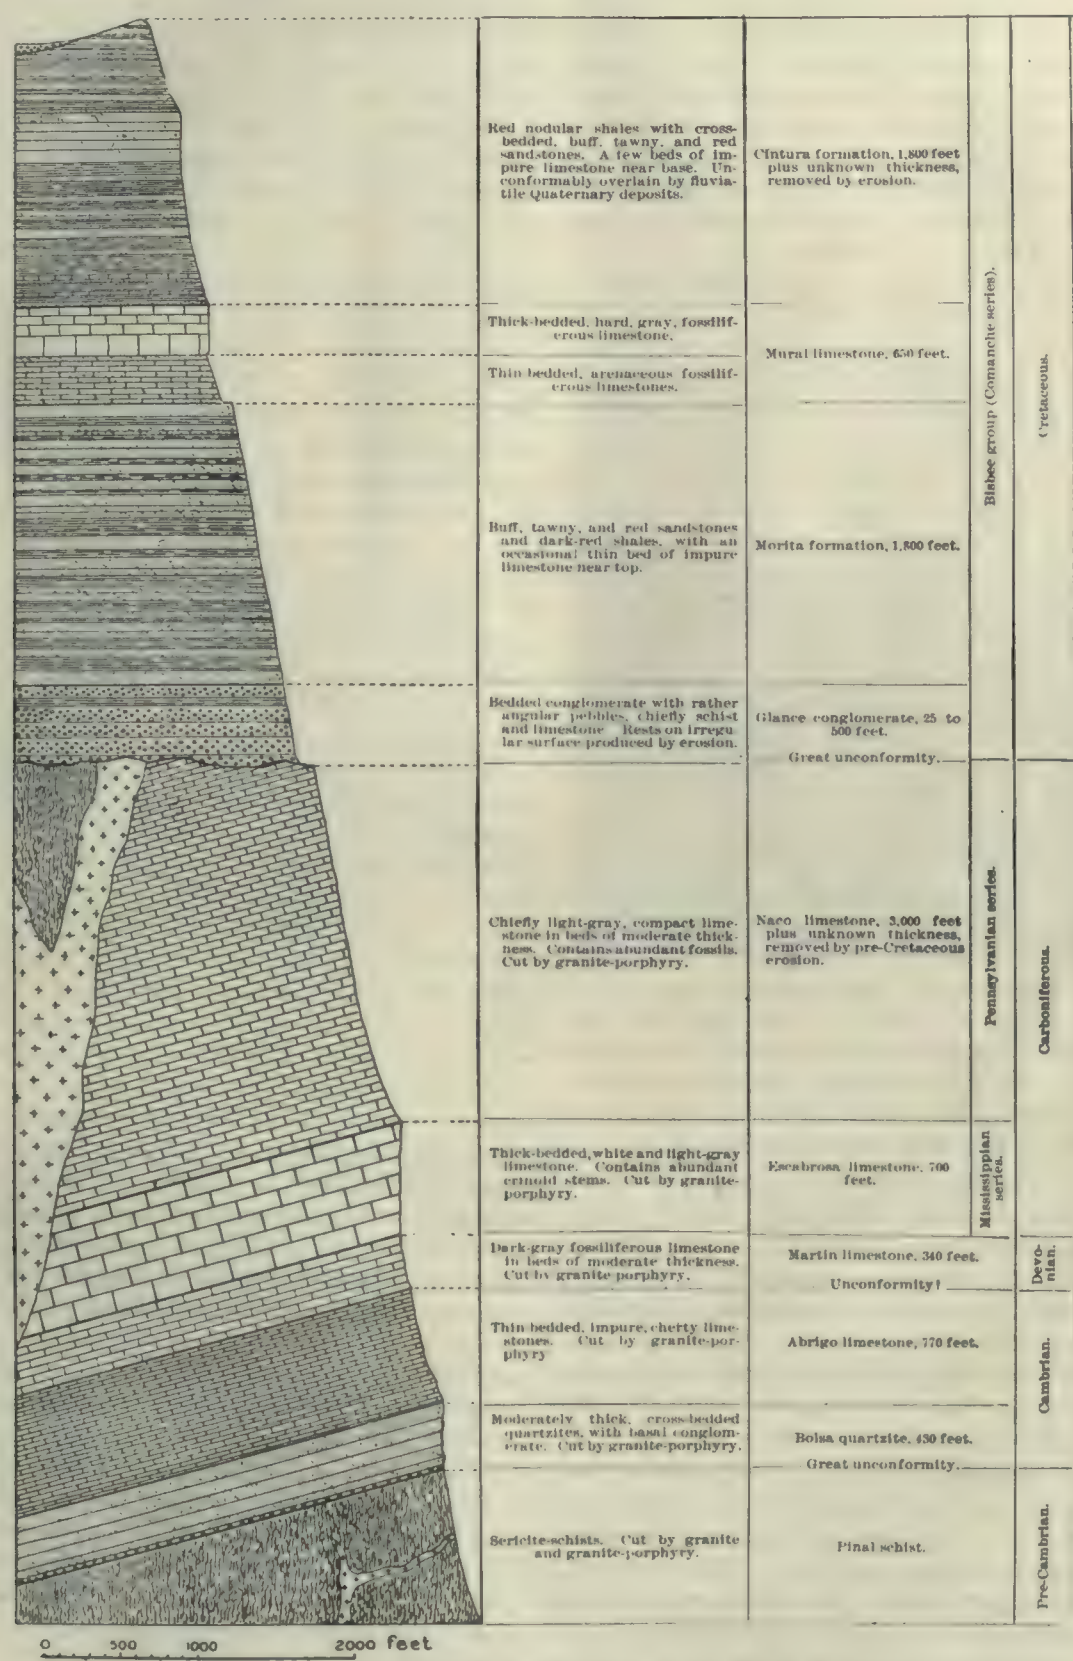

Fig. 1. Verde and Southeastern Arizona Copper Fields.

probably Tertiary. This brings the great Miami-Inspiration copper belt, which develops along the margin of the Schultze granite, in line with the other deposits of the Territory. My casual observations at Ray suggested that the granite and granite porphyry there belonged to this same late date, and J. E. Spurr informs me that his detailed study verifies this conclusion. Reasons will be given later for the writer's belief that an underlying granitic intrusion, this same Schultze granite, and not the diabase, is the origin of the deposits of the Old Dominion group, at Globe. This then brings these deposits in conformity with all other important mines or prospects of the Territory, as far as a close genetic relation to a post-Paleozoic acid intrusion is concerned. A few prospects of the Nacozari type are known in Arizona. The deposits develop in breccia zones in silicified lavas. The most promising of these are found in the Galiuro mountains, but their economic importance has not yet been determined. The Je-

some area and deposits are not included in this discussion.

Pre-Cambrian granites are not believed to develop copper deposits, and as it is important to distinguish these earlier intrusions from the later. Cretaceous 'kindly' formation for copper, and as the indications are quite different from those of the better known types of deposits, these indications will be discussed during the description of the Miami and Ray properties.

GENERALIZED COLUMNAR SECTION OF THE ROCKS OF THE BISBEE QUADRANGLE

Fig. 2.

teria for this purpose are given later. The greatest interest at present attaches to the deposits in the schist, and as there has existed a strong prejudice in the minds of prospectors against schist as a

Figures are notoriously uninteresting, but a few vital statistics are necessary if we would gain a definite mental picture of the importance of an industry. The production of Arizona can be taken to

represent that of the southern field under consideration, for although Clark's mines at Jerome and the adjoining properties are thought by some to be a separate field, and belong to a different class of deposits, formed at an earlier geological period, Cananea more than makes up for this loss. Geologically it belongs to the southern Arizona field. In round numbers Arizona has produced since 1880 two and a half billion pounds of copper, which, with the by-products, has yielded somewhere near \$400,000,000. Since 1906 Arizona's yearly product has exceeded a quarter of a billion pounds of copper, last year the production reaching 288,885,644 lb. out of a total for the United States of 952,395,477.

There seems no doubt that the new discoveries in disseminated deposits will keep the southern Arizona copper field at the head of the copper producing areas for many years, if not indefinitely. Indeed the question often discussed among those acquainted with the recent developments is: what are we to do with the flood of copper soon to come from Arizona's disseminated deposits? Is this class of deposit, with its low cost of production, going to drive the older mines out of business? As an answer to this question we may guess what will be the increase two years and again five years from now from these discoveries. Two years from now Miami will be producing about 25,000,000 lb. from the 2000-ton mill. Ray very possibly will reach 60,000,000 from the 5000-ton mill planned. This is an increase of about 30% on Arizona's present production.

A loss rather than a gain is to be expected from the old established mines, so that the present outlook suggests not much more than a doubling of Arizona's output. This means an increase from Arizona of $\frac{1}{2}$ of the present yearly world's production of copper. As nowhere else (with the possible exception of Africa and Chile) is there promise of developments approaching in value the recent finds in Arizona. It is not difficult to believe that advancing industry will consume without difficulty all the production from Arizona's new mines.

THE BISBEE COPPER FIELD.

It is hardly necessary to repeat in detail the history of Bisbee, the greatest of the Arizona copper deposits, and the third copper mine of the country, or more than to mention, in regard to its location, that it is in the southeastern part of the Territory, in Cochise county, and only a few miles distant from the International line. The Copper Queen was first located in 1873, was abandoned and re-located the next year; shortly afterward a third interest was wagered, won, and lost on a foot-race. The prospecting was done by miners from Tombstone, and from the Turquoise mining district, where Gleeson and Courtland now stand. Now Bisbee is returning the compliment and has built the town of Courtland, and is prospecting the Courtland and Gleeson mines. The statement has been made that the only outcrop of ore in the Bisbee district was an area 60 by 60 ft. This one lens was worked down 400 ft. on the incline. It contained 80,000 tons of ore, and produced 20,000,000 lb. of copper. During this period of muleback transportation and adobe furnaces the property passed into the control of L. Zeck-

endorf & Co., the enterprising Tucson merchants who have owned three of the great properties of the Territory, Copper Queen, at Bisbee, the Ray, and the Old Boot properties of Silverbell. Later Phelps, Dodge & Co. came into control. This fine lens of ore was found, however, to 'bottom' in barren limestone. This was the black time for Bisbee. Col. Herring, now long well known as the leading authority of the Territory regarding mining litigation, was trying to push down to orebodies, but a noted engineer told his backers that ore could not exist at depth in Bisbee. The Queen management gave positive orders to abandon further work, but Howell drove on along a stringer, doing the work against orders, and struck the second great lens of ore, and since then Bisbee has never been at a loss for 'pay rock.' In 1900 another man assisted greatly in the material advancement of Bisbee. Jim Hoatson would not believe that the orebodies stopped suddenly at the Queen's lines and purchased the Irish Mag from out of the Queen's fingers. The latter company wanted the claim, intending to attack the orebody from the adjoining Spray workings. The owner declared that no one could have the mine unless he would agree to start from the surface, and while the deal was held up on account of this ridiculous demand, the Calumet & Arizona intervened, and bought the claim for \$500,000, sank 800 ft. before running a drift, and struck ore. This single mining claim has produced between 100,000,000 and 120,000,000 lb. of copper, marketing for probably not less than \$15,000,000, and on this same claim good ore is still being opened, especially above where the ore was thought to exist on the 600-ft. level.

With the advent of new interests the apex law confronted the companies. All apexes are underground except that of the first discovered orebody, and it would be interesting to know how the courts would have decided the many possibilities. The question was settled in the only reasonable way, by an agreement drawn up by Col. Herring, the Copper Queen attorney, and since copied by other Arizona companies, by which each company renounced any extra-lateral right he might have in the other's property. Since this agreement Bisbee has had no law suits to determine the ownership of the orebodies.

Before F. L. Ransome investigated the Bisbee region, the geology was practically unknown, for James Douglas' excellent description was confined to the ore deposits. Mr. Ransome's work at Bisbee has been a credit to himself and to the Survey, and was of just the character that Government work should be. The general structural relations were worked out admirably. These have been the foundation for the more detailed geological work since carried out by the companies themselves. Fig. 2, taken from Ransome, shows the stratigraphic column. The earliest formation is the pre-Cambrian Pinal schist—then comes a thick Paleozoic series of quartzite and limestones, which has proved to be the locus of the ore mined up to date. Into these the Sacramento stock was intruded. It spreads out into the limestone as a network of dikes and sills. Later

than this intrusion and the formation of the ore, is the Bisbee group of the Cretaceous, important only because it is a covering formation. Here, as elsewhere in Arizona, the mineral-bearing formations were probably completely covered by later rocks. Fortunately the copper districts, after suffering the various 'porphyry' intrusions which gave birth to the copper deposits, generally underwent long-continued faulting movements, which produced elevations of the copper-bearing blocks. These uplifts have given to subsequent torrential erosion points of attack, and these coverings have been removed and deposited largely as detritus in the undrained or partly drained basins ('bolsons' and 'semi-bolsons') and especially on the long slopes leading down into these basins ('bajadas'). At the time the Bisbee survey was made, the very general genetic relationship of the copper deposits to the post-Paleozoic intrusions was not as well established as now, and Mr. Ransome did not consider it to be proved that the Bisbee copper was given off by the Sacramento intrusion and injected into the limestone by the su-

go deeper than expected. The relation of the ore-zone to the limestone syncline is the most important structural relation known to obtain in Bisbee. Of less importance is the relation of the orebodies to lines of faulting and fissuring. The relation of the Denn to the Dividend fault, and of the Shattuck to the Czar fault seems demonstrated. Certain large low-grade sulphide orebodies in the Calumet & Arizona properties are plainly developed along lines of fissuring. The Junction orebodies differ from all other deposits of the camp in that they are not in the ore-zone at all. They are vertical fissure-veins, 20 ft. thick. The ore-zone is calculated to be 600 ft. below these veins, or at the 1800-ft. level of the shaft.

The relation of the ore to the dikes is not shown convincingly in all parts of the camp. The relation

Fig. 3. Ore-Bearing Trough at Bisbee.

perheated waters. It seems now practically certain that this is so.

The three formations upon which interest centres for the mining geologist are the Pinal schist, the Paleozoic limestones, and the Sacramento intrusion. The latter came up along the great Dividend fault (see geological sketch) eating out from this fracture, and extending in ramifying dikes in all directions into the limestones. The large area through which these dikes appear suggests that the porphyry exposure is but the upper portion of an extensive underlying mass, with which these dikes connect. Many dikes have been found in the workings that do not extend to the surface, the upper 'feather edge' having in cases been found. The porphyry did not lift up the sedimentary beds and develop outward dips as is common elsewhere.

The Dividend fault bisects a southeast dipping syncline (see Fig. 3), and the intrusion, perhaps slightly turning up the truncated edge of this syncline, formed a structural trough or scoop, around the porphyry. The ore zone conforms in shape to this scoop, except that it does not dip at quite as strong an angle. The orebodies, however, are not strictly confined to the general ore-zone, they extend sometimes above the zone, as shown by the recent developments in the Irish Mag, and again probably

Sacramento Shaft, Copper Queen Mine.

is most evident in the Shattuck and Arizona, where the porphyry dikes are prospected for ore. Here also 'the lower lime' (Martin limestone?) seems to be the impervious floor above which the orebodies formed. The big orebody on the Del Norte 1300-ft. level is another good example of ore following a porphyry dike. The orebody here forms along the contact, and replaces the porphyry. It is apparent, however, that neither the relation of the ore to fissuring, nor the dikes, is constant enough to form a general guide to the prospecting. The method used is described later.

THE ORE DEPOSITS.

Interest centres in the ore lenses themselves rather than in their relations to geological formations, and structures. So various are their shapes, and so complicated are their alterations, that it is difficult to summarize them. The orebodies consist almost invariably of a kernel of rich ore, surrounded on all sides by a shell of oxidized lode-matter, incased in solid limestone. The upper capping of lode-matter is generally thickest, and looks like masses of lime boulders set in a matrix of mud or clay. The soft material is occasionally pure kaolin, but it generally carries limonite, sometimes mixed with the hydrated oxides of manganese.

This is a variety of the 'iron cap' but here the cap

does not generally come to the surface. In the vicinity of the Shattuck and Arizona, these iron areas show well on the surface, and are really outcropping lode-matter, so that the statement that Bisbee has no outcrops, is hardly correct. The shape of the orebodies is so irregular that it can only be stated that they have a tendency toward a tabular form. This irregularity can be appreciated from the fact that the Copper Queen company is still working 300 ft. from the surface alongside of stopes mined 20 years ago. It may be said that the stoped areas of the largest orebodies, measured in the plane of the ore-zone, may extend over several acres.

It is well known that Bisbee is a camp that has had remarkably high-grade orebodies, the high assay value of which has compensated for their great irregularity. Stopes averaging 16% are reported for the new orebody opened in the Shattuck and Arizona, and even 20% has been known, while 100 ft. represents the average maximum thickness.

The lode matter includes all the decomposition-products separating the ore from the solid lime. In one case Mr. Ransome describes the lode matter as pulverulent running silica. In some stopes small kernels and boulders of ore are found in the white kaolin. When driving through lode matter toward a large ore-pocket the first layer of ore reached is of higher grade than the average, and in the centre the kernel drops in value. In the sulphide bodies, the rich outer shell may be cuprite and native copper, then high-grade chalcocite, and then the grade drops somewhat. While driving through the ore if the grade begins to rise, the miner suspects that he is at the limit of the orebody.

The system of development to explore these irregular orebodies is: (1) to drive in almost any convenient direction until lode matter is struck; (2) this material is then thoroughly explored for ore; (3) when found, the ore is cross-cut and driven upon, and, (4) further development is done by actual stoping, the square set system allowing the following of the ore no matter how it may twist in and out through the lode matter.

UNDERGROUND WATER.

It has been generally supposed that the descending enriching waters of copper deposits are strongly acid, and stay so. Water analyses, made by Mr. Tobelman, chemist for the Calumet & Arizona company, show that in Bisbee the mine-waters are alkaline, except those coming out of open stopes, and, further, an acid mine-water is neutralized by agitation with limestone. It is the acid, thoroughly oxidized, open-stope water that has given rise to mistaken ideas, and I will present later data for believing that, at least for the limestone orebodies and the disseminated deposits in porphyry, the descending copper solutions contain an excess of CO_2 , that the copper descends as bicarbonate or silicate, precipitating, however, in the presence of pyrite as chalcocite, and that the excess of sulphuric acid has been neutralized. The copper waters from the stopes in the Bisbee mines are kept separate from the purer waters, and are elevated to the precipitating plants by separate pumps at the Czar shaft.

Bisbee has always been believed to be a 'lime-

stone' camp, that is, the ore is found only in the limestone. It is not certain, however, that a considerable portion of the completely decomposed lode-matter was not originally porphyry. The Sacramento stock itself is pyritized, but on account of its thorough silicification it has not been amenable to enrichment by descending waters, at least in the one place where it has been tested from the surface down. The Cochise Copper Co. sank its shaft through the schist into the porphyry. Silicification here also has sealed up the rock, the primary mineralization consisting of disseminations of pyrite and chalcopyrite, and networks of small veinlets of quartz with molybdenite, chalcopyrite, pyrite, galena, and sphalerite. It is reported by the miners that the Holbrook orebody, east of the Hospital, was in the Sacramento porphyry, but I did not have the opportunity of personally verifying this report. When viewed in the light of the developments in the porphyry and schist elsewhere in the Territory, it is significant of the great value of the limestone orebodies that the porphyry has received so little attention at the hands of the larger companies, and that the iron-stained schist adjacent to the porphyry intrusion has received practically none.

MINING METHODS.

To one who has visited Bisbee at intervals before, during, and after the great inflation and crash of the copper market, the changes in mining methods that the companies have made in response to the drop in value are interesting. Formerly at the Queen properties, stopes were carried up in large sections, timbers were cut to measure and fitted to a nicety underground. The practice was to take out only sufficient ground for one set at a time, and machine drills were not used in the stopes. Now small stoping drills are used wherever possible, small sections are taken for a stope, and run up quickly and filled in close, allowing a reduction of the size of the timbers from 12 by 12 in. to 8 by 8, and an increase in the height of the sets from 6 ft. to 7 ft. 2 in. Room for two sets is blasted out at one round, and the ore allowed to fall on the floor below, where it can be handled without delaying the work above. Only the main workings are kept open. No attempt has as yet been made to introduce caving methods, or filling methods without the use of timbers, it being maintained by the engineers in charge that the irregularity of the orebodies, and the high grade of the ore, which would make the loss of a few sets of ore a serious affair, forbids the use of any method except the square set. The installation of the electric haulage system, and hoisting by skips from a central shaft, has not only cut down tramming expenses, reducing the average hand-trams to 300 ft., but it has allowed centralization all along the line. For instance, sharpening is all done at one place, the steel being distributed by the haulage system. All this allows more careful supervision and consequent saving.

Separation of sand from slime in a spitzkasten is extremely imperfect unless the pulp-stream be introduced at the head of the apparatus at the proper angle, owing to interfering currents.

DREDGING AT BRECKENRIDGE, COLORADO.

By A. H. BRADFORD and ROY P. CURTIS.

MINING AND SCIENTIFIC PRESS Honorable-mention thesis; presented to the President and Faculty of the Colorado School of Mines, June 1909.

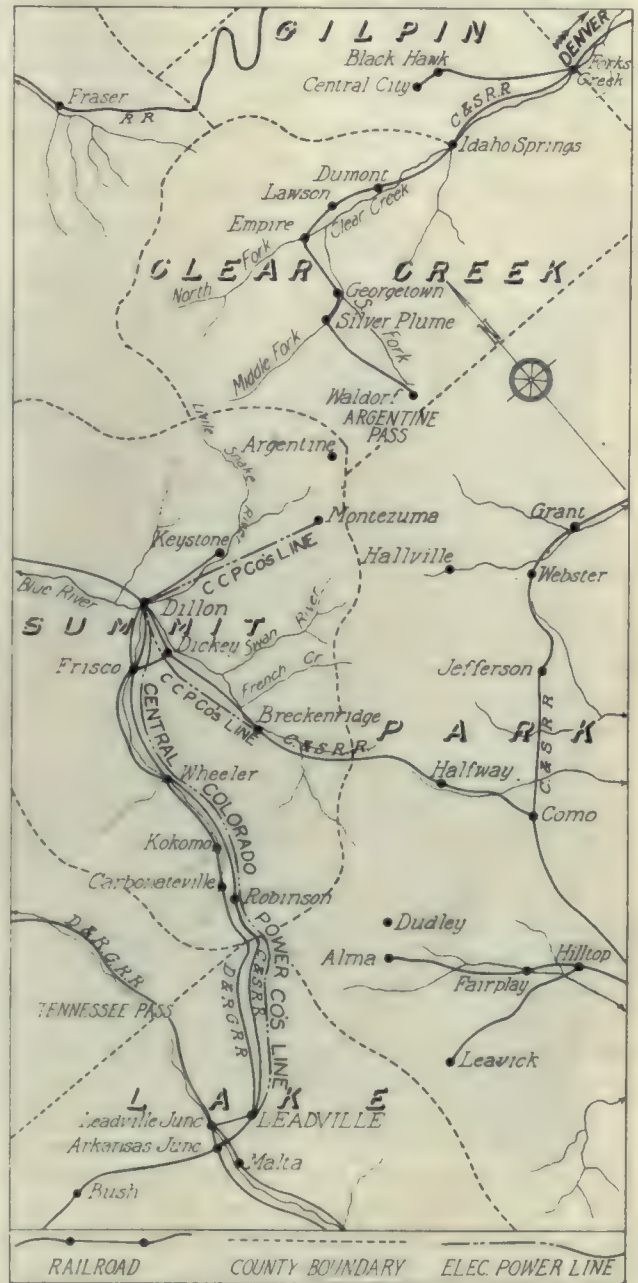

Breckenridge, the county seat of Summit county, Colorado, is situated 112 miles southwest of Denver, on the South Park branch of the Colorado & Southern railroad. The elevation is 9600 ft. above sea. The town has a population of 900. The Breckenridge district embraces the valleys of the Blue, Swan, and Snake rivers, together with the drainage-basins of their tributaries. These streams head on the western side of the main range of the Rocky Mountains, and consequently drain to the Pacific. Gold was discovered in the district during the year 1859, and a typical mining boom immediately ensued. In the early days, the district regulations restricted the length of placer locations to 100 ft., thus making extensive operations impossible. Later, when the 100-ft. titles had expired, and more liberal placer laws to secure a greater acreage had been passed, advanced methods of mining were introduced. In 1872, the booming system of mining was introduced, and later hydraulicking with giants became common. Since that time, both methods have been successfully practiced throughout the district. The first dredging for gold in this district was started in 1900, and since that time, all the advancement has been along this line.

There are few districts in the world more interesting in regard to their geological problems than Breckenridge. It may be described as a complex of sedimentary rocks, eruptive dikes, eruptive sheets, and batholiths. The sedimentaries extend from the Carboniferous to Upper Cretaceous. There are two classes of eruptives. One is a porphyritic diorite, which is found on the top of Mt. Baldy; this rock is usually considered barren, and a poor indication of mineral. The other is a quartz porphyry, and the largest mass is found on Mt. Lincoln; it is often called Mt. Lincoln porphyry. This rock is closely associated with the mineralization. Veins of lead, zinc, and silver occur intimately associated with the quartz porphyry, and placer-gold is often found concentrated upon or near one of these dikes.

One of the most remarkable features of this district is that some of the veins pass entirely through the Triassic limestones, the quartzite, and the overlying siliceous sediments, and contain ore in all horizons.

Extensive glaciation of the gold-bearing rocks about the head-waters of the Blue river and its tributaries has been responsible for the formation and accumulation of the vast amount of placer-gravels found in the Breckenridge district. Glacial gravels in many places cover the slopes of the hills, and the banks of the river and its tributaries. These deposits are known as 'bench placers', and extend all the way from Dillon to Breckenridge. These 'bench gravels' frequently cover the hillsides to a height of several hundred feet. They are comparatively fine as a rule, without clay or large boulders. The largest fragments of rock are generally angular pieces of porphyry and quartzite, retaining strong

evidence of their glacial origin. 'All the early workings have been in these bench deposits. In the present bed of the streams, however, and along their flood-plains are great deposits, varying in width from 100 yd. to a mile in places. These are known as 'river gravels'. They contain many water-worn rocks from 6 to 8 in. diam., with occasional boulders as large as 3 ft. diam. Porphyry is the predominant rock in the Blue and Swan river gravel. These gravels are firmly compacted and cemented by clay.

The Central Part of Colorado.

There is a clay-streak through all the deposits, which is probably derived from the disintegration of the porphyry matrix. This streak is usually richer than the gravel.

The depth of the gravel varies considerably in different places, as it appears to have been deposited on an uneven floor. Near Breckenridge at the Gold Pan workings, the depth is 76 ft. to bedrock; at Dillon, seven miles down the Blue river, it is 79 ft. to bedrock; between these points in the Blue and up the Swan, the depth is from 40 to 45. The Upper Blue, above Breckenridge, shows but little evidence of the influence of waters after their glacial depo-

sition. The deposits are very deep, the boulders large, while the gold is coarse and shows little action of water-wear. These large boulders were the prime cause of the failure of an extensive enterprise on the Gold Pan placer deposit. Below Breckenridge, on the Blue and on the tributary streams to the Blue, the water has modified the gravel to a greater extent. The bedrock of the dredging area consists principally of either porphyry or shale, or shale traversed by dikes of porphyry. The shale is often nearly horizontal. The best gold content is generally found on, or in the oxidized shattered porphyry, or on the top of the shale. The gold is found all the way from the 'grass-roots' to bedrock, and for a few inches or feet into the bedrock. The placer-gold of this district is probably derived more from gold particles disseminated through the igneous rocks, or portions of them, than directly from particular gold-bearing veins, as there are few such veins known in the district. The bulk of the ores worked in the existing mines are lead, silver, and zinc. There are notable exceptions, however, such as the celebrated crystallized gold deposits of Farncomb hill, occurring in fissures in shales adjacent to a mineralized dike of porphyry. The largest nugget ever found in Colorado, known as 'Tom's Baby', 7 in. long by 3 wide, and containing 156 oz. gold, was taken from the Farncomb hill placer. The other gold deposits are principally low-grade impregnations of volcanic rock, particularly of the Mt. Lincoln quartz porphyry. This variety of rock is common in the region and often, in a somewhat decomposed state, forms the bedrock of the productive placers. It is probable that the crushed and mineralized zones and fissures in this rock are responsible for the bulk of the gold found in the placers.

The gold value is generally between 10 and 50c. per cubic yard. While from \$2 to \$20 per yard have been reported from pay-streaks on bedrock, such quantities are rare. Gold pay-streaks occur in channels, not continuous, and the course and dimensions of these can be proved only by drilling or prospecting by shafts. The gold in the placers is coarse rather than fine, due perhaps to not having traveled far from its source. Large nuggets are uncommon, but small ones, half an inch to an inch long, and generally flattened, are not rare. They are rough, rather than water-worn, and sometimes show a 'wire' or crystalline structure. This is particularly true of those found in the placers immediately below the gold deposits of Farncomb hill. The gold fineness gives values per ounce between \$17 and \$18. Black sand occurs in considerable quantity, and is said to have a smelting value of \$75 per ton. The black sand is not all magnetite, and there is much gold coated by iron oxide, wherefore the failure to amalgamate it.

While, in former years, the 'bench gravels' have been extensively worked, it is the lower river gravels that are now the object of attack by modern placer-mining methods. Extensive operations in the past have been carried on by sluicing the 'bench gravels.' The operation of sluicing is simply a mechanical separation, accomplished by means of

flowing water. The gravel is thrown into a sluice through which a stream of water is running, and, because of the relatively high specific gravity of the gold, it settles rapidly through the current, and is caught behind riffles placed in the bottom of the sluice. Various systems of sluice-construction are to be found in the district. Perhaps the earliest work on the 'river gravels' was that done by the Pence Miller Co., in 1898, operating with hydraulic elevators near the mouth of French gulch, and on the Golden Crown placer near the junction of Indiana creek and the Blue river. The Oro Grande Co. also experimented with Evans elevators at about the same time, operating on the Blue river, near Dillon. The combination of a clam-shell digger with an elevator was then attempted by another company on the gravels a few miles below Breckenridge. Even up to the past three years, the Gold Pan Co., operating with a large and expensive equipment of Evans elevators, has done considerable work on the Blue, principally within the city limits of Breckenridge. The past operation on these 'river gravels' has in general proved a failure, due principally to the following reasons. (1.) The elevators were a mechanical failure because of their inability to handle the large boulders often found. Much extra work was required for their removal, thus adding to the operating expense. (2.) The clam-shell digger proved a failure in handling the stiff clay, gravel, and boulders of the district. The 'clam' never shut tight when closed, and thus allowed the fine gold to escape with the leakage water. (3.) In some cases, there was a lack of gold in the spots selected for experiment. In other cases, there was insufficient prospecting of the ground before building expensive apparatus which led to discouraging results and failure. (4.) In some instances, the ground selected for both elevating and dredging was too deep to bedrock for economical working. (5.) The early dredges built here were not adapted to the nature of the ground, being too light for the successful handling of the stiff cemented gravels and the boulders. (6.) Black sand has proved hard to contend with. Large quantities which were at times met, proved a great hindrance, especially on the gold-saving tables. Owing to its high specific gravity, it choked the riffles and prevented the catching of gold in them. The elevator, the clam-shell digger, and the light dredge have all proved failures. They are now succeeded by the latest and most powerful type of dredge, which has proved successful in the economical handling and efficient saving of the gold. Between 1897 and 1900, the North American Dredging Co. operated three dredges on the Swan river. In 1907, this company re-organized into what is now known as the Colorado Gold Dredging Co. The construction of two powerful Bucyrus dredges, at the junction of the Swan and the Blue rivers, marked a new era for this company.

The Reliance Gold Mining Co. operates a dredge in French gulch, about a mile and a half from Breckenridge. It is the oldest machine in the district, and has been in successful use for five years. The conditions met with in the immediate vicinity

are: (1.) Coarse gravel and small rock fragments. (2.) Large boulders. (3.) Streaks of sticky clay carrying the larger portion of the gold. These streaks must be disintegrated before the gold can be saved. (4.) A large percentage of the gold is coarse and rusty, and will not amalgamate. (5.) Large amounts of heavy black iron sand tend to clog the riffles. The dredge was originally driven by steam and is of the double-lift, open-connected type. During the last season, the motive power was changed to electricity, and the dredge remodeled. In a double-lift dredge, the material is elevated twice in its passage through the machine. The material is excavated by an endless bucket-chain, dumped into

The bucket-line consists of 42 buckets and 42 intermediate links, supported by a ladder which can be raised or lowered. The bucket-line is hung upon an upper and lower tumbler, placed at opposite ends of the ladder. The upper tumbler, which drives the bucket-line, is driven at a speed of 10 to 14 ft. per min. by a 200-hp. motor. The bucket-links are pinned to the blank links by forged-steel and manganese-steel pins. The buckets are of 9 cu. ft. capacity, and will dig about 2500 cu. yd. per day. The buckets discharge onto a grizzly with bars 18 in. apart. A stream of water is sprayed upon the material as it is dumped upon the grizzly to wash the oversize before it is discharged into the pond. The undersize

Hydraulic Mining, Breckenridge, Colorado.

a hopper, and screened. The undersize goes to a revolving trommel, and the trommel-undersize to a well in the hull whence it is elevated by means of a centrifugal pump to the sluices, 20 ft. above. Before remodeling the dredge, extraction was effected by means of a sluice, 120 ft. long by 4 wide, attached to the stern of the dredge and floating on independent pontoons. The chief objection to this arrangement was that there were no means for stacking the tailing, and the tailing-pile soon encroached upon the unworked ground, necessitating its re-handling. In remodeling, the dredge was changed by the addition of a stacker and the sluice flume was placed on board of the main hull, thus putting the gold-saving-device wholly on board the boat, and allowing the tailing to be carried far enough away so that there could be no danger of their impeding the operations of the dredge.

passes into a revolving trommel 14 ft. long, by 4 ft. inside diameter, made of $\frac{3}{4}$ -in. manganese-steel plates. The holes are 4 in. diam., spaced about 2 in. apart. At the lower end of the trommel and somewhat above its centre, is set a cylinder, 8 in. diam. by 18 long, attached to the end of a 6-in. water-pipe. This is set at right angles to the trommel, and is fitted with 24 nozzles, varying from $\frac{1}{2}$ to $1\frac{1}{4}$ in. diam., so directed that the water from them will spray the inside of the trommel and wash down the material. The material which passes through the openings in the trommel drops into a well-hole, 15 ft. long by $7\frac{1}{2}$ wide, from which it is taken up by a centrifugal pump and elevated 24 ft. to the discharge-chamber above. The pump is a common single-stage centrifugal, driven by a 100-hp. motor, and discharging into a 15-in. manganese-steel discharge pipe. All the water used in the sluices is also elevated by this

pump. The material is discharged with great force against a manganese-steel plate 30 by 30 in. and 4 in. thick, placed in the top of the discharge-chamber. This chamber is at the head of the sluice and empties into it. It is lined on the top, sides, and bottom with $\frac{7}{8}$ -in. steel-plates. The water carries the material over the riffles with great force. The riffles are set in a flume, which curves first to the left and then to the right, paralleling the centre line of the hull. The object of these curves is to obtain greater eddy-action in the current of water and to give the gold a better chance to settle into the riffles. The result is that over 80% of the saving is made in these two curves. This arrangement also gives a good distribution of weight on the hull. After making these curves, the flume is split into two arms set at an angle of 60° with each other. The main flume is 46 in. wide and 27 ft. long. From its end, the two arms, 26 in. wide, extend for 62 ft. These arms discharge 42 ft. back, and at the side, of the dredge, thus keeping the dredge free from the tailing-pile. The riffles are made of 1-in. wooden slats, $3\frac{3}{4}$ in. wide, set on edge, 3 in. apart, and shod with manganese steel bars, $2\frac{1}{4}$ in. wide by $1\frac{1}{4}$ in. thick. This gives a total depth of 5 in. with a $2\frac{1}{4}$ -in. space between the bars. These riffles are made in sections which are removed when clean-ups are made. The flume has a slope of 1 in. in 12 ft. of length. A 6-in. pipe entering the back of the discharge-chamber supplies water to be used in the clean-up, and also to keep the riffles from freezing when the dredge is shut down.

The oversize from the trommel is discharged upon the stacker-belt and conveyed up an incline of about 16° to the tailing-pile at the stern of the dredge. A 36-in. rubber belt is used, 220 ft. long and $\frac{3}{4}$ in. thick, making 1 rev. per min. The belt is supported by a stacker-ladder, which can be raised and lowered as desired. The belt is driven from the upper end by a 25-hp. motor. The belt conveyor is the source of the greatest trouble when cold weather sets in, as it freezes quickly and, once frozen, it is almost impossible to start it without damage. To overcome this difficulty, the company has placed a cover over the stacker-ladder. A canvas, 60 ft. long by 12 wide is stretched over iron hoops and attached to the ladder by eyelets in the edges. This cover, with the belt, forms a funnel through which warm air from the interior of the dredge-house naturally ascends; this, with the aid of a $1\frac{1}{2}$ -in. steam-pipe, run up and back under the ladder, keeps the stacker from freezing. By the addition of a heating-appliance for the inside of the dredge, and for the exposed parts of the digging-ladder, the necessity for closing during the past winter season was avoided, the Reliance dredge now being able to run all the year round. This innovation is due to Ben Stanley Revett, the manager. This heating is an important factor for consideration, since the months from November to February are severe. Heat is generated by a 30-hp. boiler. As one cord of wood lasts about two days, the cost of heating is not excessive.

Electric power is used. The current is delivered through an insulated cable from a portable transformer on the bank. Alternating current of 13,000

volts is stepped down to 440 at this transformer. Oil-switches are used. They are situated in the pilot house, which is above the upper tumbler. Every operation of the dredge is controlled from this point. The winches (side and rear lines), are started and stopped by a hand-controller, as is also the bucket-line. The pumps and stacker are controlled by starting rheostats. The various drives are controlled by induction motors of the following horse-powers: bucket line, 200; winches (ladder-hoist, spuds, side-lines, and stern-lines), 52; large pump, 100; stacker, 25; trommel, 75; making a total of 425 horse-power.

This dredge was designed by Edward Smith, and built to suit the conditions existing in French gulch. It is a combination of several well known types of dredges. The double-lift type was installed with the idea that the powerful flow of water would easily carry and wash the coarse gravel, whereas a lesser flow on the tables would cause a congestion; and that the sticky clay, which carries the rich gravel, would more readily be disintegrated by traveling a long distance and being churned through water under a high pressure, as well as being carried over the deep riffles in the long flume by swiftly flowing water, than by being merely forced through small holes in a trommel, and upon tables to be washed. The advantage assumed for the double-lift in this respect is that the clay is under the disintegrating influence of churning with water for over 100 ft.; with the other type, if the clay is not disintegrated in passing through the screen it is carried over and passed out with the waste and the gold is lost. Pieces of gold which would not pass through a hole of $1\frac{1}{2}$ -in. diam. have been taken out of the Reliance dredge. Consequently, these nuggets would have been lost in the usual sized screen. Again, the long travel would tend to scour the rusty gold and make it amenable to amalgamation. The depth of the riffles on the sluice and the velocity with which the water flows, does away to a great extent with the clogging by black sand.

The Colorado Gold Dredging Co. has two Bucyrus dredges at Valldero, five miles down the Blue river from Breckenridge. One is working down-stream in the Blue river, the other up-stream in the Swan. These dredges have operated but one season. The dredge working up the Swan river is designed to dig 38 ft. below the surface of the water, and the other 48. The latter dredge has worked down the Swan and is now at the junction of the Swan and Blue rivers, and will continue down the Blue. Both dredges are of the open-connected, single-lift bucket-elevator type. The material is excavated and lifted but once, and progresses by gravity from the time it leaves the bucket until it is discharged back into the pit as waste. There are 42 buckets and 42 links in the chain. Each bucket-capacity is $9\frac{1}{2}$ cu. ft., the dredge excavating 3000 yd. per day of 24 hours. The bucket-lips are of manganese-steel. The bucket-line is driven by an upper tumbler, which is actuated by a 200-hp. motor. Except for the length of digging ladders and spuds, the machinery and construction is the same for both dredges.

The buckets carry the material up over the upper

tumbler, and dump it upon a grizzly which ejects into the pond all stones larger than 18 in. diam., by a stone-chute passing over the side of the dredge. The gravel passes through the grizzly into a hopper, and is discharged aft into an inclined revolving trommel, 38 ft. long by 6 diam. This trommel is made of steel plates, 1/2 in. thick. The holes are 3/8

dredge, sloping aft, and extending out over the stern. The material which passes through the 13 1/2 in. square holes at the lower end of the trommel is picked up by the stacker, carried aft, and dropped at the end of the conveyor, thus filling up the pond behind the dredge as it moves forward. The belt-conveyor is supported by a steel latticed frame about

in. diam. at the upper end, 1/2 in. diam. through the middle part, while near the lower end, is a short section provided with 1 1/4-in. holes in order that nuggets larger than 1/2 in. diam. may not be lost by passing out through the double row of apertures 13 1/2 in. square at the lower end. The material after passing through the smaller holes is washed over

100 ft. long, suspended from the stern gantry; this is commonly spoken of as the stacker. The over-size from the 13 1/2-in. holes is discharged at the lower end of the trommel into a chute, and thence over the side of the dredge into the pond. There are four cast-hoops set inside of the screen at intervals of 6 ft. These form obstructions to the material, as they extend inward 3 in. from the trommel-plates, and are so placed in order to aid in disintegration of whatever clay may be in the gravel. Water for washing the gravel over the gold-saving tables is supplied by two centrifugal pumps, a 5-in. and a 12-in. The pumps are driven by a 75-hp. motor placed between them. A large spray-pipe passes through the centre of the trommel. This breaks up any lumps of clay and gravel and washes the material through the perforations in the screen. Pipes across the upper ends of the tables regulate the flow of water over them. Streams of water are thrown upon the bucket

Bucyrus Dredges Beginning Operation, Swan River.

the gold-saving tables. These tables extend across the dredge on both sides of the trommel. The tables are provided with riffles made of strips of wood about 1 in. square, spaced 2 1/4 in. centre to centre. These strips are protected on their upper edges with 1 1/4 by 1/8-in. steel bars. The tables slope 1 1/2 in. per foot. They discharge into sluices at the side of the

while dumping. This washes off any gold clinging to the buckets, which would otherwise be carried beyond the hopper and lost. An 8-in. double-drum winch is placed forward on the starboard side of the dredge. This is used for swinging the dredge and hoisting the heavy spuds. The digging-ladder which carries the buckets is raised and lowered by a wire-

rope tackle leading to a single-drum winch on the port side. This winch is driven by a friction clutch by the 200-hp. motor which drives the bucket-line. On coming upon ground containing a large proportion of fine material, a sand-pump driven by a 75-hp. motor on the stern is started. This sand and gravel is allowed to pass into a sand-box at the end of the tables instead of being discharged near the stern where it would flow forward under the hull and ground the dredge. The sand-pump takes the fine material from the sand-box and carries it through a pipe out along the stacker, and discharges it at a distance from the dredge.

The electrical power for operating the motors is supplied by the Central Colorado Power Co. The total horse-power on each dredge is about 430. The electric power is transformed from 13,000 volts down to 440 volts before leading on board of the boat. The motors operate on 440 volts, and the lighting system at 110. The motors used are: main drive or digging-motor, 200 hp.; sand-pump motor, 75; water-pump motor, 75; stacker, winch, and trommel-drive motor, 25; stacker-motor, 20; winch-motor, 20; deck-pump motor, 15.

The hull is 115 ft. long, 40 ft. 6 in. wide, and 9 ft. deep. The sides are curved inward at the forward end, making the bow 26 ft. wide. An open well, 6 ft. 6 in. wide for the digging-ladder, extends aft from the bow about half the length of the hull. Both the digging and walking-spuds of these dredges are made of structural steel, with extra-heavy cast-iron points. The walking spud weighs 24,000 lb. and the digging spud, 45,000.

About every two weeks, depending on the richness of the ground, the dredge is shut down for a few hours to clean up the gold-saving tables. The riffles are removed and the coarse gravel washed over the stops at the centre and lower ends of the tables, leaving the amalgam and black sand behind. This is gathered up and fed into a 'long tom' rocker. The amalgam and quicksilver are caught in the riffles of the 'long tom'. The amalgam is then drained and retorted.

The Colorado Gold Dredging Co. dredged during the last season at a cost of 8c. per cu. yd., everything included; and as nearly as can be ascertained, the average saving was from 12 to 14c. per yard. The gold-saving under the best conditions is estimated to reach 80%. In California, it has been as high as 85. For purpose of comparison, costs in other districts are here given. In the California dredging fields the average costs are said to run about 5½c. per cubic yard. Under the most favorable conditions, costs as low as 3c. per yard have been obtained. Gold-dredging in Alaska is done under more unfavorable conditions. Much of the ground is frozen and must be thawed. Where the ground is unfrozen, dredging can be done at a rate of from 12 to 40c. per cubic yard.

Nitrate business in Chile is badly disturbed over the dissolution of the nitrate combine that ended March 31, 1909. The price of nitrate has declined materially, and several works have shut down. A strong effort is being made to agree upon some

working basis to control the market and keep up the price. The Chilean government is taking a hand in the matter, since it is deeply interested, as there is an export tax of 56c. United States gold per Spanish quintal of 101.42 lb. On January 31, 1909, there were 145 separate nitrate works in Chile, and it is a difficult matter to get all the interests together. There are several strong companies that own several plants each, and it is among these that the most opposition to combining is found. The following table covers the average cost of nitrate per quintal in United States gold under the conditions given during the month of May for the years 1905, 1906, 1907, and 1908:

| Selling condition. | 1905. | 1906. | 1907. | 1908. |
|--|--------|--------|--------|--------|
| On board steamer in Europe..... | \$2.46 | \$2.38 | \$2.21 | \$2.12 |
| On board steamer in Chile with freight paid | 2.26 | 2.34 | 2.46 | 2.19 |
| Alongside steamer in Chilean port. | 1.84 | 1.96 | 2.13 | 1.79 |

During May, 1909, the price of nitrate was quoted as low as \$1.60 United States gold per quintal delivered alongside steamer in Chilean ports.

Placer-claims to any number may be located by a single individual under the United States mining laws. Where an individual makes the location, a single claim cannot exceed 20 acres, but an individual may locate as many of these claims not exceeding 20 acres, as he sees fit, provided each location complies with all the requirements of the mining laws. Of course local laws and regulations may place a limit on the number of claims that an individual may locate, and the existence of these must be ascertained for each particular locality. An association of eight individuals may include in one placer location 160 acres, and locations may be made by associations of individuals less than eight in number provided the location in each instance does not exceed 20 acres multiplied by the number of individuals included in the association. Unless the State laws prescribe the performance of preliminary or location work, the locator of the mining claim does not have to perform any work until the end of the year following the year in which he locates; by that time he must have done \$100 worth of work for each claim. The claim may rest for the remainder of each year provided this annual requirement of \$100 worth of work is done during the year. If there is a State law requiring a certain amount of work to be done at the time of the location of a mining claim, this, of course, must be complied with and the work to the required amount completed within a reasonable time, when the claim may be allowed to rest and no work need be performed, until the end of the following year. Assuming that 'A' locates a placer claim during July, 1908, and performs all the work required by the State laws, he does not have to do any further work until the end of the following year, and unless he abandons his claim meanwhile, it is not open to re-location until January 1, 1910. A location made by 'B' on January 1, 1909, would not be valid, and if 'A' failed to perform his assessment work during 1909, 'C' could initiate a valid location on January 1, 1910, which would prevail as against both 'A' and 'B.'

TREATMENT OF SULPHIDE ORES IN VICTORIA.

By S. RADCLIFF and J. DREVERMANN.

*For many years it has been the practice at the Bairnsdale School of Mines to treat any parcels of auriferous concentrate sent in by roasting them in a hand-worked reverberatory, and then chlorinating or cyaniding the product. According to Donald Clark, who has done a large amount of work on these ores, the results obtained were fairly satisfactory, extractions of over 90% being claimed. With some modifications, the method has been very generally adopted, not only in Gippsland but throughout Victoria. It is, however, difficult to get exact information as to the extractions actually obtained, and, unfortunately, no records of working results have been kept at the Bairnsdale School of Mines. Having treated several lots of ore by this method during 1907 and 1908 with unsatisfactory results, we thought it desirable to make a detailed investigation on some particular ore, both in the laboratory and on a working scale. The ore selected was a parcel of low-grade concentrate from Stirling, a small mining field about 40 miles east of Bairnsdale. This ore was chosen chiefly on account of the heavy and inexplicable volatilization-loss which took place, even on roasting with the greatest care; the loss amounting to between 10 and 15%. In the experiments here related, three main objects were kept in view: (1) To determine with what mineral or minerals the gold and silver were associated. (2) To gain information as to the cause of the volatilization loss. (3) To see if a satisfactory extraction could be made without roasting.

In endeavoring to answer the question why a given ore does or does not permit of a high extraction of its gold and silver content, a simple analysis of the ore will give small information. The essential point is, not what is the percentage of a given element, but, rather, with what element or elements are the precious metals intimately associated. For instance, the amount of tellurium in an ore may be much under 1% and yet its influence on the treatment is all important. Considering the amount of time and money expended, with moderate success, on some of the Victorian ore deposits, it is surprising how meagre the information as to the actual distribution of the gold and silver is. The case of the Bethanga field may be cited, where many thousand pounds sterling have been expended without arriving at a satisfactory treatment. The ores are exceedingly complex, containing, according to Donald Clark, pyrite, pyrrhotite, arsenopyrite, chalcopyrite, blende, and galena. We have, however, been able to find only two references in the literature bearing on this point, namely, one by H. C. Jenkins, to the effect that all the minerals carry some gold; and another by Clark, who states that "It is probable that the gold is excessively fine, or that it exists in a combined state, probably as telluride." No experimental evidence is given in either case.

In the experiments which we made, the procedure

was, first, the ore was passed through a series of sieves, the separate fractions analyzed and assayed, with the results shown in Table I.:

TABLE I.

| | | Percentage of Assay Insol- | | ore passing. value. ule. | | Fe. | S. | As. | Total. |
|------------------|----------|----------------------------|------|--------------------------|------|------|-------|-----|--------|
| Size of sieve. | through. | Au, oz. | % | % | % | % | % | % | % |
| Original ore.... | ... | 2.6 | 44.9 | 23.1 | 16.0 | 9.0 | 92.9 | | |
| On 30..... | 3.7 | ... | ... | ... | ... | ... | ... | | |
| On 60..... | 57.0 | 1.9 | 53.3 | 21.2 | 16.2 | 8.0 | 97.7 | | |
| On 80..... | 5.7 | 1.15 | ... | ... | ... | ... | ... | | |
| On 120..... | 20.4 | 1.6 | ... | ... | ... | ... | ... | | |
| On 150..... | 5.7 | 1.7 | 42.8 | 26.8 | 19.6 | 9.4 | 98.6 | | |
| Through 150... | 7.4 | 4.8 | 34.1 | 29.9 | 23.8 | 12.3 | 100.1 | | |

The samples marked original ore, on 60 and on 150 all contain lime. As might be expected, the brittle minerals have concentrated in the finest fraction, with a corresponding increase in assay value. This increase, however, is greater than would result from the simple concentration of the sulphides and arsenides. As will be seen presently, this increase is partly due to the presence of finely divided free gold and amalgam.

The finest fraction was then taken and passed through a Richards tubular classifier. In this apparatus the ore particles are subjected to the action of an ascending column of water, the velocity of which can be regulated with precision. Minerals differing only slightly from each other in specific gravity can be readily separated from one another by this means. The material was subdivided into a number of fractions by being repeatedly passed through the classifier; the velocity of the water-column being increased each time. Two of these fractions, one representing the lightest of the sulphur and arsenic minerals, and the other the densest (excluding a small, very dense fraction containing metallic iron, free gold, and amalgam), were taken. These were assayed and analyzed. The results are given in Table II.:

TABLE II.

| | | Assay In- | value. soluble. | | Fe. | S. | As. | Total. |
|----------------------|---|-----------|-----------------|------|------|------|-----|--------|
| Au, oz. | % | % | % | % | % | % | % | % |
| Light minerals | 7 | 29.6 | 34.2 | 26.0 | 9.0 | 98.8 | | |
| Heavy minerals | 5 | 5.7 | 35.9 | 33.3 | 25.0 | 99.9 | | |

Several points of interest may be noted from the results set out in these tables. In the first place there is the marked difference in the assays of the two fractions on, and through, the 150-sieve. Secondly, there does not appear to be any direct relation between the amount of arsenic in a fraction and its assay value. In fact, there appears to be no relation of this kind with regard to any of the principal constituents. The results shown in Table II. are remarkable; the light fraction assaying decidedly higher than the dense one, although the latter contains nearly three times as much arsenic as the former. This result was carefully checked, and it cannot well be due to the presence of free gold. The ore contains, in addition to the constituents shown, minute amounts of lead and copper, and also small amounts of what appears to be tin. It may be noted that the fraction richest in gold carried most of the latter. Further investigations are being made in connection with this sulphide, as its identity is not

*Abstract from 'Proceedings' Australasian Institute of Mining Engineers, May 1909.

quite clear. We have also tested the ore repeatedly for tellurium, always with negative results. The entire absence of zinc is remarkable, as it is commonly a constituent of these ores.

The analytical data throw light on the question of volatilization, or on the treatment-results. It is not at all evident why bromo-cyanide should give such a high extraction as compared with simple cyanide.

While the treatment tests were in progress, the following methods were applied: (1) Roasting and chlorinating. (2) Roasting and cyaniding. (3) Cyaniding the raw ore. (4) Bromo-cyaniding the raw ore.

(1) Gave an extraction of about 15%, calculated on the roasted ore. (2) Gave much lower results. (3) An extraction of 25%. (4) Several tests gave an extraction of 85%, with a moderate consumption of cyanide. The solutions were made up according to the directions given by E. W. Nardin.*

In view of these results, the authors decided to treat five tons by bromo-cyanide. The results tallied fairly close with those in the laboratory, giving an assay of ore before treatment of 2.6 oz., and after treatment of 0.45 oz., the extraction being 81%. A sample of the tailing was dried and sieved. The fractions on the 60 and through the 150-sieve were assayed. The fine fraction assayed 2 dwt. more than the coarse one. Laboratory tests were also made by grinding the tailing to pass through the 150-sieve, and treating further. The extraction was brought up to 85%. In cleaning up the zinc slime all the acid-solutions were examined. A considerable amount of sulphide giving the reactions for tin was collected. This tin must, presumably, exist in the ore as stannite or as some similar mineral, because cassiterite would hardly be soluble in dilute bromo-cyanide.

The above method of treatment seems never to have been seriously tried in Gippsland, and it certainly offers decided advantages over existing methods.

At the Cassilis Gold Mining Co.'s mill, the principal mine in the district, the gold recovered per ton crushed averages a little over 18 dwt., and over 40% of the yield results from roasting and chlorination. Roasting costs 9.91s. per ton, and chlorinating 10.80s., or a total cost of 20.72s. per ton of concentrates. The extraction is stated to be 84.6%. The ore certainly differs considerably in composition from the Stirling ore, and the volatilization-loss may be lower, but some loss certainly takes place. On chlorinating the ore from a neighboring mine, the concentrate being roasted in an Edwards furnace, it was found that considerable loss invariably took place, and this could not be ascribed to simple dusting. Apart from this, however, if a fair extraction can be got, it should be possible to bromo-cyanide the concentrate at considerably less than 20s. per ton.

Gas-engines utilizing producer-gas can develop 1 hp. hour with $1\frac{1}{4}$ lb. coal, producing an efficiency of 22 to 25%. No such efficiency is obtainable when developing and using steam-power.

SCALING AND SWEATING OF COPPER-BATTERY PLATES.

By SYDNEY F. GODDARD.

*During the month of February, 1908, at the Evaneon mill, north Italy, two outside copper plates, each 12 by 5 in., were scaled and sweated to remove the hard gold amalgam that had gradually accumulated during the previous 50 months' running of a 10-stamp mill, in which period 33,000 tons of quartz ore, averaging 11.74 dwt. gold, and 1.5 dwt. silver per ton, were crushed, of which an average of 10.94 dwt. gold and 1.40 dwt. silver were amalgamated and recovered as bullion, having a gross value of £76,889. The plates were originally silver-plated with 1 oz. of silver per square foot. Before removal, the plates were cleaned up hard, with the clean sharp edges of hardwood scrapers and rubbers until they presented a gray dry appearance, producing in this way 17 oz. of stiff pasty amalgam, which is not included in the return from scaling, as it was in the nature of a daily clean-up, only done in a somewhat more severe manner.

After removal, the plates were placed upon low trestles and sharply tapped with a wooden mallet on the under side, this being sufficient to crack and loosen the skin of hard amalgam, making it come away in thin angular scales. In this way 675.164 oz. of clean dry amalgam was obtained. The plates were then slightly heated over a fire and scraped with steel scrapers, and in this way produced a further 166.119 oz. of amalgam, making a total of 841.283 oz. of dry amalgam, which yielded a 'retort' weighing 331.250 oz. (39.3%) melted to 327.93 oz. bullion, leaving the following fineness, Au 834, Ag 134 (as against the 50 months' average of 875 Au, 115 Ag). The value of this bullion was 273.49 oz. fine gold, worth £1162 6s. 10d. and 43.28 oz. silver, worth £5 8s. 2d., or a total of £1167 15s.

A little amalgam still remained on the plates that could not be easily removed by scraping, together with the small amount it was presumed the plates had absorbed, so they were shipped to London for sale, with the following result:

Weight, before melting, 5 cwt. 2 qr. 7 lb. 0 oz.; weight, after melting, 5 cwt. 2 qr. 4 lb. 6 oz. The assays gave: 55.53 oz. gold per ton, £227 13s. 6d.; 5.30 oz. silver, 11s. 6d.; 97.50% copper £39, making a total value of £267 5s. The above assay indicates that the two plates as shipped yielded 15.372 oz. fine gold, and 1.467 oz. fine silver. The total gross value obtained from the two plates was £1241 15s. Samples of the plates were cut from the lower halves, and tested to determine if they had absorbed any gold. No gold was found in the samples taken. Samples from the upper halves, where the amalgam skin was thickest ($\frac{3}{32}$ in.), only showed traces, and went to demonstrate that only an exceedingly small percentage of gold was actually absorbed by the copper.

Fifteen per cent of the energy of coal is realized as useful mechanical work with the latest type of apparatus, including water-tube boilers, super-heaters, and steam turbines.

*Abstract from Bull. Inst. Min. & Met.

Free Settlement Method of Separating Slime.

Written for the MINING AND SCIENTIFIC PRESS
By HORACE G. NICHOLS.

During the past year considerable work has been done with a view to applying the method of slime-settlement which I described in the MINING AND SCIENTIFIC PRESS, May 22, 1908, to the treatment of slimed ores by cyanide. The many disadvantages attendant upon vacuum filtration methods have been from time to time noted by engineers adopting these processes and the possibilities for a more

that vacuum filtering is not the last development we shall see in slime-treatment," and the reason for this lack of satisfaction is no doubt to be found in the mechanical difficulties experienced in practice in efficiently carrying into effect the attractive process which vacuum filtering undoubtedly is. The overcoming of these difficulties cannot be accomplished without an amount of care and expense which the simplicity of the separation of solids from liquids would not seem to warrant.

We have the construction and repair of filters carefully attended to in order to provide uniformity of cake as an essential to proper washing, the handling of these filters, the return backward and forward of the pulp, the careful regulation of the vacuum during the time that the cake is exposed to the air, the losses due to osmotic force and the enrichment of the wash solutions, the constant agitation of the pulp in the filter-tanks, the necessity for a fineness of grinding which may not be economically advisable from the point of view of extraction, the intermittent nature of the operation, limitations of washing or cost of installation and operation as disadvantages in one or other of the many processes at present in vogue.

If all these disadvantages can be overcome at once by taking advantage of a principle of free settlement in which the solid particles are assisted to settle out themselves in a continuous flow, and this without dependence upon any variation or regulation in the working of machinery, a great field would be opened up. That this can be done is now proved, and the machinery required is so inexpensive

as to place the process in a class by itself.

The plant has been working continuously on slimed ore, of which 61% passed 200 mesh, 31 passed 100, and 7 remained on 100 mesh, removing the solids in compact form, carrying 27% moisture, and after thoroughly disintegrating and washing the same, with 3 tons of wash water per ton of

Nichols Slime Separator at Ymir, British Columbia.

simple method, which would eliminate these disadvantages, have justified concentration of attention upon the method indicated.

A plant has been constructed capable of handling 100 tons of fine slime per day and is now in operation at the Queen mine near Salmo, British Columbia. This plant embodies

Ideal Section, Showing Arrangement of Nichols Slime-Separator.

several improvements upon the idea originally suggested. A reference to the accompanying sketch of one unit will demonstrate the extreme simplicity of the plan. As previously described the method is based upon the principle of assisting settlement by removing solids in a settling vessel as they settle, and the truth and feasibility of application may now be said to be amply proved. It may be well to enumerate some of the considerations which led up to the desirability of an improvement upon present methods of slime-treatment. While in no way attempting to detract from the usefulness and ingenuity of the several methods of caking slime, it may be stated broadly that, as R. Gilman Brown has said, it has been "in the minds of many of us

solids, supplied through a spray which washes the load off the belt in the little continuous-flow, air-lift agitator, at the head of the machine, delivering a continuous flow of pulp for separation in a second unit in a similar way. The solution is withdrawn from the top of the pulp where it is thinnest, in fact, the settling action so assisted by the continuous removal from the bottom is so positive as to allow, in a great many instances, simply passing the solution from the top of the tank, which is only just cloudy, through sand filters.

In the plant referred to and in operation, simple filters are used, the pores of which are intermittently cleaned by a back-pressure of air supplied through a double-ended

piston-valve worked by an auxiliary valve, which in its turn is operated by a simple cam-wheel device. One of the principal objections which was originally suggested to the continuous operation of this particular form of machine, in which the belt returns in the tank itself, was that slime would accumulate in course of time in the bottom of the tank. This objection is overcome by the use of two 2-in. pipes shown at the rear end of the tank, which pass down into the tank to within 3 in. of the bottom and act as air-lift columns, a very small amount of air being introduced from below through the $\frac{1}{2}$ -in. pipes also shown. It is to be noted that the top of these pipes is below the level of the pulp. The merest bubble of air is enough to maintain sufficient circulation to absolutely overcome any accumulation of slime, the tank being kept perfectly clear.

Data in connection with this installation, which is standard size, are as follows: belt 2 ft. wide traveling 6 ft. per minute over 14-in. rollers, 25 ft. between centres; depth of tank at deepest part to upper side of belt, 6 ft. 6 in.; width of tank at deepest part, 5 ft. 6 in.; the amount of power required is very small, as may be judged.

It will be seen that the operation is absolutely continuous. There is no variation of vacuum necessary. The perfection of washing is entirely independent of any previous condition or adjustment; it is entirely immaterial whether the pulp treated be of a uniform degree of fineness; sand, slime, or sand and slime, can be handled by this method, and therefore re-grinding need only be carried to an extent demanded for securing economic extraction; there is no mixing of strong and weak solution; no special attention is required; and the necessity for maintaining the solids in suspension during the process of separation, which is an essential feature of vacuum-filtering, is entirely done away with, and in this connection the density of the pulp fed to the machine can be within wide limits. It is this necessity for maintaining suspension that in many cases calls for excessive re-grinding.

Catalogues Received.

The STERNE BROS. Co., San Diego, California, has lately issued a handsome catalogue in which the West Coast gas and gasoline engine is fully described and illustrated.

THE SWEETLAND FILTER PRESS Co., Los Angeles, has just issued its Bulletin D, describing the slime filter recently perfected, and giving results of tests on standard-sized machines.

The INGERSOLL-RAND Co., New York, has issued under date of July its Bulletin No. 4009, giving full details concerning the line of 'Electric-Air' rock-drills now made by that company.

THE J. GEO. LEYNER ENGINEERING WORKS Co., Littleton, Colorado, describes in its Bulletin No. 1007 and 1008 Leyner hand drills and Leyner drill sharpeners, respectively. They will be sent to any one interested.

The WESTERN ELECTRIC Co., New York and Chicago, is distributing a bulletin illustrating the Sunbeam tungsten miniature lamp for use on voltages between $1\frac{1}{2}$ and 20. These lamps vary in efficiency from 0.9 watts per candle-power to 1.33 watts per candle-power, and are desirable for use in automobiles, flash-lights, signs, dental, optical, and surgical instruments. A copy of this Bulletin No. 8-A may be obtained from the Western Electric Co.'s nearest house.

Commercial Paragraphs.

The ALLIS-CHALMERS Co., Milwaukee, has entered the field as manufacturer of machinery for sand-line brick and employed as commercial engineer, Franklin Henshaw.

MORGAN & Co. announces that it has succeeded to the business of the Brausch-Morgan Co., and will conduct a laboratory for ore testing, refining, and assaying at 227 South Main St., Los Angeles.

CHALMERS & WILLIAMS, Chicago, advise that among other contracts recently received is one for a 10-stamp cyanide plant with Burt filter and power and electric plant for the Barranca Mines (Mexico), Ltd., Torres, Sonora, Mexico; also a 15-stamp mill with power for the Mexico Consolidated M. & S. Co., Tepehuanes, Durango, Mexico.

Standardizing Electrical Mine-Equipment.

The American Mining Congress seeks to reform methods of installing electrical machinery in mines. At the Pittsburgh session, in December last year, a resolution was adopted authorizing the appointment of a committee of seven persons to report back for the consideration of means for bringing about the standardization of electrical equipment in mining and recommendations looking to uniformity in electrical practice in general. The resolution, which was introduced by David B. Rushmore, of the General Electric Co., was as follows: "Recommended, that a standing committee be appointed by the president of the American Mining Congress, to standardize as far as possible and make recommendations concerning electrical practice in mining work, said committee to consist of seven members as follows: one electrical engineer, two representatives of the manufacturers of electrical equipment, two representatives of the labor organizations, and two mine operators."

The following members were appointed by the Mining Congress to serve on this committee: Edward B. Rosa, of the Bureau of Standards, Washington, D. C., chairman; David B. Rushmore, of the General Electric Co.; W. A. Thomas, of the Westinghouse company; J. R. Bent, of the Oglesby Coal Co., Oglesby, Illinois; George R. Wood, of the Pittsburgh Coal Co., Pittsburgh; T. L. Lewis, president U. M. of A., Indianapolis, Indiana; and James O'Connell, vice-president A. F. of L., Washington, D. C. The committee will submit a preliminary report at the next session of the Mining Congress, at Goldfield, Nevada, September 27 to October 2. The absence of uniformity in the installation of electrical equipment in coal and precious metal mines has given rise to annoying problems, and the work of this committee will be watched with interest. Those having views to offer on the subject are invited to send them to Edward B. Rosa, chairman of the committee, care of the Bureau of Standards, Washington, D. C.

Coalite.

Coalite is a semi-coked coal, the manufacture of which had been introduced in England. It is the invention of Thomas Parker, a well known electrical engineer. It is a free-burning coke produced at a lower temperature than gas coke or metallurgical coke. It has very much the same characteristics as the metallurgical coke produced in earlier centuries before it was necessary to provide a hard coke capable of supporting the increased burden of a modern blast-furnace.

It has been feared that the monopoly claimed for it would be broken down by the want of novelty in the patents. On the other hand, the supporters of the process urged that though the novelty of the coke itself might be disputed, yet such coke had never before been manufactured in a by-product furnace and that the combination of the coke and the by-products made a novel and valuable process of manufacture. Experience during the last year has shown that the process as at first enunciated has required many modifications. At the present time the Coalite company is still experimenting at its plant at Wednesfield, near Birmingham. At Barking, in the East End of London, one unit of plant has been working for some months. A unit consists of 32 stills, each containing 12 tapered retorts, and its daily output is 33 tons of coalite, 250,000 cu. ft. of illuminating gas and 1000 gal. of tar. Four more units are in course of erection, and the first section of a distillery for treating the tar should be ready in a few months. Two units are being erected at Hythe, a town on the Kent coast, and gas will be supplied to the gas companies of Hythe and Folkestone, while the coalite will be disposed of locally, and the tar shipped to Barking for distillation. The most important installation in the Kingdom is probably that at Plymouth, where three units are now erected. The Plymouth gas company, to whom the gas is supplied, reports favorably on its illuminating power. At Barking it is probable that the gas will be used for power purposes. The tar is similar to ordinary gas tar or coke-oven tar. It is intended to make a specialty of a product called 'coaline,' which is practically benzine.

EDITORIAL.

FLOODS have been unusually disastrous in Colorado recently. Railway service has been seriously crippled, and it is probable the Durango smelter will have to close until tracks can be re-laid. This in turn will necessitate closing some, at least, of the mines. In the meantime Telluride gets its mail by stage, and the patient burro has again taken up the white man's burden.

LIQUIDATION of the debts of the Sierra Madre Land & Lumber Company is proceeding. The purchase of the holdings of Mr. W. C. Greene, amounting to 2,100,000 acres of pine-land, has yielded a sum which will relieve the financial tension produced by Mr. Greene's operations in the Western part of Chihuahua. The Greene Gold-Silver Company passed out some months ago, and we understand that the Greene Consolidated Gold Company has also fallen by the wayside. This is the last flicker of the Greene fire that burned so wierdly in northern Mexico, and even blinded President Diaz for a little while.

IT is with genuine regret that we chronicle the closing of Mr. Jesse Knight's smelter, which, with splendid faith in himself and the district he has done so much to develop, he built at Tintic, Utah, a year ago. The details appear elsewhere in this issue. Suffice it here to say that Mr. Knight and his friends have evidently sustained a loss of over a million dollars, and that the smelter will probably never be re-opened. Its failure illustrates anew the principle we have so often enunciated, that only on a large scale can smelting be economically conducted, and anything uneconomical is intolerable to the present age. We may lament the loss of sentiment, but this is an epoch of conservation of resources, and to produce at a high cost, when a lower one is possible, is as much a loss of national wealth as to let the forests burn up unimpeded, as they used to do in the good old wasteful days. The reason why Mr. Knight failed was that he could not feed his furnaces with his own ores, he could not contract a supply against competitors, save at a loss, and so the business went to those who could handle it most cheaply. The obvious lesson is, never start a smelter without ore enough of your own and profit enough demonstrable from the operation to give staying power while seeking to build up a clientele for custom work.

THE advance program for the Goldfield meeting of the American Mining Congress, September 27 to October 2, indicates that an unusually good meeting is in prospect. It is planned to devote the greater part of Tuesday to a general discussion of the silver question, to visit Tonopah Wednesday, to take up

problems relating to the general revision of mining laws on Thursday, and on Friday to have papers and discussions on the land policies of the Federal Government as they affect mining. Entertainment for the rest of the week has been liberally provided. While a large number of speakers have been given place on the program, the statement is made that "technical and descriptive papers will take second place to the practical discussion of live subjects upon which the action of the Congress is expected." This is exactly as it should be. The American Mining Congress is no place for the reading of technical papers. What is expected of it is discussion of the every-day problems of mining, particularly as relates to matters of public policy. It should help to formulate public opinion, and when the latter is determined should stand as its recognized exponent. This it can do by following the plan outlined. Too often public bodies of this sort suppress or misrepresent real opinion rather than the reverse. Open discussion harms no good cause, and we are glad to see the attitude the officers of the Congress have taken. The American Mining Congress has been steadily growing in dignity and power and is now, as it should be, a most influential organization. Mining men who take an intelligent interest in the larger problems of public affairs relating to their industry are supporting it, and year by year its influence increases. California will be well represented this year. Mr. W. C. Ralston, as chairman of the local committee, has arranged for a special train and a large number of members and delegates are going. The meeting bids fair to be one of the most important as well as most enjoyable of the year.

Edward Henry Harriman.

In the death of Mr. E. H. Harriman the country loses a man of phenomenal power. He stood for no academic principles of ideal manhood; he illustrated with striking force that saying of Emerson's, "nothing succeeds like success." He was one of a group of three towering figures in the economic ranks of American life. Mr. James J. Hill has been a builder of empires, a man who dared by the power of his genius to construct a great railway system across the continent, at once competing with hostile parallel systems, and having to develop the resources of a virgin country to furnish freight for his road; Mr. J. P. Morgan has shown himself an organizer superior to any who has loomed upon the financial horizon, a genius in the conception of bold designs, gifted in the delegation of authority, but one who troubled himself little about details. Mr. Harriman was a type distinct from these. He re-constructed, re-formed, augmented the work of others. He mastered detail, he directed policy. He was cognizant of the petty minutiae of management, and of the broad features of administration. His power lay in the creation of a perfect system, in producing efficiency, in daring to spend money in elaboration and betterment with such adequacy as to leave no weakness in the parts. Thus was the whole structure given harmony and strength.

Mr. Harriman has brought the East and the West closer together by his rejuvenation of the Southern

Pacific and the Union and Central Pacific systems. He may have taken all the traffic would bear, but he has given the nation vigorous arteries of communication; he has brought San Francisco within four days of New York City; he has rendered it possible to handle a tonnage over the transcontinental lines sufficient for the growth of the great West in population and affluence. He has sustained a steamship service on the Pacific which has been used as suited his plans, founded upon reasons which appeared to him economically justifiable. It will at least constitute the basis of a merchant marine which will ultimately dominate Oriental traffic. We may condemn the practices of these corporations controlled by Mr. Harriman, but we can easily believe that they were part of a process of evolution, leading along lines of practical efficiency to solid development for the future. Upon the foundation which he has laid a structure may be reared leading to greater popular good. Already it is clear that there is no Elisha upon whom the mantle of Elijah may fall. The master-builder is dead, and the power he wielded is divided among many men. Thus we see that one-man power depends upon the man. We believe in the ability of democracy to withstand the aggressions of a single individual. The modern financier has learned that greater profits accrue from increasing the individual's earning power than by reducing it. The principle of conservation applies to men as well as to forests and minerals. Hence the old doctrine of 'live and let live' acquires new force and fresh vitality.

We offer no excuses for Mr. Harriman's inflation of the indebtedness of the Chicago & Alton nor for his continuance of the iniquitous and debauching political machine created in California by C. P. Huntington. He was a modern Caesar in finance; he used any means, without scruple, to attain his ends; but he opened the way to larger prosperity. He has left a legacy of substantial progress from which the nation will benefit. Wherein his policies were anti-social they need not endure, if the people will perform their duty as citizens. There are two kinds of greed; constructive and destructive; Mr. Harriman represented the former, which is opposed to the mediaeval character of the other. He was at least modern—which is better than to be reactionary.

Reforms in Federal Mining Law.

The Federal mining law has stood without general revision since 1872. It argues well for the harmony of its parts that a legal structure should stand uncondemned by the architects for thirty-seven years. Meanwhile supplementary legislation has been enacted, and the courts have filled in the weak places with decisions giving solidity to the whole. It is questionable whether a general upheaval would not produce evil in excess of any good that might follow, but a sentiment favoring the attempt is so widespread that the matter will doubtless be given serious consideration by Congress within a year or two. The influence of the American Mining Congress in giving direction to thought and action upon this subject will be great, and the resolution which may be passed after hearing the report of the committee on revision

at the coming session in Goldfield will be watched with deep concern.

The so-called 'law of the apex', or that feature of the law conceding extralateral right, has been the chief object of ridicule and denunciation, and it is almost certain to be assailed, whether by recommendation of the committee or otherwise. It has been our opinion, consistently held, that the granting of the extralateral right was an unfortunate circumstance, because veins have a habit of departing from the simple geological prescription of the law-makers, because it is inapplicable to large masses and mineralized zones, and because of many irregularities in veins which often lead to complications too vexing to be settled amicably out of court, or so utterly insoluble as to compel compromise, which is but an escape from destruction whereby some one gets more and another less than he would be legally entitled to. The idea of a right to follow the vein on its 'dips, angles, and spurs', regardless of its wanderings beyond the confines of rigid boundaries, arose among those most theoretical of all men on earth, the plain 'practical' miners of the hills. The early Western miner theorized how a vein should be—a sort of ham-slice in a sandwich—and he insisted on having all the ham. Since it turns out that veins are not quite so simple as that, he would now return to the ways of his fathers and hem himself in by vertical bounding planes. This, however, would lead to such serious unsettling of present conditions, and would involve so many conflicts, that a change could only be succeeded by disastrous litigation, and plain common sense would incline one to leave well enough alone. It would, furthermore, involve many serious alterations in existing laws. In order to follow a vein in depth, under vertical side-line restrictions, it would become necessary to locate a much larger area, and in many cases this would require the appropriation under mining title of large tracts which at present would be adjudged agricultural land, hence not be open to location as mining claims according to present rulings, because actual discovery might not be possible by superficial exploration. It is assumed that no departure would be made from the principle which now gives to the miner the prior right in public lands, where the mineral character of the land admits of proof.

It would seem to be preferable to modify the law in detail rather than to risk the serious unsettling of conditions which would result from a general revision. There are, undoubtedly, many details which could be altered advantageously. As an example may be cited the system by which a locator may hold many claims for an indefinite period by performing annual assessment work. The purpose of the Government was plainly to compel development when a discovery had been made, but the method has failed of attaining that object. It results too often in tying up land without honest attempt at utilization. Annual assessment work should not be a means of maintaining possessory right alone; it should be a step in the process toward securing patent. The existing law requires that \$500 worth of work shall have been done on a claim before patent may issue. It has further become established by the courts that assess-

ment work is not required within the calendar year in which a claim was located. Hence it would seem reasonable to require that each year's assessment work should constitute a portion of the required \$500, and that before the end of the five-year period, which in effect may become practically a six-year period, application for patent should be made, or the claim forfeited. The object of the law should be to promote the development of industry under conditions of security, and these ends are reached through fixing a time limit within which proof of value or worthlessness shall be so completely ascertained that the possessor of inchoate rights in the claim shall either desire to perfect his title through patent, or be willing promptly to relinquish it. The law does not contemplate the granting of mining claims for the benefit of speculators whose ambition is to seek strategic positions merely for the purpose of compelling others to buy them out.

The administration of the Forest Service has accentuated other defects in the Federal mining statute. At present the Government theoretically is ignorant of the existence of mining claims, duly located and held by sufficient annual labor, until application for patent has been made, but the abuse of the right of location to acquire control of lands for the sake of timber and water-power has revealed the necessity of Governmental interference when evidence of fraud exists. On July 3 of this year the Department of the Interior decided that certain placer claims held by Mr. H. H. Yard and the North California Mining Company in Plumas county, California, were invalid. This action was taken in advance of application for patent. We objected to this proceeding at the time as being without strict warrant in law, and as representing a tendency to arrogate authority by elevating an administrative process to a rank parallel with the legislative. That such action seemed justifiable for protecting the resources on the public domain, from misappropriation, shows the need of remedial legislation.

There is a growing tendency to require demonstration of the validity of a discovery on mining claims, irrespective of application for patent. This certainly has full warrant of law. The statute says: "No location of a mining claim shall be made until the discovery of the vein or lode within the limits of the claim located." Nevertheless *pedis possessio* has been fully recognized, the possession in fact by the prior prospector being protected for a reasonable time so as to give him opportunity to continue exploration which may lead to a valid discovery of mineral. This is but reading justice into the statute to make it square with the expedencies of mining. The requirement of a discovery of mineral on a lode or placer claim as a condition precedent to valid location appears unnecessary. Indications of commercial mineral may exist, or conditions may logically raise a presumption of its existence within a certain area. It would be reasonable to recognize a form of right different from that of a mining claim, a privilege to hold a certain area for a limited period subject to investigation, within which time proof of the existence of absence of a vein, or of valuable alluvial deposits, might be ascertained, upon which to base a

formal location of valid claims. This principle is successfully applied in Mexico under the name of 'zoning'. As the law in the United States is now construed by some of the higher courts, at least, a locator who may have excellent reason to believe that his exploration will demonstrate the presence of valuable deposits is only protected to the extent needed to give him room for work and to prevent probable breaches of the peace; but while *pedis possessio* is thus protected it must yield to an actual location on a valid discovery made by one who has located peaceably without fraudulent purposes. The foresight of one man may thus attract others, who may achieve a prior discovery by mere accident. It therefore becomes a 'race of diligence', in which there is also a large element of luck.

Determination of the fact of discovery opens the possibility of arbitrary interference by the Government in a manner that requires sharp legal limitation. Lodes or placers may not be valuable under certain conditions of time and place, which under later conditions may acquire commercial importance. Indications of value should take rank to no small extent in accordance with the faith which an owner of a mining property displays in the continuance of development. The 'crazy Frenchman' of Talpujahua would have been ejected if he had been required to 'prove validity', but today the world bows to the wisdom of this same Mr. J. G. Fournier, discoverer of the famous Dos Estrellas mine.

The right of locating association placer claims requires closer restriction. The principle seems faulty. There is no more reason why eight men should hold an association claim and be permitted to do the amount of assessment work applying to a one-man claim one-eighth the size, than could be adduced for an individual to hold a similar group under like conditions. An association claim usually turns out to be for the benefit of a single man; why not permit him to locate it for himself originally, and preclude his locating other claims contiguous thereto? The ends of honor and public advantage might be better gained in this way, with the further requirement of personal performance of the acts of location, than under the present system. We have seen the abuse of the law in Alaska, where sequestration of large areas has been accomplished through wholesale location of association claims, the power of attorney having been used by individuals to a degree that has strained the patience of the people and the courts.

The rights of aliens also need re-consideration. The existing law leads to an absurd anomaly. The presumption of citizenship accords the privilege of location or of holding an unpatented claim, but the alien is prohibited from obtaining patent. He should certainly be given equal rights with citizens, or none at all.

We have not ventured to review more than isolated examples of defects in the mining law, pointing out deficiencies which might properly become the subject of legislation. These could be reached without radical revision of the fundamental law. An attempt at thorough re-construction of the statute would certainly be attended by grave difficulties and financial injury to the mining industry.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

PHILIP L. FOSTER is at Mexico City.

GELASIO CAETANI is at Ishpeming, Michigan.

W. J. BARNETT was in Spain during August.

F. L. RANSOME will be in San Francisco soon.

J. C. CORBETT has gone to Ventanas, Durango.

EDWARD H. NUTTER has returned from Alaska.

LEWIS T. WRIGHT has returned to San Francisco.

JAMES DOUGLAS has returned to New York from London.

J. H. CURLE has returned to London from a holiday in Norway.

EDMUND JUESSEN was in San Francisco, on his way to Los Angeles.

C. T. GRISWOLD, of Colorado College, is in Wyoming for the Forest Service.

STUART L. RAWLINGS has returned to San Francisco from San Dimas, Mexico.

C. H. MACNUTT has taken charge of the Ponderosa mine, at Coallahuasi, Chile.

R. J. FRECHEVILLE passed through New York on his return from Pachuca to London.

H. FOSTER BAIN has returned to San Francisco from an extended trip through Colorado.

C. H. POIRIER is now at the Republican mine of the Norman Mining Co., Jacksonville, California.

R. H. BUTLER has joined C. S. HERZIG and has gone to Nicaragua, leaving London on September 9.

WILFRED B. WAINWRIGHT, of Los Angeles, has gone to Josephine county, Oregon, to examine properties.

Obituary.

CHARLES GEORGE WARNFORD-LOCK, M. I. M. M., F. G. S., was the son of a mining engineer. He was born in Hampshire, September 9, 1853. He was educated at Cranleigh, and his first professional engagement was in the sulphur mines of Iceland. He was afterward engaged in alluvial mining in Hungary, and later held responsible positions as mine manager in the Black Hills of South Dakota and in New South Wales. It was in the latter country, in 1896, that he took charge of the Wentworth Gold Fields Proprietary Co.'s mines. While he was controlling affairs there a prolonged strike took place, and it was owing to his energy and determination that he was able to run the mines during the period of disturbance, and bring the strike to a satisfactory issue. Mr. Warnford-Lock also managed mines for the Bulawayo Exploration Co. at Gwelo, Rhodesia; and for the Raub Gold Mining Syndicate in the Malay peninsula. For some time he resided in Sydney, where he practised as a consulting mining engineer. He was the author of several well known works on mining and cognate subjects, of which the chief are: 'Practical Gold Mining' (1889); 'Mining and Ore Dressing Machinery' (1890); 'Economic Mining' (1895); 'Principles and Practice of Gold Milling' (1901); and 'The Miner's Pocket Book', which ran into five editions, the last being published in 1907. In that year he also brought out his last work, 'Mining in Malaya for Gold and Tin'.

Mr. Warnford-Lock was one of the original members of the Institution of Mining & Metallurgy, and served on its council and on its various committees. He moreover contributed several papers on mining and metallurgical subjects to the Transactions of the Institution; and he always maintained a keen interest in its affairs and well-being. He returned to Malaya in 1908, where he was engaged in inspecting and reporting on properties for various mining companies. An attack of ptomaine poisoning in the autumn of last year seriously impaired his constitution, and he was compelled to take voyages to China and Ceylon to recuperate his health. These were unfortunately unavailing, for after eight weeks severe illness he died at Bandarawella, Ceylon, July 30 last.

General Mining News.

ARIZONA.

COCHISE COUNTY.

The mine of the Bernoudy-Turkey Creek Mining Co., in the Paradise district, has been shut down on account of the lack of funds.—The Bisbee Extension Mining Co. has stopped cross-cutting and will sink the shaft an additional 100 ft.—The Lowell shaft of the Copper Queen company has reached the 1600-ft. level, and a drift started to connect with the Sacramento.—The Superior & Pittsburg company has commenced new development work on the tenth, eleventh, and thirteenth levels of the Cole shaft. The raise from the 1500 to the 1400-ft. level of the Junction shaft has been completed, and all the water is being pumped from the 1500-ft. level.—A cross-cut from the 850-ft. level of the Oliver shaft of the Calumet & Arizona Copper Co. opened a good body of oxide ore.

GILA COUNTY.

A body of sulphide ore was cut by the adit of the Rye Copper Co., 16 miles from Payson, when in 325 ft. The adit is being run to prospect the ground under a large iron outcrop, and will require about 700 ft. additional driving to cross-cut that portion of the country. H. S. Duncan is superintendent.—It is reported that the National Mining & Exploration Co. has raised \$100,000 to carry on development work by the issue of 6% first mortgage bonds.—The New Keystone Copper Co. has installed a 3-drill compressor and started a drift on the 300-ft. level. Cross-cuts will be run from the drift on the 150-ft. level and started from the 300 when the drift there is well under way. The Keystone drills have completed 11 holes through ore assaying from 1½ to 2½% copper.—The Cole Development Co. has taken over the old Cole & Goodwin property, 12 miles southwest of Globe. There are 17 claims in the group which has been developed by a 325-ft. shaft. This opened a body of chalcopryite ore that assayed from \$3 to \$10 gold. The plan is to deepen this shaft and cross-cut to the ore.

GRAHAM COUNTY.

The Moore & Underwood lease, on the Copper Cliff claim, in the Clifton-Morenci district, has been purchased by Walter Doudna and L. T. Bridgers, who are shipping a small amount of ore.—The road from Clifton to the Gold Belt mine is being repaired, and a site for the new mill graded. The contract calls for the delivery of the mill by the first of November, and the company expects to complete the installation this winter.

MAHICOPA COUNTY.

Ten stamps are dropping in the Vulture mill, near Wick-enburg. The steam-power plant was recently replaced by a gasoline engine which has proved so satisfactory that a second one has been ordered, and ten more stamps will be started as soon as the new engine is installed.—A number of stockholders of the Golden Mining Co. visited the property at Golden recently to determine the most advantageous method of treating the ore. There is a 10-stamp mill and cyanide plant at the mine.

MOHAVE COUNTY.

The mill at the Gold Road mine will be completed in a short time, and will be started on ore from the fifth level. There is a large force of men at work in the mine blocking out ore preparatory to the starting of the mill.—L. D. Godshall has bonded the Winchester Fraction and Jubilee claims in the Wallapai district.—The adit at the Red Gap property, in the Weaver district, cut a 10-ft. vein of \$20 ore. D. S. Richards is in charge of the work.—At the Carter mine the shaft is down 190 ft. On the 200-ft. level a station will be cut and cross-cutting started toward the vein.

YAVAPAI COUNTY.

The shaft at the Leghorn mine, on Cherry creek, is to be sunk from the 485 to the 1000-ft. level as the result of the satisfactory operation of the Lane mill recently installed at the mine. A number of stockholders have visited the property lately, and it is understood that money will be

raised shortly to open the adjoining claims owned by the company.—A Nevada company has secured the group formerly operated by Richard McNary in the Copper Basin district, and will prospect several veins of cinnabar that are known to exist on the property.

CALIFORNIA.

MONO COUNTY.

A number of oil seepages in Bridgeport and Bodle canyons, five miles northwest of Mono lake, have caused considerable excitement in that neighborhood and 1280 acres of land have been located.

NEVADA COUNTY.

The drift on the eighth level of the Delhi mine, north of Columbia, opened a shoot of rich ore. The vein is 4 ft. of blue quartz, containing free gold and seams of arsenical pyrite. From the sixth level a cross-cut to the west vein opened a good grade of milling ore under the McMurray shaft giving 200 ft. of backs. Hamilton Eddie is superintendent.—A small force of men is at work in the upper levels of the Kenosha mine, but it is understood that money has been raised for development and that the company will sink to the 800-ft. level and explore the vein from that point.—A new 10-drill compressor has been installed at the Golden Gate mine.—An extension of the bond on the Native Son mine has been granted to J. H. Bishop. The adit has been driven 200 ft. toward the vein, and it is estimated that it will require 600 ft. more driving to open the ore.—The hoisting-plant at the Orleans mine has been purchased by the Dana company, and is being hauled to its property near the Idaho-Maryland mine. The shaft will be sunk to the 800-ft. level, and cross-cuts run to the vein each 100 ft. Charles B. Smith is in charge of the work.—Edward I. Field has secured a bond on the Gold Mound mine at Deadman's Flat. A shaft has been sunk 160 ft. on the property and the vein opened in several places. Mr. Field will install a compressor and sink to the 300-ft. level before cross-cutting.

PLACER COUNTY.

W. B. Pendleton is opening the old Laird mine east of Loomis.—The shaft at the Lunkens mine is down 100 ft., and is expected to cut the vein any time.—Operations have been resumed at the Star mine.—U. S. Fletcher has made a payment of \$25,000 on the Home Ticket mine, leaving a balance of \$17,000 due on the property.—The Imperial Mining Co. is putting in a new dam at its property above Auburn, and has contracted for a supply of lumber to repair the flume.—The cross-cut on the Black Oak extension, near New England mills, opened a vein of free-milling ore.

PLUMAS COUNTY.

A lower adit is being run on the Del Monte mine.—An 8-ft. vein of \$15 ore was opened by H. H. Hunter on the Owens & Carter property near Seneca.—A 30-ft. shaft has been sunk on the Hewitt claims, and drifts run 160 ft. on the vein. An interest in the claims has been sold to further develop the property.—R. A. Costar, of Prattville, has leased the Sunny Side gravel mine for a company and will drive a bedrock adit to drain the channel.—E. H. Kelley has taken 200 tons of ore for a test run from the Rose mine on Poorman's creek.—Lessees on the Crown Point group, 12 miles east of Quincy, have been milling \$55 ore.—John Taft, of Quincy, is preparing to erect a 5-stamp mill on his group on Crescent hill.

SAN BERNARDINO COUNTY.

Work has been resumed at the Jumbo mine and cross-cutting continued in the big vein. Thirty feet of ore has been opened that assays over \$30 per ton.—On the Oro Belle property the shaft is down 370 ft. A station will be cut at the 400-ft. point, and if sufficient water for milling is not found, the company will install a diamond-drill to sink for water.—The Hart Townsite Co. has uncovered an 8-ft. vein on the Red Boy claim, and is to sink a shaft to prospect the property.

SHASTA COUNTY.

G. M. Sleezer is shipping \$24 ore from the National mine, three miles north of Buckeye, to the Mammoth smelter at

Kennett. The property was formerly known as the Forbes mine, and was equipped with a mill and cyanide plant. The shoot was lost and the mine abandoned after considerable money had been spent in prospecting. Mr. Sleezer re-located the property and has lately succeeded in opening payable.—The Joshua Hendy Iron Works has attached the machinery at the Black Tom mine, at French Gulch, pending the decision in a suit for money due on machinery.—The Balaklala Copper Co. has employed J. W. Blankinslip, professor of botany, at the State University of Montana, to investigate the damage done to the orchards in the vicinity of the smelters. Mr. Blankinslip was the horticultural expert in the smoke cases at Anaconda and Butte, so is well equipped to take up the investigation of the damage done in Shasta county. Alfred Sutro, of San Francisco, addressed a meeting of the Shasta County Farmers' Protective Association at Anderson, requesting them to postpone any action until the first of November. As there was no regular list of members, no action was taken, as it was a question of who was eligible to vote.—C. M. Clark and W. W. Rees have taken a bond on the Whisky Creek group of claims, near Whiskytown. Clark & Rees have put several miners at work on the property and expect to build a small mill to test the value of the ore.—The adit at the Spread Eagle group, above Copley, cut a body of copper sulphide ore. The company is to install a compressor and drills shortly. W. C. Onn is secretary of the company.

SIERRA COUNTY.

Walter Bell has bonded the Blue Banks claim of John Reid and commenced operations.—Charles W. W. Meckin has succeeded Mr. Mather as superintendent of the Croesus, better known as the Plumbago mine.—The adit of the Slate Castle-Jaffa mine cut a rich stringer of arsenical sulphide ore.—Several loads of machinery have been hauled to the Cleveland mine, between Sierra City and Downieville. W. R. Warton is in charge of the work at the mine.—At the Brandy City gravel mine 40 men are working on the flume and dam, and a bedrock adit is being driven to drain the channel.—Hood & Breise have let a contract to haul lumber for the boarding-house at the Bunker Hill property, on which they have taken a bond.—The adit at the Gray Eagle mine, at Gold Point, opened a 6-ft. vein when in 1040 ft. The ore assays \$68 per ton, and was cut 400 ft. below the outcrop.—Lutz, McMahon & Gambrina have cut the vein in the Roasco property, three miles west of Downieville, which they are opening under bond.—The mill at the Red Star mine, near Alleghany, has been completed. There is a large amount of ore blocked out in the mine that will supply the mill for several years.—A rich lead of blue gravel has been opened in the Omega mine near Forest. Several cross-cuts have been started through the gravel. The bedrock is a soft serpentine, and the boulders are small, not over a foot in diameter.

TUOLUMNE COUNTY.

James E. Conde has secured an injunction restraining the Parlin Mining Co. from removing the machinery from the Driesam mine which it has been operating under bond.—The Yrma Mining Co., which is operating the old Josephine mine, near Algerine, under bond, is running a lot of ore from the old dumps through a Huntington mill. The ore assays \$8 per ton, and it is the intention of the company to add a 5-stamp mill to its equipment.—The ore recently opened by the cross-cut from the 400-ft. level of the Central shaft of the Soulsby mine, is averaging \$100 per ton.—In the Knights Creek district William Faller has opened a 9-ft. vein with a foot of high-grade ore on each wall.—On the Gold Bug claim a shoot of \$50 ore has been opened.—Rufus George is storing ore on the dump, preparatory to a test run.—A new vein of free-milling ore has been opened in the Excelsior mine, near Confidence, while prospecting for the old vein. James Conde is in charge of the work.—A test run of samples has been taken from the Gem mine to determine the value of its orebodies.—Newkirk & Conlee are operating the Mansfield gravel mine, on Woods creek, under bond.—R. A. Nicholls has succeeded in finding the vein at the Draper mine. The property has been a good producer in the past,

and it is reported that the vein now opened is as rich as in former days.—In the Albany mine, under bond to the Erie Mining Co., a shoot of rich ore was opened on the 700-ft. level. The vein at this point is 4 ft. wide.

YUBA COUNTY.

The committee recently appointed to investigate the action of the dredges, spent a day in the Marigold district. Next week they will spend a couple of days near Oroville with representatives from Yuba, Butte, and Sutter counties.

COLORADO.

BOULDER COUNTY.

The Primos Gold Mining Co., near Nederland, has let contracts for the construction of a 10-stamp mill. The stamps will weigh 1000 lb. each, and the pulp will be treated on Frue vaners and a canvas plant.

CLEAR CREEK COUNTY.

(Special Correspondence).—The new strike which was made in the Capital adit is proving fully up to expectations. After driving through vein matter for 20 ft., several streaks of galena have been cut that assay as high as 200 oz. silver per ton. This vein, which is supposed to be the extension of either the Colorado Central or Ocean Wave, was intersected at a depth of 2200 ft. from surface.—Conti & Co., leasing on the fourth level of the Smuggler on Brown mountain, have shot into an 8-in. streak of smelting ore, and a mill-run a few days ago was settled for on the basis of 500 oz. silver per ton.—A streak of ore 6 in. wide has just been cut in the breast of the Vesper adit on McClellan mountain. Assays are from \$60 to \$70 per ton in gold, silver, and lead. G. W. Crump is manager.—A gasoline hoist to lift timber in the raise has just been installed at the Scepter adit on Democrat mountain.—N. Anderson, leasing on the Seventy-Three mine, shipped two classes of ore last week, the first grade bringing 758 oz. silver per ton, 40% in lead, and 7% in zinc. The second-class milled 478 oz. silver per ton, 20% in lead, and 3% in zinc.—The adit being driven into Griffith mountain by L. Hoery & Co. is in 325 ft., and will cut the Tom Reynolds vein 125 ft. below the surface workings. From the upper levels ore has been taken that assayed as high as \$15,000 per ton gold and silver. Work at that point was suspended about two years ago owing to the water that had to be contended with.—E. Butts, manager of the Columbia, shipped a carload of ore last week that was settled for at \$48 gold, 22 oz. silver, with 4% copper per ton. Work has been started on the new adit which will open 400 ft. of additional stoping ground.—A strong company has been organized to develop the Hidden Treasure group of mines on Lincoln mountain, and machinery is now being delivered on the ground. This property was one of the early-day heavy producers, and is credited with having produced the richest ore ever mined in that locality.—The Conqueror M. & M. Co., operating on Covode mountain, is employing a large force of men. A heavy tonnage of ore is being mined, the majority of the product being sent to the 50-ton mill for concentration.—A rich discovery was made on the Mint property a few days ago, an 8-in. streak of ore having been cut in the breast of the adit that assays \$160 gold per ton.

Georgetown, September 14.

CHAFFEE COUNTY.

An orebody assaying several hundred ounces in silver per ton was recently cut in the May S. mine near Granite, and a shipment of 30 tons sent to the smelter. W. E. Smith is in charge of the work.

GILPIN COUNTY.

The German Gold & Uranium Mining Co. has cleaned out the old German mine on Quartz hill, and sampled the face of the drifts. The vein on the 250-ft. level is 6 in. wide, and assays over \$1000, while on the 120-ft. level it is 5 in. wide, and assays \$90 per ton. The ore is all of a smelting grade as it contains considerable silver and copper.

GUNNISON COUNTY.

At the Enterprise mine, near Dorchester, the company is installing a 300-hp. hydro-electric plant to operate the compressor being erected at the mouth of the adit. The com-

pany is also building an aerial tram to carry the ore from the mine to the mill.—J. A. Norwood shipped a trial lot of ore to the Modern smelter in Denver and has another shipment ready for the Kuenzel smelter in Buena Vista.—Harrison & Chapin, operating the Maple Leaf mine, at Sillsville, on a lease, bought the mill and surface improvements on the property.—The Raymond mine is being cleaned out so it can be sampled.—A shaft is to be sunk 100 ft. on the Morning Star property, at White Pine, and the vein cross-cut from that point. J. C. Reagan is the owner.

LAKE COUNTY.

The Ontario property in the Twin Lakes district is shipping regularly to the smelter. A recent shipment netted the company \$500 per ton.—Work is to be resumed on the Aurora ground in Iowa gulch at an early date.

OURAY COUNTY.

At the Atlas mine the work is confined to development, the mill being started at intervals to crush the ore when enough has been accumulated for a run.—The Bachlor mine has been unwatered to the second level and the company is opening a body of gray copper ore. A contract has been let for the re-building of the flume, and it is understood that the mill may be started soon.—The adit of the Old Lout mine in Poughkeepsie gulch has been cleaned out and re-timbered and the company is preparing to prospect a number of veins upon which no drifts have been run.—A picked sample from the Uncle Sam No. 2 claim ran 33% copper and 13 oz. silver per ton.—The hoist at the Legal Tender has been completed and work commenced in the shaft.

SAN JUAN COUNTY.

It is reported that the Silver Lake mine in the Silverton district is to resume operations in October on company account. There has been a small amount of work done by lessees since the company stopped work last fall.—C. P. Hall, superintendent of the Gold Queen mine near Gladstone, is authority for the statement that the company will continue operations by hand work the remainder of this year and install a complete power plant in the spring.—The mill at the Peerless San Juan is to be completed this month. The tramway from the mine to the mill has been started and a large amount of ore stored on the dump in anticipation of the starting of the plant.—The Robert Bonner mine on South Lookout mountain was sold to the Lutz Mines Co., of Pittsburg, by George H. Barnes and Mrs. G. H. Stoiber. The property has a good record for past production, and under active management should be a steady producer. G. Crossmann is in charge of the property for the new owners.

SUMMIT COUNTY.

The Wellington mill, near Breckenridge, was shut down for a couple of days to install some new machinery. A number of ore-buyers are trying to contract for the Wellington output but so far the management has not seen fit to sign for any definite amount.—The Puzzle-Ouray mill has been remodeled and is running on ore from the mine. J. Safford is in charge of the work.—The Blue River Excavating Co. is drilling its ground near Breckenridge to determine its value for dredging.

TELLER COUNTY.

The Colorado-Victor Investment Co. is installing an electric hoist and compressor on the Rigi group on Battle mountain. The company has opened ore that assays from \$25 to \$30 per ton on three levels.—Lessees on the mines of the Granite Gold Mining Co. shipped 100 cars of ore during August to the Standard mill of the United States Reduction & Refining Co., at Colorado City. The ore averaged \$30 per ton.—The Portland Gold Mining Co. has opened a rich body of shipping ore on Battle mountain.—Allen L. Burris has secured an option on the controlling interest of the stock of the St. Thomas Gold Mining Co., which owns the St. Thomas claim on Bacon hill.—G. A. Hopkins and associates have leased the Bent shaft of the Mollie Kathleen mine and are installing a compressor and hoist.—The Free Coinage Gold Mining Co. has leased the Wilson dump to A. Bergenstressor.—A New York syndi-

cate, represented by Mr. Cohen, has secured a bond and lease on the properties of the Manhattan Gold Mining Co., on Bull and Ironclad hills, and will equip them with new machinery.—A trial lot of one carload of ore was shipped from the Jefferson mine in Victor.—The Half Moon Leasing Co. has been organized to open the lower shaft of the old Half Moon property. The shaft has been re-timbered and the drift thoroughly sampled, showing a good grade of shipping ore.—A shoot of rich ore has been opened on the 1100-ft. level of the American Eagle mine and operations resumed. Paul Hines is superintendent.

IDAHO.

BONNER COUNTY.

The Swastika Mining & Milling Co. has taken over a group of 10 claims near Lakeview and will drive a 3000-ft. adit to open the ore. It is understood the company is to install a concentrating plant at Sandpoint.

IDAHO COUNTY.

A 450-ft. adit on the George group has cut ore giving 300 ft. of backs. The vein is from 5 to 8 ft. wide on the surface.—On the John Mackey claims the 300-ft. cross-cut has cut a vein a portion of which is free-milling and a portion base. The vein is 15 ft. wide and has been traced for 2000 ft. on the surface.

OWYHEE COUNTY.

Arrangements are being made to re-open the old Trook & Jennings mine on War Eagle mountain. A good body of ore has been opened on the property, but little further work done, as the title has been in dispute.—A new orebody has been opened at the Pauper property.—The Arastra mill is running on ore from the claims of Louis Sorrenson. The ore is free-milling and a good clean-up is expected.—The Silver City Mining & Milling Co. has made the connection with the wires of the power company and is now working in the adit.

SHOSHONE COUNTY.

At a meeting of the stockholders of the Nabob Mining Co. at Kellogg it was decided to increase the stock of the company from \$1,000,000 to \$1,500,000 to provide funds to carry on the work. There is a 365-ft. shaft on the property with a 125-ft. drift from the 100-ft. level which was driven on a vein that was from 1 to 4 ft. wide. A lower adit has been started that will give nearly 500 ft. of backs.—On the Best Chance property between Osborne and Kellogg an adit is in 185 ft. and is expected to cut the vein in a short distance.—A trial shipment of one ton of zinc ore was sent from the Montana Standard mine, 10 miles east of Burke, to the reduction works at Joplin. When the best method for treatment has been determined a plant will be erected at the mine.—The mill at the Hercules mine was completely destroyed by fire on Labor Day, with an estimated loss of \$100,000. The mill was idle on account of the holiday and the origin of the fire is unknown.—A 30-in. vein of gray copper ore was cut by the raise from the second level of the Mineral Point mine south of Osburn. A winze has been sunk on the ore from the first level, opening the shoot for 120 ft. The mine is a short distance from the O. R. & N. tracks and has shipped 40 cars of ore to the smelters.

MISSOURI.

JASPER COUNTY.

(Special Correspondence).—An important sale was made last week when the 45-acre lease of the Granby Mining & Smelting Co. at Oronogo was bought by H. Tonkin and associates. Members of the same company are operating the Pinnacle. A face of disseminated ore 10 to 16 ft. high has been opened in the drifts.—At the Walnut Grove west of the Pinnacle a 14-ft. face has been uncovered at 200 ft. A second shaft is to be started at once and a 300-ton mill built.—Another important sale was made this week when the Excelsior Mining Co. bought of the Leonard Realty Co. over 1000 acres scattered over the district, principally near Oronogo and Galena. The company will develop the lands and then turn them over to lessees for operation.—One of the richest pockety formations now being worked in this district is the Katherine, northwest of Joplin. An upper run has been worked at 135 ft. and drifts are now being opened

at 165 ft. The ore is galena and zinc-blende.—The McGee Mining Co. at Duenweg has been running almost continuously for two years and has produced over 2500 tons of ore. There is still enough ore in sight to run the mine two years. Up to the present time hand-jigs have been used to clean the ore, but henceforth much of it will be cleaned on rougher and cleaner jigs.—A rich body of zinc ore has been cut in Lone Elm Hollow by W. I. Rusk while drilling prospect holes.—Forty feet of rich blende and galena was cut in a drift which was being run at the 60-ft. level in the Tim McCarty shaft in Chitwood.—Myers and Boyd, in Carl Junction, opened 20 ft. of galena ore.—In various parts of the district there are many drill rigs at work and several good discoveries are reported. Four drill-holes have been completed east of the Quick Seven in the Neck City camp, three of which cut good sheet ore from 170 to 215 ft.—A 40-acre tract of the Elliot & Zimmermann lands south of Webb City is being drilled.—An important find was made in the vicinity of Reeds by the Ishpeming Mining Co. in a drill-hole. The ore was struck at 45 ft., continuing to 77 ft.—S. Y. Ramage is planning the early erection of a 300-ton plant on his lease north of Webb City. The ore under development is 29 ft. high and occurs at 150 ft. The deposit is well blocked out by drill-holes and prospect drifts.—The Gouverneur Lead & Zinc Co. has just completed a 200-ton plant at Sherwood.—Bradley & Co. will build a mill on the Connor & Phelps land at Central City.

Joplin, September 11.

MONTANA.

MISSOULA COUNTY.

The Denver & Rock Island Development Co. is to sink a double-compartment shaft on the vein of its property near De Borgia. J. L. Presnol is manager.—On the St. Lawrence group near Salt Lake a rich discovery of copper has been made. The vein is 10 ft. wide and a drift has been run along it for 1200 ft.—At the Tarbox mine a winze has been sunk 200 ft. from the face of the east drift giving a depth of 600 ft. on the vein. This is 40 ft. wide and is a good grade of galena ore. It is probable that a concentration plant will be erected shortly.

NEVADA.

ESMERALDA COUNTY.

(Special Correspondence).—The Coalition and Queen companies have concluded a deal for the King-Heisner mill.—The Queen Mines Co. has acquired a large interest in the plant of the National Ore Purchasing Co., and the mill will hereafter operate exclusively on ore from the Queen estate. This will enable the big property to commence production on a large scale, as it now controls excellent milling facilities.—The ore-bins at Kearns No. 2 have been completed and a steady production will commence at once.—A 5-ft. body of shipping ore is being developed on the 100-ft. level of the Gold Dollar group. A. L. Bolson is the owner.—A new hoist has been ordered for the McMann lease.—The 12-hp. gasoline hoist purchased from the Mint-Coalition Extension has been installed by the Bridges-Daniels lease.—The Lawyers lease has commenced a raise for ventilation. As soon as this is completed work on the big vein will be resumed.—The Victor Consolidated is extracting \$18 ore from the Victor and Proskey leases on Coalition and keeping the recently acquired Murray mill running at full capacity. A cyanide annex will be added in the near future. Rawhide, September 10.

An orebody 12 ft. wide has been opened in a stope on the 425-ft. level of the Combination Fraction. The ore assays \$140 per ton and extends to the 300-ft. level.—The management of the Consolidated company is preparing to open the Combination and Red Top veins as 'glory holes', and it is probable that the capacity of the mill will be doubled to handle the increased output.

LINCOLN COUNTY.

The cross-cut on the 900-ft. level of the Mendha mine opened 15 ft. of ore, 4 ft. of which assays 25% lead, 25 oz. silver, and \$20 gold per ton.—The shaft at the Prince Extension near Pioche has been stopped at a depth of 75 ft. till the company can install a hoisting plant.

NYE COUNTY.

The station has been cut at the 1500-ft. level of the Mizpah shaft of the Tonopah Mining Co., and the guides are being put in from the 1200-ft. level down. In the east drift on the 340-ft. level of the Silver Top shaft the cross-cut has been stopped when in 360 ft., as the face is in andesite.—The winze from the 1100-ft. level of the Tonopah-Belmont mine is down 116 ft. on the vein, which is 12 ft. wide at this point and of milling grade. A station will be cut here and cross-cuts driven to explore the stringers in the hanging and foot-walls.—At a report to the stockholders of the Montana-Tonopah Mining Co. it was stated that the company had completed the payments on its mill and has a cash balance in the treasury, also bullion and concentrate in transit valued at \$80,000.—At Round Mountain the Gibson lease on the Blue Jacket property opened a pocket of ore that ran \$60 per pound. On the Morgan-Stofelt-Cook lease a drift is being driven west from the shaft to tap the rich ore opened on the surface recently.—The Manhattan Thanksgiving Mining Co. is to install a sinking pump at the 350-ft. level and sink to the 500.—The new mill of the Crystal Bullfrog in the Bullfrog district effected a saving of 73% of the assay value on the plates in a trial run on 50 tons of ore from the Denver property.—The Bullfrog Mayflower Consolidated company has resumed work in the Starlight shaft, which has been idle for two years.

WHITE PINE COUNTY.

The Coppermines company has given two new leases on its holdings north of Lane City. R. H. Richardson has a lease on the Isaac mine and F. C. Williams on the Union property, each lease running a year. These mines were active producers 25 years ago.—The shaft of the Boston Ely is in ore that averages 2% copper.—At the Ely Central the company has completed a blacksmith shop and surface plant preparatory to sinking on the Clipper group.—The Cole-Ryan representatives purchased the Rickard-Ely, Veteran, Extension, Giroux Extension, and Blackfoot groups in the Ely district.

NEW MEXICO.

GRANT COUNTY.

George and Noah Hoydon have leased the Volcano mine from C. R. Smith and are preparing to ship to the Douglas smelter.—By the addition of a 375-hp. engine to the power plant of the Socorro Mines Co. the company has power for its present requirements and enough additional to run an extra unit that the management is planning to add to the mill.

LINCOLN COUNTY.

The Parsons group near Nogal has been sold to satisfy a mortgage of \$120,000, held by J. H. Fuller for cash advanced to develop the property.

OKLAHOMA.

OTTAWA COUNTY.

The Clear Creek Mining Co. has been doing some extensive development and prospecting work in Mays and Cherokee counties east of Tahlequah, and are very optimistic concerning the finding of a rich lead and zinc field in the valley of Clear creek. One shaft has cut ore at a depth of 30 ft.—The Ottawa Mining Co. will begin work at once on the McNaughton tract at Miami. It is the plan of the company to develop not only the lead and zinc of this lease, but also to prospect for oil and gas.—The Miami Amalgamated Co. has sunk a shaft upon its lease into the same run worked by the Old Chief. There are also several other shafts down; in one the ore is from 100 to 200 ft., in a second from 92 to 127, and in the third from 120 to 132 feet.

WASHINGTON.

OKANOGAN COUNTY.

(Special Correspondence).—The Owasco Gold Mining Co. is applying for a United States patent on the Cobbler, Great Wonder, Similkameen, and Ufford claims, in the Similkameen district, near Oroville.—The Number One mine, on the summit of Little Chopaca mountain, two miles west of Nighthawk, has a vein 30 ft. wide and traceable 2500 ft. The ore assays from \$2.80 to \$149 per ton in silver and

lead, with a small amount of gold and copper. The average value is said to run between \$35 and \$45 per ton. Work will soon be resumed under the management of Chas. A. Andrus, when the shaft will be sunk to the 200-ft. point, and drifts run on the 100, 150, and 200-ft. levels. An electric hoist and other equipment will be provided. New buildings are being erected, under the supervision of Chas. A. Andrus, at the California mine.—A 4-ft. vein, assaying \$26 in gold, silver, and copper, is being stripped on the Bertha and Earl group, on the east spur of Mount Chopaca, and \$10,000 has been raised to drive an adit 400 ft., which is expected to tap the vein at a depth of 1000 ft.—The machinery for the Golden Sands Mining Co.'s placers, two miles from Oroville, will consist mainly of an electrically driven pump. The company has spent several years prospecting the property to prove its value for hydraulicking.—There has been considerable development at the Arlington mine, in the Ruby camp, and about two weeks ago a 40-ft. vein was intersected, since which assays have been reported to run as high as \$105 in gold, silver, and copper. The mine is being put in shape to increase the working force at an early date. An office building and a new boarding house will be erected near the mine.

Conconnully, September 13.

SPOKANE COUNTY.

Members of the Spokane branch are making elaborate arrangements for the entertainment of the American Institute of Mining Engineers, in Spokane, September 27 to 30, when the branch of western Canada will also meet in this city. The executive committee in charge is composed of C. P. Robbins, J. C. Ralston, Henry Kehoe, and L. K. Armstrong, editor of the *Northwest Mining News*. It is expected the Eastern engineers will visit the Coeur d'Alene district on the way to Spokane. There will also be delegates from Montana, Idaho, Washington, Oregon, British Columbia, and Alberta. The mineral exhibit at the Spokane Interstate fair, September 20 to 25, will be held intact for the inspection of the visitors, and an effort will also be made to have the mining companies in the northwest co-operate with the Spokane Chamber of Commerce in making one of the finest permanent mineral exhibits in the world.

STEVENS COUNTY.

(Special Correspondence).—In Orient district the First Thought mine has resumed shipping ore, after the straightening out of some matters pertaining to transportation and treatment, which required adjusting, and 50 tons per day of ore will be shipped to the British Columbia smelter, at Greenwood, B. C. A diamond-drill has been delivered and will be operated in prospecting the mine.—In the Valley Dew mine some workings near the surface have opened a pay-shoot, which appears to increase in value with depth. An adit is in 86 ft., and a contract has been let to extend it 350 ft., which will give a vertical depth of about 300 ft. below the upper workings.—A bond has been given on the Riverside claim to John H. Arnold, a lawyer of Columbus, Ohio, for \$16,000. The payments to extend over two years. The mine is situated near Rockcut. It will be equipped this fall with a concentrator.—In the Superior Copper mine, six miles west of Chewelah, the ore-shoot struck last fall is widening as depth is obtained. The vein is now 7 ft. between walls. An adit has opened it to a depth of 100 ft., where four stringers of good ore are exposed, varying from 4 to 7 in. in width, and assaying in gold, silver, copper, and lead, and a small percentage of tungsten is reported. Silver and copper predominate. J. D. Boone is superintendent. This company may soon be in the market for machinery.

Chewelah, September 14.

CANADA.

YUKON.

(Special Correspondence).—J. H. Conrad has just bought and shipped from Vancouver, B. C., three steam boilers and three air-compressors for installation of one plant each on the Big Thing, Dale & Fleming, and Montana mines, situated in Windy Arm district, near Carcross; also a Riblet aerial tramway for the Dale & Fleming. It is stated that the Venus mill is now in operation.

Vancouver, September 14.

Special Correspondence.

LONDON.

White Lead Competitors.—Dolcoath Prosperity. — Elmore Vacuum-Plant.—Broken Hill Proprietary.

For some years there has been agitation in France against the use of white lead, and a month or so ago the Senate confirmed a resolution passed previously by the Lower House entirely prohibiting its employment. Consequently the claims of zinc white, lithopone, and other substitutes are being pressed by their sponsors. In particular, lithopone is receiving special attention, and incidentally is providing the London promoters with a new field of operation. This week the shares of a company called the Anglo French Chemical Works, Ltd., have been offered to the public. The object of the company is to acquire the works situated at Vireux in the Ardennes, France. Lithopone is practically unknown in England, although some small amounts are imported. It was originally made in Germany, though an earlier form, from which the idea sprung, was invented in England. It is now manufactured in France, and in the United States, at the Palmerton works of the New Jersey Zinc Co. Lithopone consists of zinc sulphide and barium sulphate, and is produced by the reaction between barium sulphide and zinc sulphate. The one drawback to its use is its tendency to blacken on exposure to bright light before it is dry. For this reason it is not likely to be largely used by painters, though it has applications in the enameling of furniture and other articles.

The details of the present position of Dolcoath have come to hand. The state of affairs at this mine is of unusual interest, proving once more that tin veins are worth following in depth. For some years it has been the opinion of the manager, R. Arthur Thomas, that developments at depth were placing the mine in an extremely favorable position, and warranted the sinking of a new main shaft to meet the incline shaft at about 2500 ft. In connection with the sinking of this shaft a strange event occurred. The consent of the landlord, Mr. Basset, had to be obtained before the new work could be undertaken. He consulted a firm of colliery engineers in South Wales with regard to the shaft, and he insisted on the adoption of the shaft recommended by them. Consequently there is a brick-lined circular shaft, such as is seen in collieries, passing through the hardest granite. The shaft is now down 2541 ft., and will connect with the 2640-ft. level in a few weeks. The ground in this neighborhood has turned out to be rich in many places, and ore containing 100 lb. of black tin per ton is not uncommon. It has been possible during the last half year, January to June, to increase the output of concentrate, and at the same time to reduce the amount of ore mined. In this way the manager has been able to transfer some of the labor from mining to development, without reducing the output or increasing the costs. The ore raised during the six months was 45,880 tons, which is about 4000 tons less than the half yearly average, while the concentrate sold amounted to 1000½ tons, as compared with an average of 850 to 900 tons during recent previous half years. It is not since the last half of 1901 that the half yearly output reached four figures. The produce per ton was 48.85 lb. of concentrate, as compared with from 38 to 40 lb. during the last six years. In 1895, when the mine was acquired by the present company, and additional capital for plant subscribed, the half yearly output was just over 1000 tons of concentrate from 28,000 tons of ore. This was an extraction of 79 lb. per ton. Unfortunately the tin market was in a wretched state in those days and the average price received for concentrate was only £39, so that the amount realized was only £39,769. Under the new régime, the amount of ore raised was gradually increased and at the same time the grade dropped. During the last half of 1901 the ore raised had been increased to 50,000 tons, and the content had fallen to 47 lb., so that the output was still just over 1000 tons. On the other hand, the price had risen to £70, so that the amount realized was about £70,000. Since 1901 the ore raised has

been practically constant, but the produce dropped to 40 lb. and lower. During 1906 and 1907 the boom in the price of tin brought the income to over £100,000 for the half year, and some good dividends were paid. The working profit for the first half of 1909 was £20,178, out of which £5351 went for royalties, and £1889 for income tax. A dividend at the rate of 5% per annum absorbed £8500. Other interesting items of news are that copper ore obtained from the Elmore vacuum-plant is now being sold, and that 12 heads of air-cushion stamps are to be erected in place of the old Cornish stamps still remaining as a relic of by-gone days.

The labor troubles at the Broken Hill Proprietary have had a disastrous effect on the company's financial position. The report for the six months ended May 31 shows a loss of £59,000, and £129,837 has been withdrawn from the reserve fund and placed to working capital once more. During the half year, the mine and smelter were working for only five months, and only 17,936 tons (some of it purchased ore) were smelted at Port Pirie, as compared with 132,979 tons during the previous year. The production was 438,109 oz. silver and 7609 tons of lead. Owing to the award of the Arbitration Court with regard to wages, the cost of mining has been increased, and it is doubtful whether operations can be carried on at a profit with the present low price of metals.

DENVER, COLORADO.

Dredging at Breckenridge. — Zinc at Leadville. — Floods in the San Juan. — New Orebodies. — Battle Mountain, Nevada.

Dredging at Breckenridge is now proving an abundant success after a long record of failure. There are four dredges steadily at work. Two belong to the Colorado

Mineral Districts of Colorado.

Gold Dredging Co., a Lewisohn concern, of which H. W. Loman is manager. One of these is operating on Swan creek and the other in the valley of the Blue, just at the mouth of Swan creek. Both are Bucyrus machines, and they handle from 3000 to 4000 cu. yd. per day, and work steadily as clock work. A large area of recent alluvium or re-worked glacial material is available. The pits are 40 to 45 ft. deep. The gravel rests mainly on soft black shale, but in places lies on the intruded porphyry, and occasionally on quartzite. The ground has all been thoroughly prospected with Keystone drills and its value is said to be about 20c. per yd. On French creek, above Breckenridge, two smaller dredges are at work, both doing well.

One belongs to Ben S. Revett, and the other is known as the Reiling dredge. The latter is now working just off the mouth of Nigger gulch in unusually rich dirt. The June output, \$50,000, would figure out to nearly \$1 a yard but it is not likely that the gravel as a whole is as rich. The area has not been so well prospected as on Swan creek.

Farnacombe hill, the famous locality from which wire-gold specimens have long come, is deserted except for a few lessees. The larger output now comes from the veins of mixed sulphides. The Wellington is now shipping regularly an ore which contains 45 to 58% lead; 4 to 5% zinc, 10% excess iron, 11 oz. silver, and a small amount of gold. The Sallie Barber and the Country Boy are shipping zinc, and the Pennsylvania is sending out a little lead-silver ore. The Gold Dust concentrating mill, near the railway station, is running and shipments will soon be resumed at several other properties. It is estimated that shipments of 1000 tons per month will be made before spring.

On Chalk mountain, near Robinson, Charles J. Moore is re-opening the Pearl. This mine was a good producer of silver in the 70's, but has lain idle for many years. The vein is in the Weber grits and has a micaceous sandstone hanging wall. The old workings are badly caved and present shipments are made from the dump, a silicious product worth about \$8 per ton being sorted out.

At Leadville things are looking up a bit, and the feeling that the worst is over seems to be general. No manganese ore is being shipped and the principal output is still the silver-lead carbonate. Next to this in importance is the zinc ore and then the iron. Zinc of two grades is distinguished. One contains over 40% zinc, and is sent direct to the smelters; the American Metals Co., and the United Zinc & Chemical Co., being large buyers. This ore is reduced at the Kansas plants and the cinder, carrying what gold and silver is present, is sent back to Colorado for treatment. Lower grade ore, running about 20 to 25% zinc is treated locally in the plant of the American Zinc Extraction Co., at the mouth of the Yak tunnel, a 40% product being made for shipment, or is sent to the mill of the Empire Zinc Co., at Canyon City. The American Smelting & Refining Co. also buys mixed lead-zinc ores for treatment at their Pueblo zinc smelter. Since, however, they only manufacture zinc for their own use, with a little for the galvanizing plant of the Colorado Fuel & Iron Co., they are not aggressive buyers of zinc ores. The principal shippers from Leadville now are the Iron-Silver, Ibex, Yak, Sunday, and Wolfstone. The Iron-Silver is making steady shipments from the Tucson mine, having installed a wire tram for delivery to the railway and changed the hoist from steam to electricity.

The shipment of ore from the Hahns Peak region mentioned recently in these letters, was made by the Hahns Peak Gold M. & M. Co., and came from the Royal Flush mine. The shipment consisted of 44,924 lb., and netted \$104.80 per ton. It contained 156 oz. silver and \$1.99 gold per ton. The shipment is of some importance as representing the first considerable amount of ore sent from this area since the Denver, Northwestern & Pacific railroad was built into the region. Since, however, the ore was hand-picked and represented the accumulation from two or three seasons' work, the question of quantity available is yet to be settled. The best opinion seems to be that the veins so far opened are not likely to be important producers and that the best hope for the district is in a revival of placer mining.

The floods in the San Juan have badly damaged the railways. Telluride is entirely cut off and is now getting mail by stage. It is estimated that it will be six weeks before the Rio Grande Southern is again ready to handle ore, but that communication between Silverton and Durango will be sooner established. In the meantime the Durango smelter and a number of the mines will probably have to close. The dam of the Telluride Power company went out and Telluride was at first in darkness. Connection has been made with the lines of one of the other companies and power and light are again available.

New discoveries and rumors thereof are frequent. Salida has been excited over some \$100 ore found in an old tun-

nel near town, and a mild stampede occurred there last week. There are whispers of a find near Crested Butte and the ore-shoot found in the Nightingale at Cripple Creek is being eagerly sought on neighboring ground. Alex Walker, one of the lucky Colorado men who found the rich vein near Battle Mountain in Nevada, is home and is showing specimens of ore which is certainly rich enough to satisfy the most fastidious. The vein is said to be 3 in. thick. It is a clear white quartz bound together with wire-gold and assays thousands of dollars to the ton. The mine has been sold to A. L. Mohler, vice-president and general manager of the Union Pacific, and certain Omaha associates who are preparing to open it.

SALT LAKE, UTAH.

Utah Dividend Payers.—Grand Central Wins Suit. — Tintic Smelter Closes.— Merger of Tintic Mines. — Iron Blossom Development. —Daly-Judge.

Recently a number of mining companies operating in Utah have posted monthly and quarterly dividends. These include the Silver King Coalition Mines Co., with a dividend of 15c. per share, amounting to \$175,500; Colorado, 8c. per share, totaling \$80,000; Iron Blossom, 8c., totaling \$79,200; Sioux Con., 7c., totaling \$52,457; Uncle Sam Con., 2c., totaling \$10,000. The King is the silver-lead producer of Park City, which has paid over \$12,000,000 in dividends to date, and engineers claim that the property will eclipse this record in the next 20 years. The mine is paying at the rate of about \$1,000,000 per year. In addition to four regular dividends, an extra is posted during the holiday season. The other dividend-payers in the list are Tintic producers, having good records as profit-makers. Another mine, Utah Con., of Bingham, is scheduled for payment during the month of its quarterly dividend of \$150,000.

The long pending suit between the Grand Central and Mammoth Mining companies has finally been decided in favor of the former by the State Supreme Court. The case has been before the courts for more than ten years, and was brought by the Grand Central for the purpose of recovering the value of ores taken from their ground by the Mammoth. The Mammoth claimed apex rights, but the court awarded damages of \$91,349 and interest from the time the ore was taken out of the Grand Central ground, bringing the total to \$151,030. This judgment was awarded the Grand Central, November 11, '07, and the Mammoth company immediately appealed to the United States Supreme Court. That court held that they had no jurisdiction, and the case was remanded to the Utah court for final review. The result has been anticipated as the Grand Central has won on every issue. The interest and original award to date bring the amount up to \$175,147, and as there is no further appeal from this ruling the Mammoth company will have to pay.

Jesse Knight has announced the intention of the Tintic Smelting Co. to close the plant at Silver City as soon as the ore in the bins can be used up. This plant comprises four lead and one copper furnace of a capacity of 225 tons each. It was commissioned less than a year ago, and is said to have lost over \$200,000 in that period. Mr. Knight said they found it impossible to get the ores needed to keep the plant running, and that so far as he knew they would make no attempt to re-commission the smelter. All the ores from the Knight mines will be sent to the United States furnaces at West Jordan, 13 miles below Salt Lake. Tintic and Pioche producers, which were the principal contributors, have arranged with the United States and American smelters to treat the ores now being extracted. The smelter cost upward of a million dollars, and with the losses sustained to date, it has been an expensive affair for the Knight interests, who owned all the stock. At one time they were dickering with Cole-Ryan Syndicate for the purchase of the plant. They were offered only \$500,000 and refused to sell. A few months ago they closed the plant and made alterations. It has been running a couple of weeks, when a check-up of the stock on hand showed the heavy loss being entailed. A wire was sent to Cole-Ryan to re-open the sale, but no reply was obtained, and the de-

cision to close down was announced. With these ores the United States company will place its six lead furnaces in commission, and commence running this portion of its plant at full capacity for the first time in over two years. The supply of silver-lead ore is limited, and both the valley plants are out 'hustling' in every camp within a radius of many miles for this character of ore.

Since C. E. Loose, of Tintic, and his associates obtained control of the Carisa mine a number of people have been wondering what the new owners proposed to do with this property. The Loose crowd control the Grand Central, Victoria, Sioux Con., and Carisa, and Mr. Loose is general manager of all these. Last week he made a careful inspection of the Ajax mine in the same camp, and it has since leaked out that his people propose to get control of this property. As soon as the controlling interest in the Ajax has been transferred, all the properties, with the exception of the Sioux, are to be merged in one large company, and the old producers worked on an extensive scale. The four properties have paid over \$2,000,000 in dividends to date, but none of them have paid dividends for several years. The recent deep workings in the Grand Central,

Map of Utah.

2100 ft. deep, have resulted in opening some large deposits of marketable copper ore, and it is believed that this will be found at depth in the adjoining properties. For this reason it has been decided to incorporate them in one big concern which will have one of the largest areas of mineral-bearing ground in Tintic.

At the Iron Blossom mine they have again caught up with the high-grade ore in the south drift from the north shaft. For more than a month the management has been extracting a large tonnage of low-grade ore, and this caused the company to pass its August dividend. In the north drift of the south shaft they are running a level to connect with the workings in the extreme north end of the company's territory. This working is now in a good shipping-grade of ore, and Mr. Roundy, the manager, says that he is sure they will be able to prove the existence of the first-class product for a distance of 3000 ft. In the meantime the Knight's are having deeper work done in both the Iron Blossom and the Colorado, and are getting some encouraging results. They take the view that they are certain to get secondary enrichments, such as have been found in the Mammoth, which is mining a rich ore below the 2200-ft. level.

One of the most important finds that has been made in

Park City for several years is that in the Daly-Judge property. George W. Lambourne, manager, says they have first-class ore on what is known as the great 'back vein' in that camp. At a point a few feet from the 1400-ft. level, a winze was sent down a distance of 70 ft. This went through the fissure, which is found in the limestone and found a 'blanket' vein 'frozen' to the quartzite. Mr. Mason reports from the mine that they have not gone through the deposit yet, and that a second winze 50 ft. farther on is getting into this ore. Several years ago the management tapped the ore below this fissure at a point 500 ft. from the present find. At that time a heavy flow of water was encountered, and as no rich ore was taken from the upper portion of the zone, the work was abandoned. The find has greatly stimulated the activity of the company in carrying on development. Those who have been permitted to inspect the mine are much pleased with the ore, and the opinion is that they are now coming into a large deposit. A tunnel-site, comprising 360 acres, has been bought; contracts are being let for buildings, and the power plant is almost completed. Within 60 days the work on the tunnel, that is to be sent into the mountain from the Snake creek side of the range, will be under full headway, and during the winter months this channel will be cut through into Daly-Judge territory, and this avenue will draw off water from all the workings to a depth of 1800 ft. With the completion of this work, all of the obstacles will be removed and the company should then enter upon a career of profit-making.

CHIHUAHUA, MEXICO.

Railroad Development. — Zinc Mining. — New Smelter at Naica. — Santa Eulalia.

That Chihuahua is to have a second railroad line from El Paso is now practically assured, and it is not improbable that it may be completed before the end of 1910. The Mexico Northwestern Railway Co., of F. S. Pearson and associates, which has within the last six months acquired the Chihuahua & Pacific, the Sierra Madre & Pacific, and the Rio Grande, Sierra Madre & Pacific railroads, as well as the large timber holdings of the defunct Greene company, has two locating engineering parties in the field between Nuevas Casas Grandes, the terminus of the line south from El Paso, and Madera, the centre of the timber tract and the terminus of the line north from Chihuahua. As soon as the route has been determined, construction will be pushed, as the company is anxious to get the line completed into El Paso in order to place the timber and lumber on the El Paso and southwestern Texas markets. The length of this connecting link cannot exceed 120 miles and there is reason to hope that it may be completed before the close of the coming year. As this company is closely allied with the one owning the electric street railways of Mexico City, and the hydro-electric plant at Necaxa, Puebla, which furnishes light and power to the City of Mexico, it is readily seen that there will be no lack of funds and that it may be depended on. On the branch that will run west from Miñaca, the present terminus of the Chihuahua & Pacific railroad, and which is to eventually reach the west coast of Mexico, it is not probable that any important work will be done before some time next year. It cannot be learned whether Pearson has taken any real interest in the Ed. Hartman concession for a railroad from Chihuahua to Monclova, in the State of Coahuila, though it is recognized that such a road would be an important distributor of the Mexico Northwestern's timber products into the coalfields of Coahuila, and possibly, by other connections, into the markets of southeastern Texas.

Since the adoption of the new tariff by the United States, zinc mining in and about Chihuahua has been completely paralyzed, though Leonard Worcester, Jr., who purchases for the Vogelstein interests, is quoted as stating that he is now prepared to purchase for European connections on as favorable terms as formerly given on shipments to the States. The Calera Mining Co., generally considered as having the largest zinc-sulphide deposits in the Republic, at San Isidro, in western Chihuahua, has ceased operation, largely because of the zinc market. This company, how-

ever, because of the complexity of its ores, is dependent upon a separation of the minerals. It is using the Sutton-Steele pneumatic tables for the separation of the galena from the zinc-blende, with success, but a number of additions and alterations are needed. Advantage is to be taken of this shut-down to attend to them.

Persistent rumors have been afloat for some time past to the effect that the Compañía Minera de Naica, operating the San Pedro mines of Naica, one of the largest lead producers in Chihuahua, would build its own smelting plant at Conchos, the junction point of its railroad from Naica with the main line of the Mexican Central, and now the statement is positively made that the company will spend \$1,000,000 in the erection of a 600-ton smelting plant. Its mines have enough ore to supply such a plant for 25 years, and by going into the market for custom ores could continue for a longer period. Others assert that the Naica company has no definite intention of building a smelting plant.

At Santa Eulalia, the Cocineros and Concepción have been taken over by the Inglaterra Mining Co., of New York, with a capital of \$50,000. Bainbridge Colby is at the head of the enterprise. Development will be immediately started. The aerial tram to connect the Mina Vieja of the American Smelting & Refining Co. with the town of Santa Eulalia will be completed and in operation by October 1, and a branch will be immediately started to run to the Sin Nombre mine, a mile distant.

MEXICO.

Flood Situation. — Fuel-Oil for Railroads. — La Noria, Zacatecas. — San Juan, Taviche. — San Francisco del Oro Ore-Tests — Cinco Minas.

Usually the first accounts given by the daily press of any great disaster can be discounted severely, but in the case of the terrible floods in northeastern Mexico the reverse has unfortunately been true. As news slowly filters in from the stricken district, the death-roll steadily increases, and the damage, not only to town property, but to vast tracts of rich agricultural lands along the river banks has been very great. E. N. Brown, the president of the National Railroads states that in the whole 23 years of his Mexican experience he has never seen anything approaching the damage from the recent floods. The damage to the steel plant at Monterey may affect the railroads and cause further delay as the National had just made a large contract for steel rails, and it is a problematical question as to how soon the steel plant will be able to fill the order.

The shortage of fuel-oil for the supply of the locomotives on the Mexico Central is at an end, and the coal-burning locomotives which had been fixed up and pressed into service, are again being put out of commission. The cause of the shortage is a mystery, as the Ebano oilfields are producing abundantly, and as already reported, a pipe-line is being built from Ebano to Tampico, so that oil can be piped to the Waters Pierce refinery. Also the new gas-plant that is being built for Mexico City is to be supplied with crude oil for gas-making from the same source. Oil is supplied to the railroad under contract for one peso per barrel, and as other and more profitable sales can be made, it is rumored that the company would be glad to see its contract with the Central terminate; but as the operating expenses of the Mexican Central have been greatly reduced by the use of fuel-oil, it is not to be expected that they will allow the oil magnates to slip off so easily. It would seem that dealing in oil has somewhat the same effect on human nature as dealing in horse-flesh.

The La Noria Development Co., which owns the old Noria mine, near Sombrerete in the State of Zacatecas, has been pushing development for a long time. The orebody, which was struck on June 8, has been thoroughly explored, and a mass of ore assaying two metres wide has been opened, assaying an average of 8 kg. silver per ton. It is stated that they now have upward of 60,000 tons of ore blocked in the lower levels, that will net \$10 per ton after allowing for estimated costs of mining and milling. The company intends erecting a large mill for treating the ore by concentration and cyanidation. Reports have come from

the Asientos district of Aguascalientes that good copper-silver prospects have been discovered, and quite a rush has resulted to take up claims.

The San Juan mine, at Taviche, in the State of Oaxaca, has been a good producer for the last eight years, but has been in litigation for two years, the contestants being Juan Baights and C. A. Hamilton. The right of possession was finally decided by the courts in favor of Juan Baights, who placed the property on the market with the result that Denny Bros., acting as representatives of an English company, now hold the mines under bond and G. A. Denny is making a personal examination of the mine with a view to complete the purchase. A group of important mines in the State of Zacatecas have been taken under option by George A. Wadill and associates. The mines comprise the Asturiana in the Veta Grande district, owned by the Negociación Minera Anónima Asturiana y Anexas, the Los Compos mines, and the Carmen reduction plant, adjoining the Los Compos, making a total of over 100 pertenencias. Mr. Wadill has recently been at the properties in company with Victor M. Braschi and C. F. Rhodes, who were acting in an advisory capacity. The option granted by the owners allows a period of eight months in which to un-water, examine, and sample the mines. It is announced that the work will begin without delay.

At Parral, in Chihuahua, a large force is working on the new mill of the Parral Consolidated Mining Co. The San Francisco del Oro mines at Parral are making a shipment of 500 tons of ore to Wales, England, for the purpose of making a thorough series of working tests, with a view to finding a solution for the treatment of the rebellious ores of this mine, of which a large body is blocked out. A. H. Kennedy, a well known contractor and millwright, was at Parral recently on his way to erect a 100-ton cyanide plant. Nearly \$20,000 worth of machinery for the development of the Cinco Minas has been shipped into the mine, at Hostipaquillo, State of Jalisco. The machinery includes an air-compressor plant, drills, pumps, and electric motors, it will be erected as soon as possible, and then development can be rapidly pushed. The Mina Grande, in the same district, which was recently purchased by Luis Chevrillon, was taken over in the interests of Francisco J. Tournier, the well known and wealthy French engineer, who is the principal shareholder in the Dos Estrellas mines in the Tlalpujaha district of Michoacan. A company has been organized with a capital of \$300,000 to develop the mines and Mr. Fournier has taken a large block of the stock. The fact that Mr. Fournier is behind this means much for the district. Three of the adjoining properties have also been bought in by the same interests. Operations will be in charge of Mr. Hoeling.

BRITISH COLUMBIA.

Le Roi Increasing Work. — Phoenix District. — B. C. Copper Shipments. — Granby. — Tip Top Bonded. — Zinc at Arrow Lake. — Lucky Jim.

The working force at the Le Roi mine has been increased to about 80 men, and in addition to the three diamond-drills, a few machine-drills have been put into commission. A body of good ore has been opened up on the 700-ft. level, and some stoping is being done on the 600-ft. The development of the lower levels of the Le Roi will be energetically extended from this time forth, and all of those interested are sanguine that good results will ensue. The Consolidated group and the Le Roi No. 2, Ltd., made the usual shipments for the week, making the total tonnage shipped from the camp for the week ending September 4, 4370 tons of ore. The smaller properties about this camp are not as active just now as formerly. Work has been stopped at the Evening Star, owing to legal difficulties with one of the lessees. At the Hattie Brown but little development is going on at present, but the management states that some diamond-drill work is about to be undertaken. In Blue Bird affairs there has been a lull, while the company, which has just bought out the lessees, draws up its plans of operation and work. The outlook for the camp, however, is better than for some time. The main reason why some of the more meritorious smaller properties are not

working is the owners will not lease to men who have no capital with which to work properly. There are many applicants, but they have not got the money necessary for the systematic working of the Rossland low-grade mines. The Phoenix district received a visit from J. A. Lewishon, director, and J. Parke Channing, consulting engineer, of the New Dominion Copper Co. during the past week. In company with J. E. McAllister, manager for the B. C. Copper Co., and J. Seward, manager of the Dominion property, they visited the Brooklyn and Rawhide (Dominion) mines at Phoenix; the Mother Lode (B. C. Copper) at Greenwood, and the Sunset and Idaho (Dominion). It is generally understood that Mr. Lewishon is deeply interested in both the B. C. Copper and Dominion Copper companies. The B. C. Copper Co. is making regular shipments of nearly 8000 tons per week and the activity of the company is felt all through the district. The company has a small force of men working on the Sappho group, near Midway. They have also applied for a water-right in the Similkameen water district, to be used in connection with the Wellington mines. It is said that the directors of this company have planned to declare dividends when the surplus shall have reached the sum of \$200,000. The B. C. Copper Co. has been negotiating for the last few days toward the acquirement of a group of claims near Kamloops, on which there is a promising showing of iron ore. The 'glory hole' work at the Mother Lode mine is to be carried on more extensively in the future. This class of work cuts down the working costs, and enables Boundary mines to produce $8\frac{1}{2}$ c. copper. Work is soon to begin on the Canadian Pacific railway spur to the Phoenix Amalgamated group. As soon as this is completed the Consolidated M. & S. Co., of Canada, will begin ore-shipments from the property to its Trill smelter. This concern will also ship from the No. 7 mine in Central camp as soon as the proposed spur is finished. There are now 14 men on development at the No. 7. It may be necessary and economical to build a concentrator to reduce the ore from the No. 7 mine. The general manager for the Granby Con. M. S. & P. Co., A. B. W. Hodges, left during the past week for a trip of inspection to the Queen Charlotte islands. R. P. Williams, a local mining man, accompanied Mr. Hodges, being associated with him in the Contact group, at Tasso harbor. The Granby company will soon finish the work of enlarging its eight furnaces and will be in a good position to reap the benefit of the expected rise in the price of copper. Recent improvements have cost the Granby about \$250,000. In addition to enlarging the furnaces, the blowing-plant has been augmented, also the converter-plant and one or two of the old wooden buildings have been replaced by steel structures. It is thought that under the improved working conditions the Granby can place blister copper in New York at $8\frac{1}{2}$ c. per lb. This concern has already paid \$5,000,000 in dividends on an issued capitalization of \$13,000,000. It is now eight months since the company paid its last dividend. Among the large shareholders are J. J. Hill, First National Bank, of New York, American Metal, Nichols Copper, and H. L. Higginson, of New York. The Tip Top and Bay mines are reported as bonded to W. H. Sherrod, of Seattle, and associates. The California and Alpha, in Wellington camp, are under consideration by the same people. The Riverside claim has been bonded to John H. Arnold, of Columbus, Ohio, for a figure close to \$16,000. It is stipulated in the bond that a concentrating plant must be erected within four months; the payments to extend over two years. Some 90 tons of good ore have already been shipped from this claim as a sample.

At Nelson the Big Ledge zinc property on the Arrow lakes, has been taken on option by W. J. Greenstreet, of the Guggenheims. The Big Ledge has a prodigious showing of black-jack, assaying as high as 40% zinc. Very little development work has been done, but it is said the price of the option was near \$400,000. The Lucky Jim mine is making occasional shipments of zinc-blende, assaying approximately 52% of the metal. There is also about 16,000 tons of concentrating ore knocked down in the mine, and it is said that plans are under way for the erection of a concentrating plant.

FAIRBANKS, ALASKA.

Bonnefield District.—Rich Veins.—Duration of Placer Mining.—Gold Stream.—Hot Springs District.—Koyukuk.

The Bonnefield district, 80 miles south of Fairbanks, is attracting prospectors, and many locations have been made of placer and lode claims. Clarence Berry and James H. Hamil and their associates have taken up claims in that district including creek-beds and bench-grounds. The locality is not far from the Government road that is being constructed between Valdez and Fairbanks, and is situated in the northern foothills of the Alaskan range of mountains. One of the most promising prospects is the Jerome lode, in control of The McConnell, Chute & Crawford Mining Co., of Fairbanks. This lode is 250 ft. wide, intersected by Chute creek, whereby the formation is exposed. The lode is composed of mineralized quartz and porphyry, and is enclosed by schist and porphyry; but has a thin limestone capping. An average of 100 assays is said to have shown \$18 per ton in gold. An Allis-Chalmers prospecting mill was hauled in and erected on the property this season and operated 37 days on the Jerome lode ore, crushing 1000 lb. in 10 hr., from which was recovered \$5 per ton by amalgamation, and a high-grade concentrate.

Other lode prospects are being developed nearer Fairbanks. Among these is the Pioneer group on Chatham creek, a tributary of Cleary, where Bob Fleming, in 1906, dug a prospect hole to bedrock and took out \$103,000. In doing this work plenty of quartz was uncovered, and in 1908 W. S. Reese, T. L. Thurston, R. R. Myers, and R. C. Erchinger, who had made quartz locations, began work and opened a well defined vein $3\frac{1}{2}$ ft. wide, containing gold-bearing ore, samples of which assayed \$50 per ton according to large tests made in the Brumbach, Hamilton & Kellogg mill at Fairbanks. A 75-ft. shaft has been sunk, and a 500-ft. tunnel driven. Money is being raised for work on a larger scale next season. An extension of this lode, called the Jupiter, is owned by John Dahl, W. Larson, James Wickersham, Jas. W. Hill, J. L. Sale, L. S. Robe, T. L. Thurston, and others. Enough work has been done to show an 8-ft. vein with ore assaying \$20 per ton. The Free-Gold lode, on Bedrock creek, a tributary of Cleary, six miles from Chatanika, has a 50-ft. shaft, and a 70-ft. drift on the vein from 1 to $2\frac{1}{2}$ ft. wide. This belongs to W. C. Hall and L. B. Rhoads.

On the creeks north and northwest of Fairbanks there are 104 plants in operation on placer-ground; a plant usually consists of steam-thawing and steam-hoisting equipment, and a pumping station for delivering water to the sluices and for keeping the bedrock workings clear of water. Besides there are a good number of properties working by windlass. The force of men engaged on all these properties is estimated at 2500 to 3000. Operations have been handicapped by a shortage of water, though heavy July rains perceptibly replenished the supply in the reservoirs and ditches. While bedrock driving, hoisting, and sluicing will continue for years, the consensus of opinion is that the richer channels are pretty well worked out, and this season will practically finish the ground embodied in many of the leases, or 'lays' on Goldstream, Dome, Esther, and Cleary creeks. There are some lessees, however, having grounds that will last through one or two more seasons. Some of the creeks more recently opened are just now at the zenith of their production, but they are comparatively small in area. In general the mica-schist bedrock and auriferous stratum of gravel overlying it are from 60 to 200 ft. below the surface on the streams in this district. On Goldstream the bedrock shafts are from 60 to 125 ft. deep, while those on Dome creek reach a depth of 150 to 200. Below are given some data which may be considered typical of the operations in the district. The 83-acre tract at No. 17 Goldstream belongs to L. L. James & Co., of California. It is being operated by the Union Mining Co., composed of George La Montagne, Joseph and Mike Susang, and John Kucel, who began as lessees in 1908 and expect to continue till the bedrock area is worked out. In this case the depth to bedrock is 60 ft., and they are operating through three shafts, using the trolley-lift and steam-hoist for delivering the pay-dirt to the hopper that

opens into the sluice-way. In driving and hoisting they take up 4 ft. of bedrock and 4 ft. of the gravel lying next to it. An area 1400 ft. long and 500 ft. wide has been prospected and blocked out, and on this the production progresses, handling 700 sq. ft. of bedrock per day, the value of which is estimated at \$3.25 per square foot. With a force of 65 to 75 men they hoist 700 buckets of pay-dirt per day, there being five wheelbarrow loads to each bucket. A clean-up is made every Wednesday. One clean-up which I saw yielded about \$12,000; the one made the previous week exceeded \$20,000. Mr. James constantly supervises the operations, and has one or two more prosperous seasons ahead. Adjoining the grounds of the Union M. Co. is the lease of Jorgensen & Nelson, also from Mr. James. These men operate through one shaft and make clean-ups that indicate that they are in ground of the same value as that of the Union. No. 14 Goldstream, second and third tiers, belongs to Chas. Knell, and is leased to Maddock, Monkman, Kellett & Brown, whose term expires this season. In the depth of 113 ft. from surface to bedrock they sank through 94 to 96 ft. of muck and 18 ft. of gravel. While they have three plants for thawing and hoisting, only one is in operation this season, as they have not had sufficient water for sluicing. Large dumps of pay-dirt have been hoisted, which will be sluiced after the lease expires. It is claimed that this dirt contains gold to the value of \$1.50 to \$1.75 per square foot. Quarley & Ness are operating on Vogelín & Aubert ground, Goldstream, and have done driving from four shafts,

for another season. Their method is to block out the ground in squares of 200 ft., then thaw and drift. The general average of the value of the material is \$1.75 per sq. ft. of bedrock. Ed. Thomas & Co. operate the Blue Bird fraction, and some adjoining ground. They have two shafts and a good deal of ground blocked. Besides, they have been sluicing their winter dump, the largest in the Tanana valley. The gross clean-up from this dump was \$140,000. It came from 65,000 sq. ft. of bedrock. Work will progress here this winter in driving on the bedrock, hoisting it to the dump for sluicing in 1910.

George Friend, an owner of ground at No. 4 Below, on Dome creek, has had a good season's work. His partner is Frank Lawson. It is claimed their work has almost reached the finish. The winter work on all these creeks, consisting of thawing the bedrock stratum, and hoisting the pay-dirt to the dump for summer sluicing, is important, because then it can be washed rapidly at a time when water is most plentiful. In these notes there is no attempt to fully cover the field, but the operations and conditions herein outlined are typical of what would be found on Esther, Cleary, Engineer, and Chatanika creeks.

The question of operating dredges in this district has not received much attention. The great depth of the pay-strata is a serious obstacle. It is believed that there are benches, however, that might be considered dredgeable. The Hot Springs district has been active, excepting that there was a period in mid-summer when the water-supply gave out.

Mining at Fairbanks, Alaska.

and are handling a good yardage of gravel.

M. A. Mahoney and Chas. McDonald have put in their first season of a three years lease on one claim of the Vogelín & Aubert ground, at No. 16 Goldstream. They have three shafts and are driving from two of them. They are lifting 2300 wheelbarrow loads of gravel per day, taking it to a depth of 8 ft., the value of which is said to be \$3 per sq. ft. of bedrock. There is no shortage of water here, and a steam scraper is used for moving the gravel from the dump into the sluices. The sluicing season will close about October 8. Dave Yarnell has done well on Dome creek, where he has nearly worked out the ground on No. 1, and the upper half of No. 2 Below. He has operated from four shafts, and is sluicing a large dump on the lower half of No. 1. The depth to bedrock here is 150 ft., the barren overburden being 80 ft. thick. The principal pay comes from the lower 7 ft. of the gravel and a foot or two of the mica-schist bedrock. This group is well up the creek, and from here down-stream to the Chatanika is a string of hoisting, thawing, and pumping plants for a distance of eight miles. Much of the ground here belongs to Cook & Co., and Barnette & Co., of Fairbanks, all of which has been and is now operated under lease. Riley & Atwell are working half a claim, with two shafts, but will finish this season. Their pay-channel extended along the course of the creek, and had a width of 150 to 230 feet. It was opened by shafts 150 to 160 ft. deep. King & Manson, lessees of the upper end of No. 5 Below, have mined the pay-channel 400 ft. long, and 150 ft. wide, through one shaft. The pay-dirt was 3 ft. thick, and yielded \$2 per sq. ft. of bedrock. They finish up their leased ground this season. C. J. Robinson and associates own and operate the third tier, No. 6 Below, Dome creek, having two 210-ft. shafts. The pay-stratum is 4½ ft. deep, and was 200 ft. wide and 1102 ft. long. They have operated two seasons, and have unworked ground enough

This was partly overcome by heavy rains in the later days of July.

Fairbanks is a homelike place as well as an important supply-centre for a great area which is being prospected. By this time next year the Government wagon-road from Valdez to Fairbanks will be finished, and this will permit of wagon and automobile travel between those two points in summer; the travel in sleds, drawn by horses, is extensive now during the winter season.

The Innoko river, which joins the Yukon near Holy Cross Mission, rises in the Alaskan range, close to the headwaters of the Koskukwim, and has been much explored this season. The principal placer-mining points on the Innoko are Gaines, Little, Ophir, and Yankee creeks, which come into the main stream from 500 to 525 miles above its mouth. The trading places are Tihkakak, Gierder, and Simel. The output of the Innoko this season is estimated at \$270,000.

A. Pelky and F. G. Kimball have come out of the Innoko after a stay of three years on Gaines and other creeks. They brought gold nuggets of the value of \$1200; one nugget weighed over 25 ounces. They report that the greatest hindrance to operating on the Innoko is the scarcity and high price of food and mining supplies. Operations on the Koyukuk are at Bettles, which is at the head of navigation, and at Coldfoot, 75 miles up-stream from Bettles. The most productive camp is at Nolan, or Wiseman, 18 miles above Coldfoot. It is reported by a resident of that country that the 1909 output of placer-gold will amount to \$500,000. The best workings are on Nolan creek, where the discovery was made in May, 1908. Among the operators are Johnson & James, on No. 5; Murray & Nolan, on No. 2; Nolan & Calhoun, on No. 4; Olson & Anderson on same creek. Work closes for the season about September 15. Provisions are reported to be available in plentiful supply at Bettles, and freight rates were reduced some this year.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Copperas is obtained almost wholly as a by-product in acid-cleaning of iron and steel sheet and wire. Thus the bulk of the output comes from the United States Steel Corporation. The amount produced in 1908 was 35,334 tons, worth \$388,674.

Angle of slope at which walking, as distinguished from climbing, on hill sides ceases to be possible is about 38 degrees from the horizontal, or a rise of 1 ft. in 1.61 horizontal. On a slope of 1 in 1 (45°) it is quite impossible to move without the aid of the hands.

Application for patent does not relieve the owner of a claim from the necessity of doing assessment work within the same year, unless the proceedings advance to the point where the money required is paid over to the local Land Office within said calendar year. It takes a number of months to secure patent, even when no opposition is made, and it is unsafe to rely upon exemption from assessment work being acquired in that manner.

Vanadium ores are sold on the basis of the contained vanadic oxide. The lowest quantity which will be accepted is 15% V_2O_5 . The price is approximately 50c. per pound of the V_2O_5 in the ore. Vanadium ores are usually capable of concentration, though with some varieties the slime-losses are heavy. The principal ore is vanadinite, a chloro-vanadate of lead, having 19.4% V_2O_5 when pure. Its specific gravity is 6.66 to 7.23; hardness 3; resinous lustre; white to pale yellow streak; opaque to translucent; and deep red, yellow, or brown in color.

Chromite requires fusion with certain mixtures to render the chromium soluble. A good method is fusion with 10 parts of bisulphate of potash, or with a mixture of 5 parts each of bisulphate of potash and potassium fluoride, or with 5 parts of hydric potassic fluoride alone. The fused mixture is soluble in acids. The fusion is made in a platinum crucible and requires a high temperature and prolonged heating. Undecomposed particles require re-fusion. Fusion with 5 parts of caustic soda and 3 of magnesia converts the chromium into salts soluble in water; and fusion with 12 parts of caustic soda will yield the same result.

Strength required for neat cement, according to the standards of the American Society for Testing Materials, is as follows:

| | Lb. per sq in. |
|---|----------------|
| 24 hr. in moist air..... | 50 to 100 |
| 7 days (1 day in moist air, 6 days in water)... | 100 to 200 |
| 28 days (1 day in moist air, 27 days in water) .. | 200 to 300 |

These are minimum strengths. It is apt to be the case that a cement which develops an excessive strength within 28 days will not hold its own as well as a brand which shows a more gradual increase. The best cements show a strength of about 600 lb. per square inch in 28 days.

Check-drilling of a placer-property need not be as close as the original drill-sampling if the purpose be merely to establish the probability of error. The sufficiency of drilling only a few holes over a previously tested area would depend entirely upon the object in view, and the reputation of the original sampler. If the intent be to check the work as a preliminary to purchase it is usual to thoroughly re-sample the ground, notwithstanding the reputation of the first sampler. A few drill-holes judiciously placed over an area which had been well-tested would be enough to prove the probable accuracy or error of the work.

Assaying antimonial gold ores is best done in a crucible, using a small amount of nitre for oxidizing the sulphide. Some assayers regard it as important to estimate the amount of nitre needed for complete oxidation in order to insure the best results. The assay charge should contain a considerable proportion of borax. A method used by C. O. Bannister consists in charging the ore with sufficient nitre to render oxidation complete, into a hot crucible, a little at a time, and before it melts, to scrape it out into an iron mortar and mix with red lead, charcoal, and fluxes. This procedure eliminates to a considerable extent the need of cleaning the slags when assaying low-grade ores. The slags, however, should always be tested, and may require re-treating.

Pitchblende is in steady demand, as a material for the preparation of radium chloride and bromide. It is a black granular mineral, sometimes botryoidal, and resembling pitch, though sometimes blotched with brownish or yellowish spots. Its specific gravity is 5 to 9.7, and its hardness 5.5; streak on porcelain gray, olive-green and dark brown; exceedingly brittle. The most characteristic test is with the borax bead, which is green, becoming enamel-black on flaming. It is soluble in nitric acid to a yellow solution, from which a bright yellow precipitate is thrown down with ammonia. As pitchblende (uraninite) is a uranate of uranyl and lead, with other metals, it generally yields reactions for lead. It occurs in granitic rocks, and in metallic veins, often with sulphides of silver, lead, cobalt, nickel, iron, zinc, and copper.

Suction gas-producers are those in which the air and steam are drawn through the fuel-bed by means of the exhausting action of the gas-engine piston. These producers may have the vaporizer connected therewith as an integral part of it, or it may be separate, or even heated by the engine exhaust. The regulation of the steam delivered into the producer is of great importance, especially where the load on the engine is variable, otherwise the quality of the gas will vary, or the fire in the producer will be extinguished. The possibility of automatically controlling this is one of the chief advantages of the suction type. Pressure-producers do not yield a gas of uniform composition, and this occasions difficulty in exploding in the engine-cylinder. The leading models of suction-producers are the Nagel, Otto, Fairbanks-Morse, Pintsch, American, Crossley, Smith, Baltimore, and Wyer.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Prospects at Zacatecas.

The Editor:

Sir—Zacatecas is one of Mexico's most noted 'antiguas', the mines having been discovered about 1540, and the production since being exceeded in value only by that of Guanajuato, but whereas the latter is almost entirely a silver-producing camp, the Zacatecas ores contain often a notable proportion of gold, and yet there are comparatively few new enterprises on foot. Meanwhile at Guanajuato a veritable boom has developed during the past five years. Probably the proximity of the latter to the City of Mexico has something to do with it. Mexican civilization patterns largely after that of Europe

Zacatecas, Mexico.

in this respect, that the rich steadily gravitate to the national capital, which also becomes thereby the commercial capital, leaving their properties (mines or ranches), that have made them wealthy, in the hands of local agents. If these properties be mines, they are generally ruined in the course of a few decades. This is the history of nearly all the great bonanzas of Mexico. Consequently foreign investors and promoters, looking for properties, come to the capital first to become acquainted with the owners, and are more readily attracted by districts nearby than by those at a greater distance. Hence the revival of Pachuca, Taviche, Guanajuato, Taxco, and numerous other districts in the southern States of the Republic.

It is safe to say that if Zacatecas were in any one of the Western States of the American Union, where the national mining law is in force, there would be at least five hundred new shafts going down in its hills, and a thousand prospectors digging holes over its surface, but being where it is, and under conditions which do not recognize the prospector as a part of the game, the case is different. Only one new shaft is sinking in the district, and not a single prospector is in evidence. Thus the main glory of

Zacatecas today is in its past. With payable ore at a score of places already well known, with the finest of climates all the year round, with abundance of cheap, good labor, direct railroad connection with the rest of the world, and all the modern conveniences that the latter brings in its train, 'old Zac' is still a dull, slow place, haunted perhaps by the spirits of the thousands of aborigines who were worked in the mines as slaves till they died, in the days of the Spanish conquerors, and probably also by the ghosts of the slave-drivers themselves.

How to change this, and get the brisk and optimistic American mining operator into the field, is the problem that is agitating its citizens, and the owners of its idle mines, most of whom reside in the City of Mexico, distant less than 450 miles, or 16 hours of travel-time. There is no use for the real prospector to come here with the idea of locating some of the good ground that is open for denouncement, for he has not the money to maintain his title while a buyer is being found. And the prospector who has money is not the kind to wander around on the hills with a

pick and shovel, and dig holes on promising outcrops. It will avail nothing to re-tell the marvelous history of the district. That has been done already a score of times, until the additions and embellishments, that invariably collect like barnacles around the story, are bigger than the facts themselves. The yarn thus becomes so imposing as to alarm even a tenderfoot. Nothing is to be gained by stating the details of work in progress, for there have been but two new operators within the past four years. The 'old stagers', like the Bote, Australia, Magistral, Zaragoza, Fortuna, that have been steadily in

operation for a dozen years or more, are doing nicely as usual, and expect to continue. It remains only to write generally, and trust that Providence will cause the screed to come under the eyes of some of those who are looking for a really good thing in the way of a mining proposition. For such, the locality and the conditions are exceptionally attractive. The altitude is 8500 ft. resulting, in this latitude (about 23 degrees north), in a climate that is never hot and never cold. The town is clean and healthy, with about 20,000 inhabitants, directly on the main line of the railroad, well-lighted with electricity, supplied with a good hotel, and the mines are so close by that many are even within the city limits. All are within a radius of six miles. Good wagon roads and bridle paths are everywhere. There is an abundance of cheap labor, good for its class; excellent stocks of merchandise in the stores; unusually good meat, vegetable, and fruit markets, and a government military post, so that life and property rights are amply protected.

As for the mines, there is abundance of low-grade silicious ore, carrying both precious metals, well adapted for the cyanide process; also medium and high-grade sulphides of iron, copper, lead, and zinc,

some of which may be cheaply hand-dressed to a marketable product, while the balance is readily amenable to concentration. There is a sampling works in town, where mineral can be turned into cash in three or four days. At only a few of the mines, and in but one part of the district, has there been any serious trouble with water, though a number are down to the 1000-ft. level, and even there it is child's play compared, for instance, with such districts as Leadville or Virginia City. The lodes are large, well mineralized, and give evidence of great permanence in depth. But an insignificant fraction of their length has been explored, only, in fact, where rich mineral cropped out at the surface, and forcibly drew the attention of the early explorers.

The rich ore occurs in *clavos* or lenses, most of which have been of comparatively small size (50 to 100 ft. long and about the same high), and two to six feet in thickness, but many have been found of much greater dimensions, that have yielded millions. They follow each other in shoots or 'flocks' between the walls of the veins, and are generally connected by stringers or leaders. Occasionally there is faulting, but rarely to the extent of more than a few feet. The lower grade and concentratable material generally occurs as the envelope of these rich *clavos*. Most of the precious metal is with the iron sulphide, though the lead and copper sulphide is also payable. The zinc sulphide is usually poor in gold and silver. There is quite a little zinc carbonate and silicate in certain parts of the district. To sum up, this is a good place to come to if one is looking for an opening in mining, free from most of the inconveniences and discomforts that are usually met with in mining districts.

Zacatecas, Mexico, September 2.

Slime Concentration.

The Editor:

Sir—In your issue of August 7 I note an article on slime concentration. If your correspondent 'C', or in fact any other interested person, will come to Denver he will be shown a simple device which, in the opinion of many eminent metallurgical authorities, has satisfactorily solved the vexed question of slime-recovery. Henry E. Wood, of Denver, has in operation on a small scale as well as on a commercial basis, an apparatus which on a wide range of sulphide ores has made an average recovery of 80 to 90%, and frequently higher. Over 300 trial tests of different ores have been made, and the extraction in most cases has reached the above figures. After removing the slime the remainder of the ore passes in a classified condition to either tables or jigs of standard type. By this combination plan practically all use for vanners or slime-tables is done away with. The process is simple, requiring no extra power, and the cost of additional equipment is slight. A vacuum is not used. A minimum amount of water is required, and specific gravity enters only into the final separation of the coarsest particles of mineral and gangue. Full details on this very interesting subject will be shortly published. In the meantime, Mr. Wood is testing difficult ores sent to him. The method has been highly endorsed as practical by R. H. Richards,

of Boston, A. R. Wilfley, inventor of the Wilfley table, and many prominent mining men, engineers and metallurgists generally. It works as well on 4 to 6 mesh as on 40 mesh and finer, recovering nearly all the sulphides in the slime that are liberated at the same mesh at which the ore is ground.

WILBUR A. HENDRYX.

Denver, Colorado, August 24.

All Sliming.

The Editor:

Sir—I wish to express my appreciation of E. M. Hamilton's article on 'All-Sliming', in the MINING AND SCIENTIFIC PRESS of August 21. It would seem impossible to state the conditions obtaining in this important metallurgical method more fairly or more concisely. Few metallurgists have escaped the trials incident to some of the so-called slime-plants. I recently left, without regret, a plant in which they were attempting to agitate with paddles, pump through 4-in. pipes, and eventually cake on a suction-filter, a product of which over 20% was coarser than No. 150 mesh. In another plant of unhappy memory, while only 10 to 15% of the product was coarser than No. 200, the material was of such a nature that if an agitator stopped for 10 minutes, it never started again until dug out. In respect to many such plants, it is certainly easy to agree with Mr. Hamilton that a separation of the two products, with the normal treatment demanded by each, would yield equally good results metallurgically, with less wear and tear, and more peace of mind.

Mr. Hamilton's ideas on the collection of slime-free fine-sand are of great interest. At Flores, Guanajuato, some years ago, we noticed that the charge in our sand-collector, fed by a Butters distributor, with the usual arrangement of pipes, naturally rose faster in the middle than at the periphery of the tank. The slime had an apparent tendency to settle and slide toward the sides of the collector, often making a product that gave trouble both on the belt and in the treatment-vat. I had never seen a distributor arranged to discharge only at the sides of a vat, but it occurred to me that by so doing it might be possible to obtain a peripheral ring of clean sand leaving the slime, some of which would unavoidably settle to contaminate a more restricted area in the centre. Although we were settling in water, and continued to use our peripheral overflow, this proved to be the case, and we had less trouble with our sand in the future. In the new plant of the Virginia & Mexico Mine & Smelter Corporation, recently started at Hostotipaquillo, Jalisco, I urged a similar arrangement of the distributor, and a central weir overflow. The advantages described by Mr. Hamilton are so manifest, that I shall be surprised if others are not using the same device, supposing, as did Mr. Hamilton and myself, that the idea was original.

In regard to our control weir overflow, it had been arranged to use the Blaisdell plugs. The manager, Mr. Scobey, suggested that the plug itself might be used as a weir. This was done by simply drilling rows of inch holes around the drum, spaced vertically 4 in. apart. These rows of holes are plugged in

succession, as the sand rises, and the device works perfectly. The sand on screening shows as follows: coarser than 100, 20%; between 100 and 200, 45%; finer than 200, 35%. It contains, however, very little coagulable slime, and leaches with exceptional readiness, both in the collector and in the treatment-vat.

A feature of this plant, which is supposed to be original, and which is giving remarkably satisfactory results, is the use of Wilfley tables for separators. By sending the sand-free slime from the head of the table, directly to the slime plant, and the sand with the small amount of remaining slime to the tube-mills, the use of cones and drag-classifiers is avoided, and apparently just as good a classification and tube-mill feed is obtained. There is positively nothing to clog or break, and the process is 'fool-proof'.

Tables have been used frequently as an aid in classification. I should be extremely interested to know if they have ever been used before in a plant, to the exclusion of other classifying devices.

P. R. WHITMAN.

Jalisco, Mexico, August 30.

[It would be interesting to ascertain when the Wilfley table was first applied as a classifier in conjunction with concentration. That system was being used at the Exposed Treasure mill, Mojave, California, as early as 1902.—EDITOR].

The Editor:

Sir—In your issue of August 21 I notice an article on 'All Sliming', by E. M. Hamilton, in which he criticises the practice of fine grinding as followed at many modern mills which are treating silver sulphide ores. Mr. Hamilton criticises the use of the term 'all-sliming' in mills when after re-grinding a screen-test shows from 15 to 20% of sand which is coarser than No. 200 mesh laboratory-screen. Technically, Mr. Hamilton is correct. It is not 'all-sliming'. As a matter of practice, however, the term 'all-sliming' is generally used to describe a degree of re-grinding when leaching becomes impracticable, in other words, where the resulting material is treated as slime. In many cases a considerable proportion of the material is still very fine sand, coarser than No. 200 mesh screen, but the proportion of impalpable slime is so great that slime-treatment is advisable. Mr. Hamilton cites the cases of two companies operating mills on the all-sliming system, where the sand coarser than No. 200 mesh amounts to 15 to 20%, and another case where the proportion was even higher. He justly remarks that such work is not sliming. He further remarks that this is bad metallurgical practice. This assertion seems open to dispute. It all depends on the ore. I know of cases where excellent results are being achieved from the treatment of slime containing from 15 to 20% fine sand, coarser than No. 200 mesh.

Take for example a silicious ore in which the metal is present in the form of rich silver sulphides, often minutely disseminated through the quartz. Such is a typical Tonopah ore. Here fine grinding is necessary in order to liberate the extremely fine particles of mineral from the gangue, and incident-

ally, to allow the cyanide solution to come into intimate contact with the particles of ore. Experiments show conclusively that extremely fine grinding is essential if these results are to be attained. The economical limit of reduction is fixed by two things: first, the difficulty of concentrating the very finely divided particles of mineral, and, second, the cost of re-grinding.

It has been conclusively proved that it is impossible to cyanide such an ore successfully until the greater part of the sulphide minerals have been eliminated. Further, that it is impracticable to reduce all the material issuing from tube-mills to a certain degree of fineness at one operation. As stated by Mr. Hamilton, the cost of re-grinding the 15 or 20% remaining, would be excessive.

Although it is impracticable to re-grind this small proportion of sand until it is reduced to a slime, it by no means follows that it would pay to classify and treat it separately. The additional cost of installation and operation of a small leaching plant would more than offset any possible increase in extraction. But there are other important reasons for not separating the small proportion of fine sand. Of these the most important is the effect during filtering. In filters of the submerged vacuum type, or even of the self-contained type, the permeability of the cake is increased enormously by a small quantity of fine sand, provided that the pulp is in a state of suspension while the slime-cake is being formed. During the experimental stage, before the Goldfield Consolidated mill was designed, a series of exhaustive tests were made along the lines advocated by Mr. Hamilton, namely, moderate re-grinding and subsequent segregation into sand and clean slime. This plan of treatment was only abandoned after it was found that the clean slime formed an absolutely impervious cake on the filter, from which it was impossible to displace the gold-bearing solution.

EDGAR A. COLLINS.

Tonopah, Nevada, September 3.

Silver, and its price, is attracting much attention in the Far East. According to *In Tinland*, when Lord Morley was asked last February what would be done if the value of silver rose above 43d. per ounce, that is, to a point at which the rupee would be of more value in the melting pot than as a current coin, the answer from the Secretary of State was prompt and decisive: "We shall be quite ready to cross the bridge when we come to it. Nothing would, as a matter of fact, suit India better than a rise in silver. If it went to the intrinsic value of the rupee (43d. per ounce or over), we should raise the issue price of the rupee to one-and-six, and would, of course, retain our rupee currency." If such a pledge as that had been given years ago it might have prevented the action of France and the United States which have had something to do with the fall in the white metal. But there is an enormous and growing demand for the Indian rupee in Africa, and the abandonment of any serious design by India to introduce gold as a medium of circulation—it was tried, and failed miserably—is a further assurance that the call for silver increases.

THE SOUTHERN ARIZONA COPPER FIELDS.

Written for the MINING AND SCIENTIFIC PRESS
By C. F. TOLMAN, JR.

(Continued From Page 360.)

The Morenci-Metcalf copper deposits are situated in the northeastern corner of the copper region, in Graham county, about 20 miles from the New Mexican line, and south of the great plateau, here bounded by the White mountains. The mining of copper has given rise to three important towns: Clifton, a smelter city; Morenci, a mining and smelting town; and Metcalf, a mining camp, largely Mexican. These three towns house about 15,000 people, all directly dependent upon the copper industry. Of all the camps of Arizona, this group of mining towns probably affords the greatest interest to the casual traveler. The railroad journey to Clifton presents excellent exposures of the Gila conglomerate, which inspires speculation even among the uninitiated. I was asked if great volcanic explosions had not scattered the boulders throughout the gravels, while another man was of the opinion that ice was the transporting agent.

The trip from Clifton to Morenci on the ore-train and up the Longfellow incline will long be remembered, the town presenting a curious mixture of fine buildings, smelters, concentrators, mines, tunnels, and looping railroads. Down over the incline again and up the railroad to Metcalf, the variegated porphyry-walls of the canyon present a vivid study in red and ochre. At Metcalf, inclines take one up Shannon mountain, its sides scarred by open pits, and finally the ride up the Coronado incline, which rises 1200 ft. in 2500, and a short climb to the summit, back of the Coronado mine, gives a fine view of the water-scoured country below.

GEOLOGY.

The producing area stands like an island, above extensive volcanic formations and the Gila conglomerate, together forming a portion of the great mantle that was spread over much of southern Arizona in later Tertiary and Quarternary times. The local geology and the ore deposits are better known than those of any other copper camp of the country. This is due to the work of Waldemar Lindgren, whose treatise on these mines contains not only an excellent description of the properties, but has also proved to be the most important contribution to the knowledge of the processes by which the copper deposits of the Southwest are developed. One who has examined the geological mine-maps and sections now kept up by the Detroit Copper Co., is struck with the accuracy of Mr. Lindgren's work, considering the data then at his disposal.

Mr. Lindgren has shown that the district presents a pre-Cambrian basal formation of schists and an old granite; then overlying unconformably a thin series of Paleozoic quartzite, shales, and limestones, totaling only 1000 ft., topped again unconformably by a few hundred feet of Cretaceous shales and sandstones which are not mineral bearing.

The Copper mountain irregular intrusion (see Fig. 4), occurred either in later Cretaceous or early Ter-

tiary times, and is, therefore, of somewhat later date than the Bisbee intrusion which was pre-Cretaceous or very early Cretaceous. It has an even more irregular shape than the latter. It forced an irregular entrance into the older rocks, and the contact is marked by a cross network of outstretching dikes.

Mr. Lindgren's scholarly analysis of the orebodies shows many varieties of deposits, both in the sedimentary rocks and in the porphyries and granite, both contact deposits and a variety of vein formations. Scientifically all these are of interest, but economically the disseminated chalcocite in the porphyry is alone the important economic asset of the field. The geological mine-maps show clearly the irregular way in which the Copper mountain intrusion has broken up through the sedimentaries. The cross-cutting dikes develop especially in the Longfellow limestone and adjacent shale, and the

Fig. 5. Ryerson Group of Lodes.

Ryerson, Humboldt, Wellington, and Butler veins develop their large chalcocite orebodies in the porphyry, and are the wealth-producers at present. (See Fig. 5).

In general the chalcocite extends outward from fissures in the porphyry dikes and the main porphyry mass, but in the neighborhood of the contact, the fissure is often filled with a core of chalcocite, or chalcocite and pyrite. Although the pay-ore is confined to the fissure-zones, there is a disseminated ore, too low-grade to work, in much of the porphyry. The brilliantly stained porphyry in the neighborhood of Metcalf is said to assay from $\frac{1}{2}$ to 1% copper. The Morenci and Metcalf deposits are considered as related to the new larger type of disseminated ores, with this difference, entire rock masses are not pay-ore, only strips along fissure veins.

To give some idea of the size of these orebodies, one of the largest deposits opened is at the crossing

of the Humbolt and Ryerson veins, where a 300-ft. width of ore assayed 4% copper. Under ordinary conditions 2% is considered the lowest limit of pay-ore at present, and Norman Carmichael, manager for the Arizona Copper Co., states that 300 ft. is found to be the maximum thickness of the commercial chalcocite ore in Morenci. The outcrops of the great leads are singularly inconspicuous, strips of soft,

secondary sulphide zone is far above any permanent water-level, and while not disputing the evidence from which Mr. Lindgren deduces a water-level much nearer the surface in recent geological times, it does not seem necessary to postulate a definite water-level in order to have secondary sulphide enrichment. In the Old Dominion the secondary sulphides are found at a place far beneath the water-

Fig. 4.

leached, and slightly stained porphyry, hardly suggesting the wealth below. Mr. Lindgren's explanation on this point seems clear. Long-continued erosion has removed the original 'iron caps' that may have existed, while, migrating downward under the processes of secondary enrichment, the ore has accumulated, starting at a depth of 100 to 200 ft. below the surface. It is interesting to note that this

level, and in Cananea a case was noted where, on account of a thoroughly open, broken, hanging wall of an inclined deposit, the vein was leached from top to bottom along the hanging, while the secondary sulphides were deposited throughout the depth of the workings on the foot-wall. A high moisture-content in porous but fine-grained porphyry, seems sufficient to exclude oxygen and allow secondary reactions.

Another point noted that has interest in connection with theories of ore-formation, is that fine-grained disseminated chalcocite decomposes and oxidizes with great ease. Instead of being one of the most resistant of the sulphides, as stated by Mr. Weed, it is one of the most unstable under the attack of the oxidizing reagents. In Bisbee, sooty chalcocite, that was opened less than a year ago, was decomposing, and sulphate crystals half an inch long were seen. At Ray I was told of an engineer who entered some of the drifts, which were so covered with copper sulphate that the rock reflected blue to the candle. He refused to look further, saying that carbonate ores had no value. Had he rubbed off the sulphate crystals he would have seen the chalcocite underneath. Extensive development of the porphyry ores since Mr. Lindgren's examination has brought to light the fact that pyrite occurs above chalcocite. The explanation is evident. The chalcocite is less resistant, and is carried down more readily than the pyrite, the latter lagging above. Granular solid pyrite is reported 10 ft. above the chalcocite, and disseminated flakes of pyrite as much as 50 ft. above the top of the zone.

CORONADO VEIN.

The great Coronado fault-lode near Metcalf has a number of novel features. It is interesting to the transient visitor because its main geological features are written so plainly that they can be seen at a glance. The silicified breccia zone which marks the outcrop is along a fault of about 1200-ft. displacement, according to Mr. Lindgren. On one side the basal conglomerate of the Coronado quartzite can be seen, which on the other side caps the high summit of Coronado mountain. This splendid fissure vein averages 35 ft. in width, and the deepest working is reported to be 1000 ft. below the surface, showing a chalcocite orebody far thicker than any of the deposits at Morenci. The ore occurs in three shoots, namely, the Coronado, the Horseshoe, and the Boulder. The main developments are on the Coronado shoot, which has been proved for a length of 1500 ft. The matrix of the vein is ground and brecciated material, somewhat silicified, and carrying disseminated chalcocite. There are irregular patches of diabase in this crushed zone, and the evidence seems convincing that the diabase was introduced along the Coronado fault, and that continued movements crushed and stretched it out into irregular remnants. While possibly presumptuous for a casual visitor to take issue with Mr. Lindgren, who made such a laborious investigation of the field, it is difficult to see a genetic relation between the subsequent sulphide dissemination of the fissure and the earlier dike that intruded into the fracture, and was later crushed and mineralized. From a personal acquaintance with most of the important copper deposits of the Southwest, I have been forced to the conclusion that acid intrusives alone are capable of generating copper deposits in this region. Reasons will be given later for applying this to the Globe district, notwithstanding Mr. Ransome's conclusions in regard to the close connection between the diabase and the ore. On the 600-ft. level of the Coronado workings oxidized ore has been found below sulphide orebodies. The irregularity of

open fissuring that has caused the circulation of oxidizing waters under the sulphide zone above has not yet been discovered.

ECONOMIC CONSIDERATIONS.

The isolated situation of this field, the rugged character of the ground compelling the expensive railroad and gravity-tram construction, the expense of pumping water over a 1600-ft. lift to the concentrators at Morenci, the disposal of the tailing, and the scattered units preventing centralization and resultant economy, of necessity brings up the transportation and treatment charges, and the effort seems to be to offset this by lowering the mining expenses. This has led to the trying of some interesting varieties of caving methods. The increasing field offered by the Southwestern copper mines for the application of new mining methods makes it profitable not only to describe carefully each variety used, but also to discuss the advantages each may present.

MINING METHODS.

The top-slicing caving method is used by the Detroit Copper Co. to work out a triangular corner of ground between the claims of the Arizona Copper Co. and an old square-set stope, as shown in the figure. Cross-cuts are run on the sill floor 18 ft. apart, and raises are put up to the top of the ore at intervals of 25 ft. The top-slice of ore 8 ft. thick is taken out,

Fig. 6 Advancing Face, Top-Slicing Method.

the roof being supported by timbers, and a heavy mat of timbers is prepared. In taking-out each slice, a long-wall advancing method (to use a term borrowed from coal mining) is employed; the working face can be pushed out in any direction desired; the timbers being shot out behind when they show that they are taking weight. The upper slice is worked out before starting the second, and a layer of waste-boards is laid before shooting the timbers. Experience here shows that after the third slice the method is satisfactory and safe, but that during the extraction of the first and second slices the timbers have not yet been twisted into a mat, and unexpected falls of timbers out of the mat occur. As the number of slices taken increases, saving of timber can be made, for a thick mat comes down slowly and evenly, and some of the timbers can be pulled instead of shot. In this stope 18 ft. remained to be taken out before reaching a sill-floor. Instead of making two slices, it was decided to attempt removing it in one. This was done successfully, by using a temporary square set, and the mat was caved down on these timbers and then down to the floor, and after well started this thick slice was removed without difficulty.

ADVANTAGES OF THIS METHOD OF TOP SLICING.

The long-wall advance in any direction allows the

exploration of an irregular orebody, as long as the work is on the top of the ore. All the men are along a single working face, and this allows closer supervision. The ore breaks better than in overhead square-set mining, long lifters being possible in this case, and the product per man is therefore greater than in the square-set method formerly used. No saving in the amount of timbers can be expected until the operations are well advanced, but no careful framing is necessary, and they are placed much quicker than the square-set.

THE SUB-LEVEL METHOD; CAVING BY BLOCKS.

The operations may be summarized as follows: (see Fig. 7); (1) cross cuts 35 ft. apart from the main drift on the sill-floor; (2) raises every 30 ft., two-compartment, inside measurement 4 by 6 ft., chute 4 by 4, and balance the ladder way; (3) the sill-floor system of cross-cuts and drifts are repeated on each sub-level; the workings are directly over each other; the top 'sub' is about 30 ft. from the top of the ore; (4) cross-drifts are then run as shown in Fig. 7, dividing the upper 'sub' into blocks 35 by 30 ft. and 30 ft. thick; no mat is laid on top of

Fig. 7. Opening Rooms, Sub-level Method.

the ore; (5) each block is further divided by two cross-drifts, leaving four pillars to a block; (6) the pillars are sliced off on all sides, and the top of each raise blown out funnel shaped; (7) the roof is filled with holes; (8) at the first sign of weakening the pillars are filled with holes; (9) then a string of blocks, making a room 100 ft. long, are blown down. As many as 200 holes are shot at once; these are connected in multiple series, a single parallel not containing over 35 holes; the lighting circuit is used for the firing; (10) the roof stands arched, but no attention is paid to this, as the arch breaks after the second or third cave is made, and subsequent sections cave much better on account of the weight. The porphyry breaks in large blocks. Pieces 3 and 4 ft. diam. were noticed on top of the cave, but during the drawing and settling, the ore grinds itself up to such an extent that little trouble is experienced at the mouth of the chutes from large material. This method is an excellent one where the pillars will stand considerable slicing.

At the King mine in Metcalf, the special conditions

allow a cheap method of extraction. From the central drift running through the orebody, extraction-drifts are run into the country and around the ore, as shown in the sketch, and cross-cuts tap the ore. The orebody was completely under-cut, and caving started over the under-cut portion. The caving has proceeded satisfactorily up to the present, the cave confining itself to the portion under-cut, and the ore runs free for the shovelers stationed at the ends of the drifts, at A. This is the cheapest ore mined by the Arizona Copper Company.

FILLING METHODS.

A 'back' of ore 10 to 15 ft. thick is left above the main extraction-drifts and connections with the stopes are made by chutes. Above this 'back' a room is opened the width of the vein, averaging 35 ft. by several hundred feet long. Narrow pillars are left between the rooms, and these contain the man-ways. One-third of the ore is drawn, and the rest is left as a 'fill'. It is planned, on reaching the top of the ore, to lay a mat, cave the roof and pillars, and draw the ore. If the roof stands well, the ordinary method of drawing the ore and filling with waste may be adopted.

Summing up the changes made to meet the low price of copper, the following have been offered me

Fig. 8. Method Used at King Mine

by the men in charge: (1) The changes from the square-set to caving methods; (2) slightly raising the minimum grade of ore mined; (3) cutting down the exploration and dead-work; (4) besides these, the increased efficiency of labor, due to the hard times, has been perhaps the most important factor of all.

Paper money, first issued in 1881, has displaced gold and silver in Colombia, except small quantities of the latter, which are in circulation in certain districts remote from the capitol. Although reliable data have not been obtained, it may be concluded that the present outstanding issue of paper money is over ₱700,000,000, equal to \$7,000,000 gold, but some authorities place the amount as high as ₱1,000,000,000, equal to \$10,000,000 gold. The Government Mint, from August 1906, to June 30, 1908, coined silver to the amount of \$1,017,580, all in 30c. pieces, 0.835 fine. Some nickel coins, in ₱1, ₱2, and ₱5 pieces, have also been put into circulation during the past two years. No gold has been coined by Colombia in recent years. Some foreign gold is held by Colombian banks, and a limited amount thereof is in circulation, as well as foreign silver and bills. Exchange has steadily advanced from par, that is, ₱1 equal to 96.50 cents gold in 1874, to ₱189 equal to \$1 gold, in October 1902.

ZINC-BOX WHITE PRECIPITATES.

By ROY F. COOLIDGE.

*There seem to be two principal kinds of white precipitate; first, that containing large amounts of salts of cyanide, and second, that containing few or no salts of cyanide. The objection to this precipitate is similar in all plants, regardless of its exact nature, and as a rule the cyanide man will not admit that there are any white precipitates in his zinc-boxes. J. M. Tippet, chemist and metallurgist at the Portland mill, Colorado Springs, Colorado, describes the formation of a white precipitate in zinc-boxes as follows:

"A white precipitate forms on all the boxes at the head compartment, this condition being more pronounced on the weak side—in fact so great is the amount formed on this side that it necessitates a separation of this muck from the fine zinc when we clean up. It readily falls off when the zinc is disturbed. It consists of calcium ferro-cyanide, zinc hydrate, calcium sulphate, calcium carbonate, and fine slime from the sand filters. The formation of this white precipitate in such large quantities on the weak side is a rather curious fact, when it is remembered that the strong side carries the strongest percentage of lime. The only explanation I can give for it is that the solution is so weak in both cyanide and protective alkalis that it has not sufficient strength to hold it in solution when in contact with the zinc."

W. H. Virgoe, in a paper on the 'Consumption of Zinc in Cyanide Plants',† states that solutions of KCN containing zinc, that have been in contact with ore with which lime has been mixed, will gradually deposit in the sump-tanks a quantity of light, white precipitate, which forms first as a scum on the surface of the solution, and which consists of lime and zinc perfectly free from combination with cyanogen. This precipitate consists of carbonate of lime and zinc, the CO₂ coming from the atmosphere.

G. W. Williams states that "The well known white precipitate which forms in the zinc-boxes consists in the main of hydrated zinc oxide, together with a small amount of calcium carbonate and alumina. In addition to the above it always contains ferro-cyanides, often as much as 8%, and it is formed by the action of ferro-cyanide on freshly precipitated zinc oxide." Prister and Bay, in a paper on 'The White Precipitates Formed in Zinc Boxes at Cyanide Works', gives the following analysis and discussion:

| | % |
|---|-------|
| K ₂ Zn ₃ (Fe(CN ₆) ₂) | 10.45 |
| Zn(CN) ₂ | 22.73 |
| Zn(OH) ₂ | 54.79 |
| CuO | 0.40 |
| Fe ₂ O ₃ | 1.00 |
| SiO ₂ | 1.03 |
| Water (at 115°C.) | 8.07 |
| Loss on ignition | 24.72 |

"The loss on ignition is due to the loss of water

when zinc hydrate is present, decomposition of Zn(CN)₂ and K₂Zn₃(Fe(CN₆)₂ and to organic matter. The large quantity of zinc cyanide present in this white precipitate explains, first, part of the loss of free cyanide indicated by the difference in test from 'head' and 'tailing' of the same box; second, how the excess of zinc-salts is partly eliminated from the solutions. We found that the clean white precipitate contained 14.6% of CN corresponding to 35% of KCN, which is equal to 750 lb. of KCN in one ton of white precipitate."

The white precipitate treated in this paper was received from the Kendall Gold Mining Co., of Kendall, Montana. The ore is oxidized, silicious, is altered from limestone occurring in a formation near the intrusion of a porphyry dike. The analysis of the ore is as follows:

| | % |
|--------------------------------|----------------|
| Loss on ignition | 3.46 |
| SiO ₂ | 75.94 |
| Al ₂ O ₃ | 10.98 |
| Fe ₂ O ₃ | 1.89 |
| CaO | 3.15 |
| MgO | 1.94 |
| SO ₃ | 0.46 |
| | 98.33 |
| CO ₂ | 1.85 |
| Na } | |
| Ag } | traces |
| Au | \$4.80 per ton |

An outline of the treatment is as follows:

(1) Ore is crushed dry to 3/8-in. mesh and is placed in the tanks (dry) with 1 lb. of lime per ton of ore. (2) Tank is charged with strong solution (3 lb. of KCN per ton of solution) through the bottom of the tank. (3) Tank is leached with strong solution 144 hr. (4) First wash water run on tank. Strength 1.5 lb. KCN per ton of solution. (5) Second wash-water run on tank. Strength 0.5 lb. KCN per ton of solution. (6) Fresh water run on tank. (7) Tank drained 8 hr. (8) Tank sluiced 4 hr. Total time of treatment 10 days. The ore-value or tank-heads assay from \$3 to \$8 per ton.

The precipitation of the gold is by means of zinc shavings. The zinc-boxes used for the strong-solution are above the storage-tanks and consist of 8 double boxes. Each double box (4 by 14 ft.) contains two rows of 8 compartments each, 7 of which are packed with zinc and the last one used for settling. The size of compartments is 1 1/2 by 1 1/2 by 2 ft. and the bottom slope 1 1/2 in. per foot. Each compartment has capacity of 4 1/2 cu. ft., making an aggregate zinc-holding capacity of 520 cu. ft. The total weight of zinc in the above described boxes is 4420 lb., or 8 1/2 lb. per cu. ft. The amount of solution passing the strong boxes is from 800 to 1000 tons per 24 hours; or from 1.5 to 1.9 tons per cu. ft. of zinc-content. The zinc consumption is about 0.5 lb. per ton of ore treated, or 0.09 lb. per ton of solution in circulation. The zinc-shavings are cut from No. 9 sheet zinc, and are 1-1400 in. thick. The strength of the strong solution is 3 lb. of cyanide per ton and protective alkalinity from 0 to 0.2 lb. Very little lime is used, owing to the oxidized condition of the ore, and the absence of cyanicides. The boxes used for the precipitation of the weak solutions and the wash-water are four in

*Abstract from Western Chemist & Metallurgist, Vol. V, No. 8, Aug. 1909.

†Jour. Chem. Met. & Min. Soc. of S. Africa, Vol. IV, p. 91.

number, and are over the sump tanks. The amount of solution and 'wash' passing the above boxes is from 500 to 600 tons per 24 hr. Precipitation in both strong and weak boxes can be called good, as the head samples to the strong boxes run from 80c. to \$1.50 per ton, and to the weak boxes from 10 to 50c. per ton, while the tailing samples from both are less than 4 cents.

The zinc-shavings in the weak boxes become somewhat coated with the white precipitate, the analysis of which will follow. The weak boxes require as much or even more attention than the strong boxes, although this is not the practice at most plants. The total consumption of cyanide is in the neighborhood of 0.5 to 0.6 lb. per ton of ore treated. Both strong and weak-boxes are cleaned up twice a month and the method of procedure is as follows: fresh water is run into the head compartment to replace the cyanide solution, then the zinc is removed and the water is siphoned from the two head compartments into a settling tank 4 by 4 by 8 ft., as there are no discharge launders to the zinc-boxes. The slime is now removed from under the screen ($\frac{1}{8}$ -in. mesh); then the zinc is replaced and moved up as well as the solution from the lower compartments.

The water in the settling tank is allowed to stand 48 hr., then the bulk of water is siphoned off and run to waste, while the remaining water is siphoned into another small settling tank, and the fine slime taken up in buckets. The cut-down apparatus consists of a wooden tank (6 ft. diam., 4 ft. deep) provided with a hood and an electric-driven exhaust-fan, a pressure-tank, and a filter-press. Sulphuric acid is used for cutting down the product, the consumption being one bucket of acid to four of product. This is carried out in the usual way, adding the proportionate amounts of slime, acid, and water as the cut progresses. One feature of the cut-down that has proved exceptionally successful is the use of steam to heat the solution, near the end of the treatment, as the acid at this point becomes inactive, and the heating of the solution brings about a violent action. Hot washes are found much more effective than cold washes in dissolving out the soluble sulphates.

There are two kinds of white precipitates formed at the Kendall mill. White precipitate No. 1 is always found in the zinc-boxes to a greater or less extent, and is abundant when the mill solutions become foul with zinc and other salts. It is found most abundant in wash-water boxes where the strength of free cyanide is low, and when the gold value of the head samples to the boxes is low. It is light and flocculent, and floats in the boxes when the zinc is moved slightly. There is little or no protective alkalinity in the solution when it enters the zinc-boxes.

ANALYSIS OF WHITE PRECIPITATE NO. 1.

| | % |
|--------------------------------------|-------|
| Water at 100°C..... | 5.06 |
| Loss on ignition..... | 23.30 |
| *ZnO | 37.46 |
| SiO ₂ | 13.12 |
| Al ₂ O ₃ | 5.84 |
| Fe ₂ O ₃ | 1.55 |
| CaO | 3.62 |

| | |
|-----------------------|--------|
| MgO | 5.12 |
| SO ₃ | 4.42 |
| Au | 0.48 |
| Ag | trace. |

$$*Zn = 30.09 \quad Zn(OH)_2 = 45.74.$$

White precipitate No. 2 was taken from bottom of the acid-treatment tank after the gold-slime had been treated with H₂SO₄ and washed out. It is only slightly soluble in H₂SO₄ and undoubtedly comes from the white precipitate (No. 1) formed in the zinc-boxes. It is light colored, and heavier than precipitate No. 1. It is not hard to wash from the gold slime, although some of it is washed out with the gold slime and goes to the melting furnace.

ANALYSIS OF WHITE PRECIPITATE NO. II.

| | % |
|--------------------------------------|--------|
| Water at 100°C..... | 2.57 |
| Loss on ignition..... | 14.10 |
| ZnO | 2.07 |
| SiO ₂ | 1.69 |
| Al ₂ O ₃ | 2.32 |
| Fe ₂ O ₃ | 0.33 |
| CaO | 35.19 |
| MgO | 0.17 |
| SO ₃ | 39.65 |
| Au | 2.39 |
| Ag | trace. |

The analysis of the above white precipitate was made as follows: a weighed amount was treated with HCl and HNO₃ heated and filtered, and the residue fused with sodium and potassium carbonates.

The causes of the formation of this white precipitate may be very complex, but may be explained somewhat, after the chemical composition is known. Zinc is the principal element in these white precipitates and is present as the hydroxide. This is formed by the action of decomposed water on the zinc. The water is decomposed by the electro-motive force developed by the zinc-gold couple.

Calcium, iron, aluminum, and magnesium are found in small quantities in the white precipitates. The gold present is mechanically mixed with the precipitates. The objections to the white precipitates are many and in one year's time they add greatly to the cost of operation. They cause poor precipitation in that they coat the zinc shavings and clog up the screens. In plants where the cyanide radical is found in the white precipitates, the amount of cyanide lost in this way is large. In South Africa, Prister and Bay found 14.6% of cyanhydric acid which corresponds to over 35% of KCy or one ton of this precipitate would correspond to 700 lb. of KCy.

The consumption of zinc due to the formation of this white precipitate is also very great. The white-precipitate analyzed in my tests contained 30.89% of zinc, which is equivalent to 600 lb. of zinc per ton of precipitate. The cost of clean-up is somewhat increased as it is difficult to wash all the white precipitate from the slime. I made several tests on the solubility of this white-precipitate in KCy solution and found that it was quite soluble. This was reported to the cyanide man at the Kendall mill, who increased the mill solution to 3 lb. KCy per ton of solution with one pound protective alkalinity, and has just reported that he is now little troubled with white-precipitate.

SIMMER DEEP AND JUPITER REDUCTION WORKS.

Written for the MINING AND SCIENTIFIC PRESS

By J. E. THOMAS.

The joint reduction works of the Simmer Deep, Ltd., and Jupiter G. M. Co., Ltd., were erected and put into operation on September 1, 1908, to treat the ore from these two companies' mines, both of which are under the control of the Consolidated Goldfields of South Africa, Ltd. Separate mill-bins of 5460 and 2525 tons capacity are provided, the ore from each mine being treated separately until it leaves the mill-tables, when it mixes on entering the tube-mills and thence the cyanide plant. The recovery obtained by tube-milling and cyaniding is apportioned to each company on the basis of the tonnage and value of the tailing leaving each company's mill-tables.

Briefly the processes are as follows: breaking the ore to $1\frac{3}{4}$ -in. cube at each of the company's sorting and crushing stations; transport by means of hopper-bottomed cars of 35 and 45 tons capacity, drawn by a 48-ton locomotive on a 42-in. gauge track; stamp-milling with heavy gravity stamps of the Californian type, and amalgamation over stationary copper plates; tube-milling and amalgamation over copper shaking-tables; classification of slime and sand by means of cone-classifiers; treatment of sand by means of rotary filter-tables and wet-filling of tanks with cyanide solution, with subsequent transfer and percolation with cyanide solution; treatment of slime by the decantation process; precipitation of gold from solutions by zinc shavings, using zinc-lead couple; acid-treatment of gold-slime; calcining, and smelting.

The mill consists of 300 heads of stamps arranged five in each mortar, in blocks of 10, each 10 stamps being driven by a 50-hp. 3-phase electric motor. The current is generated and supplied by the Victoria Falls (Transvaal) Power Co., from their station at Brakpan, about 20 miles distant. The framing of the mill-buildings and bins is entirely of steel girders, the bins, themselves, being of timber 6 in. thick on the sides and 6 in. at the ends. The mortars are of the straight-backed type and are specially heavy, having a bottom 15 in. thick. Each weighs 11,872 lb. They are placed on concrete foundations, separate foundations for each 10 stamps, 17 by 10 ft. at the base and 15 by $4\frac{1}{2}$ ft. at the top and 10 ft. high. Each block contains about 102 tons of concrete, and has a sheet of best rubber $\frac{1}{4}$ in. thick between the bottom of the mortar and the concrete. The anchor bolts are 6 in number $1\frac{3}{4}$ in. diam. by $7\frac{3}{4}$ ft. long, so placed as to be readily accessible for tightening and replacing. The mortars are 6 ft. high, taking a 59-in. screen-frame. The height of the screen opening is 24 in. Each box has five 1-in. openings for the admission of water from the back-water service. These are so arranged as to give a jet of water playing on each die at an angle of 45° to the surface of the die. Manganese-steel liners are fitted in each box to take the wear due to attrition. The stamps weigh 1670 lb. each, when new, made up as follows: stem, 723 lb.; tappet, with gibs and keys,

252 lb.; head, 410 lb.; shoe, 285 lb.; stems are 4 in. diam., placed at $10\frac{3}{4}$ in. centres. The order of the drop is 1, 3, 5, 2, 4. The set height is $8\frac{1}{2}$ in. Height of discharge 4 in. and number of drops 100 per minute. The estimated duty per stamp is 8.7 tons per 24 hours, but this has already been exceeded using a 500-mesh screen, 0.033 in. aperture.

The king-posts are of timber of the 'built-up' type, to prevent twisting, and are seated in cast-iron shoes resting on the rubber on the concrete foundations. This also obviates an unnecessary amount of timber above the cam-shaft bearings. The cam-shafts are 16 ft. 3 in. long and 7 in. diam., and the majority are of the 'riffled Blanton' type. Other methods of fastening the cams on the shafts are also being used. The feeder-chutes are provided with sliding doors on the bins, while the feeders themselves are driven by means of $\frac{3}{4}$ -in. manila ropes from rocker-bars placed at the back of the king-posts above the cam-platforms. The front of the cam-platform is supported directly from the concrete foundations, independently of the king-posts. The reduction of the vibration on the platform, due to this method, is noticeable. The mill clean-up room is spacious and contains 3 revolving drums for cleaning amalgam; 3 amalgam barrels; 3 bateas, and a clean-up table sump. Besides these, a small tube-mill 6 ft. 6 in. by 5 ft., with a shaking table, two 10 by 10 ft. conical-bottom vats, and a precipitation-box, for the treatment of black sand, barrel, tailing, and the like by tube-milling and cyaniding, are provided. Two retorts and three Cornish fires are also in this room so that the amalgam is retorted and the bullion run into bars before leaving the mill-buildings.

The carpenters' and mill-fitters' shops are under the same roof as the clean-up room, but are separated therefrom by a fire-proof brick wall. The only entrance to the clean-up room is from the mill, past the mill-foreman's office.

The arrangement of the batteries back to back, 150 stamps on each side, with the bins between, admits of extensions being easily made at the southern end of the mill. The motors drive down to small counter-shafts, one for each 10 stamps, which are placed below the feeder and motor-floor, by means of 11-in. belts. Thence the drive goes direct by means of a 21-in. belt to the 7-ft. cam-shaft pulleys. The counter-shafts are moved by means of bevel-gear wheels, so as to take up the stretch in the motor and cam-shaft pulley-belts. On leaving the mill tables the tailing passes through mercury traps and launders to the tailing-pits, of which there are two, one for the 200 Simmer Deep, and one for the 100 Jupiter stamps. From there the pulp is elevated by means of 8-in. centrifugal pumps, three to one pit, and two to the other, only one in each pit being normally run at a time, to the cone-shaped tube-mill classifiers. Of these there are two to each of the four tube-mills, 45 in. diam. at the overflow and 7 ft. deep, with a $\frac{7}{8}$ -in. nozzle at the underflow. These, in turn, deliver into a de-watering cone, 36 in. diam., and 5 ft. deep for each tube-mill, with a $1\frac{1}{4}$ -in. nozzle at the underflow. The overflow from these de-watering cones joins the stream at the tube-mill outlets so as to make the re-ground pulp fluid

enough to pass over the shaking-tables; of which there are five, 12 by 4 ft. 7 in. to each tube-mill, and which run at 200 shakes per minute. The tube-mills are of the Krupp type, and are 22 by 5 ft. 8 in. inside in the shell, and are lined with 5½-in. local flint-sets. Each mill is driven by a separate 125-hp. electric 3-phase motor, and running at 30 rev. per min., takes about 104 hp. The pulp passes from the underflow of the de-watering cones through Pryce's feeders, through which are also fed the pebbles to maintain the pebble-load in each mill about 6 in. above the centre. These pebbles are pieces of ore about 4 in. diam. picked off the belts of the sorting stations, and delivered to a special bin from which they are trammed to the tube-mills in small cars of 10 cu. ft. capacity. The average working-load of pebbles, in each mill is about 10 tons, and about 5 tons per mill per day are fed in to maintain this. The tailing from the shaking-tables joins the main pulp in the tailing-pits and is re-elevated to the classifiers, any particles that still require re-grinding passing down again through the classifiers, the remainder overflowing with the fine product in the mill-tailing, to the cyanide works. A small lo-

Continuous Sand Collector.

comotive-type boiler is installed in a separate shed, outside the mill buildings, to provide steam for steaming plates.

Hand samples of the pulp entering the cyanide works are taken every hour at the overflow-launders of the tube-mill classifiers, and reserved for grading and assaying. The pulp is then run to 12 cone classifiers, placed in parallel, 6 ft. diam. at the overflow, and 6 ft. 6 in. deep with a 2½-in. nozzle and internal regulating plug at the underflow. The pulp overflowing from these classifiers flows directly to the slime plant, passing over 10 return-sand spitzkasten on the way. The underflow, containing about 4% slime, is pumped by means of a 6-in. centrifugal pump to the cones of the continuous sand-filter plant, with the addition of a little clear water. This plant consists of two rotary filter-tables 20 ft. diam., with a 2 ft. 6 in. filter-bed, equal to 137 sq. ft. each, revolving at a speed of one revolution every three minutes. The filter is composed of strong screen cloth, supported on wooden slats on edge, 4½ in. centres, over which is laid cocoa-matting, well caulked at the inner and outer edges. On this again are

placed strips of unbleached calico to prevent any slime, which may penetrate through the working-bed of sand, 1½ in. thick, choking the cocoa-matting. Over each of these tables four cones, 8 ft. diam. at the overflow and 8 ft. deep, are placed. The pulp overflowing after passing over two return-sand cones of the same dimensions, joins the main stream to the slime-plant. The underflow, containing about 30% moisture and 1% slime runs down launders of 30% grade on to the filter-beds. The under-

Tube-Mills and Slime Plant.

side of this bed is connected to a vacuum-pump, through a receiver, the moisture collecting in which is removed by means of a 3-throw plunger-pump, and returned to the main tailing-stream. A vacuum of from 5 to 10 in. is found most effective; if higher, the sand of the filter has become choked with slime and requires renewing. This is usually done once every 24 hr., the operation taking about 50 min. for both tables. Only three cones are normally in use for each table, the fourth being only used when the

Sand Plant and Filter Tables.

other table is out of action for renewal of the filter-bed or other parts. One table, working with four cones, is capable of dealing with about 60 tons of sand per hour for four or five hours. Both the primary and secondary cones are provided with diaphragms placed about 2 ft. above the underflow. The sand, containing about 15% moisture, is removed from the table by means of a plough, and falls into a launder in which a 0.03% KCy solution is running. Thence

it is elevated by means of a centrifugal pump to the collecting vats. Of these there are eight in use, two being utilized for storage and the other six for collectors. These vats are 50 in. diam. and 8 ft. 3 in. above the filter-mat, and are fitted with Butters and Mein distributors, and annular overflow launders. The solution overflowing the vat that is being filled runs into one or other of the storage-vats from which it gravitates back to the launder at the rotary filter-tables, and is again pumped up with fresh sand from the tables. Means are provided for removing any accumulation of slime in the storage to the slime-plant for treatment. Each collector-vat averages 738 tons of dry sand. After being filled and leached dry the charge is removed through 10 bottom-discharge doors on the three shuttle-belts which in turn discharge on to the main belt. These shuttle-belts are mounted on rails, and so arranged that they can be readily shifted from one vat to another by means of a traversing gear. Altogether there are six shuttle-belts 42 ft. centres and 32 in. wide for discharging the collecting-vats so that while three are being used the other three can be placed in position under the next vat to be discharged and so save time. The time required to empty a collecting-vat of sand is $3\frac{1}{2}$ hr., the shoveling, being done by 24 natives. From the main belts, of which there are two, one set 275 ft. centres and 28 in. wide, and the other 453 ft. centres and 28 in. wide, driven by two separate 20 and 50-hp. motors, the sand passes to another shuttle-belt 260 ft. centres and 32 in. wide, running on staging between the treatment-vats, 50 by 10 ft., arranged in two rows of five. From the shuttle-belt it is then discharged to Blaisdell distributors, two in number, each running on rails over each row of treatment-tanks. The sand is discharged from these after completion of treatment by means of 20 cu. ft. trucks fitted with side-jockeys and wire-rope mechanical-haulage to the two residue dumps.

The slime-plant is of the decantation type, and consists of four collector-vats 70 by 12 ft. deep at the sides with a cone 5 ft. 6 in. deep, equal to a flat-bottom vat 70 by 13 ft. 10 in. deep. There are also four first-wash vats, one intermediate transfer-vat and four second-wash vats, of the same dimensions. Each vat is capable of holding 400 tons of dry slime and 1400 tons of solution, and is fitted with a centre-valve which also contains a $2\frac{1}{2}$ -in. nozzle for solution to facilitate transferring and discharging of the slime-pulp.

This is accomplished by means of two 12-in. centrifugal pumps, with 16-in. suction and discharge-pipes. Only one of these pumps is used on any one vat at a time, but they are so arranged that either pump can be used on any vat for one operation, while the other is being used for another operation on any other vat. The first-wash solutions are decanted by gravitation to a small vat 20 by 6 ft. fitted with an annular overflow-launder. This allows of the settlement of calcium carbonate from the solution, which would otherwise choke up the cloths of the clarifying presses. The solution is pumped from this vat by a 6-in. centrifugal pump through three clarifying presses to a steady-head

tank; thence to the extractor-boxes. The second-wash solution can also be run through this system to the extractor-boxes if desired, but is normally pumped through a 6-in. centrifugal pump to the first-treatment vats or intermediate second-wash storage as required. This is of the same dimensions as the precipitated slime-solution intermediate-storage, namely, 70 by 12 ft., and is placed alongside it. The solutions from these storages is pumped through either of two 3-in. centrifugal pumps with 12-in. suction and discharge pipes, to any of the nine treatment-vats. A separate 6-in. centrifugal pump is provided to deal with the water decanted from the slime collector-vats. This water joins the stream from the annular overflow launders of these vats, and runs to the return-water vats, one 70 ft. by 16 in., fitted with an annular overflow-launder delivering into a second also 70 ft. diam. and 12 deep. This minimises the risk of slime remaining in suspension in the water returned to the mill. From the return-water tanks the water is pumped by three 8-in. centrifugal pumps to the mill-service tanks. Of these there are two, one 40 by 14 ft., and the other 40 by 12, mounted on staging 22 ft. high and arranged in the same manner as the return-water vats. Outside the extractor-house is a shed containing one vacuum and one 3-throw plunger-pump, used to assist leaching, and to aerate sand-charges while under treatment in either the collecting or treatment-vats. The extractor contains 20 steel zinc-boxes 30 ft. long and 5 ft. wide, each divided into two boxes of six compartments.

Twelve boxes are placed on the north side for dealing with solutions from the treatment of the sand. Of these, two are used for strong solution (over 0.05% KCy), the remainder being for weak solutions. One of the latter can be used for either weak or strong solutions, as desired. The other eight boxes are placed along the west side of the extractor-house near the clarifying-presses and deal with solutions from the slime-plant only. Each of the clarifying-presses contains 48 hollow frames 32 by 32 in., and gives 600 sq. ft. of filtering area, and is placed in a shed just outside the west side of the extractor-house.

The clean-up room for acid-treatment of the gold-bearing zinc-shaving from the extractor-boxes is in the middle of the extractor-house, the zinc-cutting lathes occupying the east side and the refinery the south side of the building. The extractor-boxes, clean-up room, and refinery are fenced in so that no unauthorized person may enter. The acid-treatment plant consists of three dissolving vats 10 by 6 ft. and three washing vats 10 by 10. These are all provided with mechanical stirring-gear. Bi-sulphate of sodium is used for dissolving the zinc from the boxes. This is dissolved in water in a lead-lined vat 10 by 10 ft., so as to give a solution containing about 18% free sulphuric acid. This is diluted with its own bulk of water before being used in the zinc-dissolving vats. The bi-sulphate dissolving-vat is placed at the south end of the shed containing the clarifying presses, with a small boiler of the locomotive type between. This latter is used for heating the bi-sulphate solution when necessary, and for obtain-

ing steam and hot water for the various small jobs, such as washing the cloths of the clarifying presses, washing the acid-treated gold-slime in the filter-presses, and so on. These filter-presses, of which there are three, 24 by 24 in., stand in the same room as the acid-treatment vats. The washes decanted from the acid-washing vats flow into two wooden vats 25 by 12 ft. where they are allowed to stand for several days, and, if necessary, treated with zinc-dust before being run to waste. The solution from the strong extractor-boxes runs into two steel storages 40 by 12 ft., that from the weak boxes into two 50 by 12, and the solution from the slime-boxes into one storage 50 by 12. Another storage of the same dimensions is also provided for surplus solution, that is, last drains from the sand-treatment vats, low in gold, waiting to be transferred to the slime-plant for the sake of its free KCy.

The refinery, which occupies the south side of the extractor-house, contains, besides a fluxing-room, one reverberatory pot-furnace capable of holding 26 No. 100 pots; one calcining furnace; one pan furnace for smelting slag, sweepings, and the like; one cupel furnace, and three Cornish fires for melting and casting the bullion into bars. As at the mill no gold-bearing material leaves the extractor-house except in the form of bars of bullion ready for depositing in the bank. All the furnaces in the refinery lead into one main flue 3 by 2 ft. 6 in. ending in an iron stack 90 ft. high by 5 ft. 6 in. lined for 40 ft. of its height with fire-brick.

The whole of the German output of cyanide, so far as can be learned, is controlled by the Deutsche Gold und Silber-Scheideanstalt, of Frankfort, which has agreements with the various manufacturers to take over their product, or to compensate them in some manner for keeping out of the market. Five different firms practically confirm the following written statement of one of their number: "I should advise you to apply for information to the Deutsche Gold und Silber-Scheideanstalt, in the hands of which, so far as we know, the sale of the production of all German cyanide makers is united." The concern mentioned has an American house, which controls the sale of German cyanide in the United States. Orders from Mexico are filled from Frankfort, and a Hamburg firm is the sole agent for Africa and Australia. From being a losing business, demoralized by low prices, the sale of cyanide has become a presumably profitable branch of the general business of the Deutsche Gold und Silber-Scheideanstalt, which, on March 31, 1908, according to the published annual report, paid 30% dividends on a capital of \$2,380,000, besides accumulating a reserve of \$1,856,400 and unpaid profits of \$238,000. The Frankfort company has relations with three American concerns, one of which sells its products in the United States. These companies, while suffering from a decrease in business, have been spared large direct losses, so that dividends as in the previous year could be paid. The Deutsche Gold und Silber-Scheideanstalt has established, or in part supported, eight concerns in Austria, France, Germany, and Switzerland. According to informa-

tion from reliable Hamburg exporters, it has been impossible, since the organization of this trust, commonly described as the syndicate, to buy cyanide in the open market for export to the United States.

OXYGEN IN COAL.

Recent investigations by the United States Geological Survey have shown that oxygen, so essential to all life, forms in coal an impurity that is almost as injurious as the ash content. The subject is of great importance to the consumer. David White, an account of whose investigations on the subject has just been published by the Geological Survey as Bulletin 382, was led to these conclusions by work undertaken in an attempt to devise classification of coals. He states that oxygen and ash are of very nearly equal negative value, ash being probably a little more injurious in most coals; and that the calorific value of coals in general is indicated by the balance between the total carbon on the one hand, and the sum of the two great impurities, oxygen and ash, on the other. The practical application of these statements appears in considering the effect of the exposure of coal to the weather. The weathering of the lower grades, especially lignites, bituminous coals, and peats, is marked by the accession of oxygen, which is taken into combination. This increase of the oxygen content causes a calorific deficiency, which is often serious. It is possible that in many cases considerable increase of oxygen and consequent loss of efficiency are suffered by the lower-class fuels after removal from the mine and before reaching the consumer, and it is probable that in the sub-bituminous coals, and more especially in the lignites, oxygenation begins immediately after the coal is blasted down. A comparison of the calorific values of the car and mine samples seems to warrant the apprehension that in some cases at least considerable deterioration occurs.

A series of investigations on the mineralogical composition of the best rocks for road building made by Edwin C. Lard, of the office of public roads, Washington, D. C., leads to the following conclusions: (1.) Igneous and metamorphic rocks, owing to a higher degree of crystallization, and a preponderance of silicate minerals, offer a greater resistance to abrasion than nearly all varieties of sedimentary rocks. (2.) The coarse-grained intrusive rocks of the igneous class are harder, but break more readily under impact than the finer-grained volcanic varieties of like mineral composition. (3.) The deleterious effect of atmospheric weathering on the wearing qualities of rocks has been demonstrated. (4.) The cementing value of rocks is, to a certain degree, measured by the abundance of secondary minerals resulting from rock decay. (5.) Metamorphic rocks have, as a rule, a low binding power, owing to a regeneration of secondary minerals, and to the effect of heat and pressure. The foliated types part readily along planes of schistosity, and, therefore, are not well adapted to road construction. (6.) The quantitative mineral analysis of rocks serves to a certain extent as a measure of their useful properties for road construction.

DEVELOPMENT OF MODERN THEORIES OF ORE-DEPOSITION.

By S. F. EMMONS.

*In my endeavor to trace the progress of thought in regard to the genesis of ore deposits, you must not think me too egotistical if what I have to say is considerably personal in its nature, for in such matters one cannot, to any great extent, assume the right to speak for others. When I first became connected with Government surveys, a little over 40 years ago, the people in the western United States, to whom it was necessary to appeal for the means for carrying on a Geological Survey, had little conception of the advantages and uses of such an organization, and a campaign of education was necessary to demonstrate its practical value. For 10 or 12 years such a demonstration was being carried on by the so-called Hayden, King, Wheeler, and Powell surveys, or geological explorations, as they might more properly have been denominated. Most of them appealed to the popular as well as to the scientific imagination, by their brilliant discoveries of such natural wonders as the geysers of the Yellowstone, the canyons of the Colorado, and the laccolites of the Henry mountains. The Geological Exploration of the Fortieth Parallel, which alone planned to make a geological map of a definite and limited area, secured its appropriation from Congress on the explicitly economic ground that it was necessary for determining the character of the mineral resources of the mountainous regions to be made accessible by the recently authorized trans-continental railroads. In furtherance of the plan of popular education, Clarence King, its organizer and chief, pushed to immediate publication the economic results of the work, the study of actually developed mines, including the Comstock lode, set forth in the volume on Mining Industry, which appeared in 1870, seven years before those embodying the more abstract scientific results which had to wait the completion of the researches of specialists. The realization of the ultimate object that the geologists of the Fortieth Parallel Exploration had in their minds during the ten years spent on that work came earlier than had been anticipated, when in 1879 all existing geological explorations were consolidated into a permanent Geological Survey, which was organized as a bureau of the Interior Department, and there is little doubt that the practical demonstration of the utility of such work furnished by the Mining Industry volume had much effect in rendering Congress favorable to the new organization. Mr. King, as its first director, in recognition of the legitimacy, in an industrial country like the United States, of a demand for the practical application of geology to the development of its mineral resources, established a division of Mining Geology, and devoted about half of the first year's appropriations to economic studies of mining districts, comprising the Comstock lode, the newly discovered Leadville district of Colorado, and the copper deposits of Lake Superior.

The organic law establishing the Survey had lim-

ited its operations to the National domain, leaving it uncertain whether this meant only the public lands in the West, still belonging to the Government, or the whole area of the United States. Until Congress explicitly authorized the former construction of the law, Mr. King's idea was, by multiplying the surveys of mining districts, which involved the making of special topographic maps for each district, to demonstrate to the mining community the practical usefulness of the work, so that in time the people would demand of their representatives in Congress its extension over the whole country. At the same time he expected that the large corps of observers, trained especially for this work, would accumulate a fund of scientific data with regard to ore deposits from which in time a new and more satisfactory theory of vein-formation could be formulated, and thus confer an even greater benefit upon the mining community.

J. W. Powell, who succeeded Mr. King, accomplished by indirection the construction of the law that Mr. King had failed to obtain directly. The making of a geological map is evidently the first duty of a geological survey, but this had not been explicitly mentioned in the organic law. In the paragraph of the bill making the annual appropriation for the Survey he succeeded in having this clause inserted: "and for making a geological map of the United States," so many dollars. When this had become law, he found himself not only authorized to extend his work over the whole United States, but reasoning that an indispensable preliminary to a geological map is a topographical base, he also felt authorized to have a topographical map of the whole United States constructed. As such a map of the United States would cost at the lowest estimate about \$30,000,000, it would evidently have been of doubtful advisability to ask Congress for it directly. Mr. Powell did not place as much importance on mining geology as did Mr. King, and during his administration, work in this branch rather languished, topography, geology, and irrigation absorbing the greater part of the survey-funds. Nevertheless, during his time Becker accomplished his investigation of the quicksilver deposits, and commenced that of the 'gold belt' of California, in which he was assisted by Waldemar Lindgren, while R. D. Irving and Charles R. Van Hise began the study of the great iron ores of the Northwest.

The Leadville monograph, owing to the peculiar relation of ore deposition to structural geology in that district, had served in a striking manner to illustrate the practical use of applied geology in the working of mines, and had thus served as a great educator of the miner as well as of the mining engineer, and made the work of the Survey popular. Although I was not allotted sufficient funds to undertake during this time the study of other great mining districts on a similar scale, I was able, by reconnaissance-studies, to keep in touch with the more important mining developments throughout the Rocky Mountain region, and by occasional articles in the Transaction of the American Institute of Mining Engineers to keep up the interest of the mining community in the economic work of the Survey, while

*Abstract of address before the Canadian Mining Institute, 1909.

continuing the geological education of the mining engineer. In 1892 the Survey appropriations were cut down a third as the result of an attack made upon the floor of Congress by the Western interests that felt themselves injured by the legislation that had been brought about as a result of the irrigation investigations carried on by Mr. Powell under the auspices of the Survey. Although the men who directed this movement were particularly friendly to the economic branch of the Survey, and had thought to benefit those who were carrying it on, their legislation had exactly the opposite effect, for this provided for the reduction of the number of chief geologists from five to two, but as the law specified no individuals, it fell to the director to designate who should be dropped from the pay-rolls, and his choice fell upon those who had been engaged in economic work. Although we could do no official field work, Mr. Becker and I, however, continued our office work, writing up several reports during the interregnum. With the appointment of Chas. D. Walcott as director in 1894, the economic work of the Survey was revived and given a new lease of life. Not only were we restored to our positions, but we were allowed to recruit the force by the accession of younger men admitted from time to time by competitive examination, so that it came to include the now well known names of F. L. Ransome, J. E. Spurr, W. H. Weed, A. C. Spencer, J. D. Irving, J. M. Boutwell, L. C. Graton, and others. The field of work correspondingly widened, and was later extended to the investigation of the non-metallic minerals under C. W. Hayes, of which, however, I shall not now have time to speak. The accumulation of knowledge under these more favorable conditions has proceeded in a sort of arithmetical progression, so that at the present time there is no important mining district in the country, of whose geological structure the Survey has not some definite knowledge, whether through special or reconnaissance-surveys.

The whole period of investigation forms part of what I have called the period of verification, characterized by attempts to test by practical application to the facts of Nature, theories or hypotheses that had already been proposed, rather than to propound new ones. This was peculiarly true of the first decade when the workers were few and they were entering upon a field of work in which their knowledge was yet to be gained. The first innovation was in extending the methods of detailed surface geological study to the subterranean areas disclosed by the drifts of large numbers of mines. The generalizations first made were those that seemed necessary at the close of each specific piece of work, to show to the miner the conclusions deducible from the geological facts already determined, and the practical bearing they might have upon the conduct of his mining operations. For myself, in my first report (that on Leadville), while drawing conclusions as to what I designated the immediate source of the ores and the manner in which they had been deposited, I specifically disclaimed intention of discussing the ultimate source from which the metals were derived, or of propounding general theories of ore deposition. In the papers, communicated from time to time to the

American Institute of Mining Engineers, I laid stress on the structural relations of the deposits, or the observed facts and generalizations bearing upon the form and nature of the rock channels through which the mineral-laden waters brought in their ores. Reference was also made to other conclusions with a more theoretical basis, which had been criticised as novel and untenable, and which we not only felt bound to defend, but often, as the result of new studies, we wanted to extend in their application. Most prominent among these were those of metasomatism or replacement in the formation of ore deposits, and the genetic connection of ore deposits with eruptive rocks. The former was in those early days regarded as a hobby of mine, because, while all who had occasion to test it in the field were ready to admit that it, rather than cave-filling, was the process by which ores in the limestone were generally deposited, when I maintained, as a result of later studies, that in vein-deposits in the West, a considerable portion of the vein-filling is the replacement of country rock by vein materials, rather than, as had hitherto been held, the filling of pre-existing open spaces, many geologists, including my colleague Mr. Becker, seemed inclined to think I was going too far. That eruptive rocks and ore deposits are commonly associated in Nature, had been remarked by geologists before it was observed by us in the course of our economic studies, but in order to determine whether this connection was genetic, rather than merely a fortuitous association, we endeavored to determine by careful chemical tests whether the fresh unaltered eruptive rocks contain the metals and other materials that went to make up the ore deposits we were studying, following in this the suggestion of Sandberger, who himself had followed that of Bischoff. We were identified to some extent with the 'lateral secretion' school that Sandberger had founded, and were assumed by some of our critics to maintain that the waters we thought had obtained their vein materials from the eruptive rocks, were cold descending waters. In point of fact, however, I by no means believed, as he did, that the vein-materials were necessarily derived from the immediate walls of the deposits, and since I showed that the deposits at Leadville had been formed under a covering of 10,000 ft. of sedimentary beds, it could hardly be said that the waters that formed them were directly descending from the surface. What I did maintain was that if, as the results of our chemical tests seemed to indicate, they were derived from igneous rocks while cooling, it was from such masses as had cooled within a reasonable distance of the place where the deposits were found. My main point of difference with the so-called ascensionists was that they maintained that all ore deposits are formed by waters ascending from the unknown depths or barysphere, where, owing to an assumed greater density the rock masses must be richer in the heavy metals than those observed at the surface, which possess only about half the density of the earth as a whole. Inasmuch, therefore, as these waters were assumed by them, as by all geologists at that time and indeed until the end of the second decade, to be meteoric waters descending under the influence of gravity, to rise again

under the influence of heat, their assumption seemed to involve an evident impossibility. Long before these waters could reach a zone where the rocks had the requisite specific gravity, which must be many miles below the surface, they would reach a region where the pressure would be so great that open cracks which would admit of their circulation would no longer be possible, a condition that Heim in his researches on the mechanics of mountain-building in the Alps had determined would exist at a depth of 5000 metres. It seemed more probable, therefore, that these waters had derived their vein-materials from cooling igneous masses within reasonable proximity to the surface, since chemical tests had proved the actual presence of these materials in some of the fresh rocks tested, whereas similar tests of sedimentary rocks had found none. The chemical tests I depended upon were made by Hillebrand in a laboratory which, under King's authority, I had established in Denver in 1880. In the laboratory which Becker had similarly established in San Francisco, he and Melville had made further investigations in the course of his study of quicksilver deposits, to determine the natural solvents which would have enabled the circulating waters to take up the vein-material that formed part of the rocks they were traversing.

About the middle of the decade the chemists of both these laboratories were transferred to Washington, and the laboratories themselves soon afterward abandoned, so that under the pressure of other work this line of investigations was gradually dropped. Indeed until the studies of petrologists and physical chemists had thrown more definite light on the probable conditions prevailing at some depths beneath the surface, further speculations along this line seemed rather profitless. Finally, in the latter part of the decade, the conclusions arrived at independently by J. P. Iddings in this country and Brøgger in Norway with regard to differentiation in igneous magmas, showing how different varieties of rocks might proceed successively from the same deep-seated molten mass, combined with the discovery that certain titaniferous iron ores in Norway were actual segregations in a cooling magma, seemed to afford a line of argument which was most suggestive, and of which I made use in an article I prepared, during the interregnum, for the Chicago Exposition meeting of the American Institute of Mining Engineers on the 'Geological Distribution of the Useful Metals in the United States'. My line of argument was that since actual proof had thus been afforded that certain metals like iron had been concentrated in given parts of an eruptive magma, the same might be true of the other metals, though it would be less susceptible of proof on account of their smaller proportion among the constituent minerals of rocks. Hence among the different rock-forming magmas that from time to time came to cool within a limited distance of the surface, and thus within reach of the circulation of meteoric waters, it might be conceived that certain magmas, as a result of this process of differentiation, would be rich in gold and silver, others in copper and zinc, or other metals. Thus on the theory that ore deposits are the result of the leaching of bodies of eruptive

rocks, one could understand why one set of deposits contains mainly one combination of metallic minerals and another another, and some regions, where eruptive rocks abound, contain little or none.

Posepny's well known article on ore genesis presented at the same meeting, while it gave an admirable description of the processes involved in ore deposition, and contained the strongest and most definite arguments yet presented in favor of the ascensionist theory, and in disproof of Sandberger's theory of lateral secretion, did not touch upon the difficulties we conceived to stand in its way from the inaccessibility of the barysphere to descending vadose or meteoric waters. He evidently conceived of no other source for the waters circulating within the earth's crust, and was more than insistent in his belief that practically all ore deposits have been deposited from aqueous solution, and are later than the enclosing rocks.

During the second decade my mental attitude toward these more speculative theories was still a waiting one, and I busied myself as before with those more capable of actual proof and of direct practical application to mining. A question of the utmost practical importance to the mining industry and which had often been propounded without receiving satisfactory answer, was whether vein deposits increase or decrease in value with depth, and I was most desirous of obtaining scientific evidence in favor of either conclusion. In the Leadville work it had been recognized already that an enhancement of values takes place in the oxidized zone, in part by removal of the baser and less valuable metals, and in part also by actual transference downward of the silver salts, but this action was supposed to necessarily come to a stop at the ground-water level. In the summer of 1896, during a study of the Butte mines, I discovered definite and unmistakable geological proof that this transference has continued for some distance downward into the zone of unaltered sulphides, thus explaining the formation of bonanzas in the middle depths of many mines, and the frequent prevalence of low-grade ore in depth beyond their reach. Appreciating at once the far-reaching practical importance of this theory of secondary sulphide enrichment, as I called it, I did not wish to publish it until I had satisfied myself as to its general applicability to all classes of deposits, and had discovered a satisfactory explanation of the apparently abnormal chemical reactions involved, which, as pointed out by Mr. King during our frequent discussions of the subject at Butte, formed the weak side of my theory. During several seasons' field work, therefore, I took every opportunity of confirming the operations of this process in other mining districts, making in 1898 a special examination of all the important copper deposits of the West, and finding a remarkable uniformity in the succession of copper minerals with depth that could only be explained on this theory. At Mr. King's suggestion, moreover, I had chemical literature searched for records of reactions that might be supposed to account for the observed mineralogical changes. Some further experimental tests in the Geological Survey laboratory were still desired to be made, when it was

announced that Walter Harvey Weed, who had been associated with me in the Butte survey as surface geologist, was to read a paper on this subject in the winter of 1899-1900. I then learned that, prompted by suggestions gathered during our discussions on the subject at Butte, he had since been making a practical test of the theory himself in certain silver mines of Montana.

At the winter meeting of the American Institute of Mining Engineers there were read, singularly enough, besides the respective papers of Mr. Weed and myself on secondary enrichment, which presented the results of our practical studies in the mines, a more theoretical discussion of 'Some Principles Controlling Deposition of Ores', by Charles R. Van Hise, in which independently, and from a somewhat different point of view, he had arrived at practically the same conclusions with regard to the secondary enrichment of sulphides by descending waters. Mr. Van Hise's article contained an admirable exposition, founded on careful experimental studies, of the manner in which meteoric waters circulate within the crust, and cleared up many points left uncertain by Posepny's earlier explanations, but like him he considered the vast majority of deposits to be epigenetic, and formed through the agency of meteoric waters, practically ignoring, as Mr. Lindgren later pointed out in his article on contact metamorphic deposits, presented at the Richmond meeting of the institute, the important contact deposits of the Kristiania type. It is true that up to 1900 none of us, except possibly Mr. Lindgren himself, had given as much attention as was deserved to this class of deposit. The Kristiania deposits, and indeed most of those in Europe and elsewhere that had been recognized as belonging to the same type, were of little economic importance.

The most decided reaction against the Van Hise-Posepny view presented at the Richmond meeting was contained in James F. Kemp's article on the rôle of igneous rocks in the formation of ore deposits, in which he ascribes the principal rôle not to meteoric waters, as Mr. Van Hise had done, but to waters proceeding from the igneous rocks themselves, hence called magmatic waters. In addition to this forcible theoretical argument in favor of magmatic, rather than meteoric waters, as conveyors of vein-materials, Mr. Kemp quoted several facts of observation showing that the bottom levels of deep mines are generally found to be dry, and hence argued that meteoric waters do not penetrate to depths of over 2000 to 3000 ft., and consequently could not act as conveyors of vein-materials from the depths. Mr. Kemp's contention received unexpected support from an announcement by the great Austrian geologist, Suess, at a Balneological convention at Karlsbad in 1902. In his address Suess stated his belief that the waters of certain thermal springs of Europe which have long been the subject of careful chemical study, are derived not from descending meteoric or vadose waters, but have their source in cooling eruptive magmas, and as they reach the surface for the first time in these springs he denominated them 'juvenile' waters. To this origin he ascribed the vapors poured out by active volcanoes, which had hitherto been supposed to be fed by sea waters percolating downward

through the rocks and meeting the rising lava-stream. Springs then, he classified, by the source of their waters, as juvenile and vadose, and those that are fed in part by waters from both sources. A certain amount of verification of these views is found in the permanence of composition of the springs classed as juvenile, and their independence of variations in the amount of precipitation in the surrounding regions.

Mr. Kemp's views were in the same general line, though a step in advance of the views maintained by the Norwegian geologist, Vogt, who, since 1893, had been advancing a constantly widening applicability of magmatic or pneumatolytic origin to ore deposits, and whose views had been adopted by a number of geologists on this side of the water. Hence Mr. Kemp's article met with very general favor. That among those who are ready to accept the prevailing theory, whatever it may be, for the explanation of the ultimate origin of the deposits they may have occasion to study, this latest explanation has met with such universal acceptance, is hardly surprising. If accepted it removes at once all the objections that have heretofore obtained against either the ascension or lateral-secretion forms of theory. It is a return to the catholic faith of the earlier days, as far as the source of the metals in the unknown depths is concerned, a faith that has been strengthened and rendered more specific by such positive evidence as has been obtained with regard to thermal springs, and the negative evidence of the aridity of such deeper parts of the crusts as have come within the range of direct observation. I will not trespass upon time by discussing the pros and cons of the modern popular theory of the magmatic origin of all ore deposits, with regard to which I can claim no special familiarity. I fully admit its attractiveness as a method of removing the obstacle to deep circulation presented by increase of pressure with depth, since if the *vis a tergo* is sufficient to force up molten lavas across the zone of flowage, the same force ought to suffice for aqueous solutions. One of the points on which I still maintain a doubting position, however, is as to whether we have definite proof that magmas contain enough water to afford the continuous flows needed to supply thermal springs as well as ore deposits. The study of contact metamorphic deposits has afforded some definite proof that certain magmas have given out aqueous solutions (whether in gaseous or liquid form is not essential), that have actually contributed to the surrounding rocks supplies of metallic minerals, but this action was geologically brief, and differs from that involved in affording the continuous supply from great depths predicted by the conditions that obtain in thermal springs, or in the greater accumulations of metallic minerals such, for example, as Leadville and Butte. Before we can assume the sufficiency of this source for subterranean waters we must await further developments from the profound and necessarily deliberate labors in the realms of physical chemistry, such as have been and still are being carried on by F. B. Adams in Montreal, and by Messrs. Becker, Day, and Wright, at Washington, and the results of more such searching geological investigations, as those of Mr. Lindgren, on the contact metamorphic deposits of Clifton-Morenci.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

OIL AND GAS LEASE—CONSTRUCTION.

A written instrument granting all the oil, gas, coal, and asphaltum under certain described land, which was designated a lease, and had a definite term of years and provided for the payment in cash of a stated amount, and also for the payment of a royalty on all oil produced, was construed to be a lease and not a conveyance in fee of the mineral in place.

Moore v. Sawyer, 167 Fed. 826, Jan. '09.

OIL LEASE—PRIORITY.

An assignee of a second oil lease on Indian land, who took the assignment of such lease with knowledge that a prior lease was outstanding, but which had been forwarded to the land office for cancellation at the request of the parties, was not regarded as a bona fide purchaser entitled to preference over such prior lease, where such prior lease was not in fact cancelled, but was approved by the Secretary of the Interior, as the request for cancellation had been made through a mistake, which fact the assignee could have ascertained by making inquiry of the parties.

Moore v. Sawyer, 167 Fed. 826, Jan. '09.

INJURY TO MINER—CONTRIBUTORY NEGLIGENCE.

Where a coal mine was so free from gas that lamps were used, but there was an accumulation of gas in a particular pocket, a miner sent to work in that particular place, and who approached the same with an open light, was not entitled to recover for injuries received by an explosion from gas ignited by his light. Where he knew that there was an accumulation of gas in the particular entry and approached the same with an open light he assumes the risk incident to the service.

Bisko v. Brasnel Coal Co., (Pa.) 72 Atl. 504, Jan. '09.

LOCATION OF MINES—DISCOVERY SHAFT.

Where the original discovery shaft on a lode mining claim was sunk 10 ft. deep, as required by law, and the portion within the boundaries of the claim was large enough to enable a miner to work within the boundaries, the fact that a part of such shaft was in ground operated on an adjacent patented claim was immaterial. The fact that the shaft was partly within the boundaries of another claim was of no consequence where that portion which was within the boundaries of the disputed claim was of such dimensions that it was in reality a shaft sunk upon that ground. The law does not attempt to prescribe the extent of any dimension of the discovery shaft, except the depth.

Nichols v. Williams, (Mont.) 100 Pac. 969, Apr. '09.

JOINT AGREEMENT TO PURCHASE MINING CLAIM—PURCHASE BY ONE AFTER EXPIRATION OF OPTION.

A prospective purchaser contracted with two persons who held an option for a mining concession in Mexico that if they would get an extension of the option in order to give time for the sinking of a shaft he would furnish the necessary money therefor. The holders of the option secured its extension on condition that an advance payment of \$5000 should be made, and demanded payment of the other party of his share of such advance payment, which was refused, and thereupon the holder of the option permitted it to expire. Subsequently one of them immediately obtained a new option to himself under which he afterward purchased the property. In an action by such third person to establish a trust in the property, it was decided that the contract created no such fiduciary relation between the parties as prevented the option holder from treating it as at an end, and that a subsequent purchase by one raised no resulting trust in favor of such prospective purchaser.

Gaines v. Chew, 167 Fed. 630, Feb. '09.

American Mining Congress.

A partial list of the speakers who will appear on the program for the Twelfth Annual Session of the American Mining Congress, at Goldfield, Nevada, September 27 to October 2, appears below. The Program Committee has not yet completed its work, and this list will be materially augmented before the final program is published:

1. Purchasing Coal by the B. T. U. Method: By Samuel A. Taylor.
2. The Paralysis of Mining Districts: By E. B. Kirby.
3. The Forest Reserves and Other Public Land Questions: By Welden B. Heyburn.
4. The New Experimental Ore Dressing and Metallurgical Plant of the Colorado School of Mines: By F. W. Trap-hagen.
5. Industrial Accidents and General Liability Laws: By David Ross.
6. Old Days on the Comstock: By William C. Ralston.
7. State Inspection of Metal Mines: By Courtenay De Kalb.
8. Some Defects in State Inspection of Mines: By Harry A. Lee.
9. Zinc Mines in the Good Springs District: By Douglas White.
10. Geology and Ore Deposits of the Round Mountain District: By J. P. Loftus.
11. Some Grievances of Ore-Producers Against the Smelting Combine: By James H. Fox.
12. The Geology of the Goldfield District: By Charles J. Moore.
13. Some Arizona Suggestions in Mining Law Revision: By Fred J. Elliott.
14. Protecting Mine Investors: By Floyd Davis.
15. The Florence Mine: By A. D. Parker.
16. The Bullfrog Mining District: By Clay Tallman.
17. The Ely Mining District: By S. W. Belford.
18. The Application of Steel to Mining: By R. B. Woodworth.

19. The Effect of Silver Values Upon American Trade with Silver-Standard Countries: By James A. Heckman.
20. A Bureau of Mines: By D. W. Brunton.

Additional views upon the silver question will probably be offered by Moreton Frewen, James J. Hill, and John Hays Hammond. Officials of the Mexican and Canadian Governments are also expected to be present and take part in this discussion.

Special discussions will follow the committee reports upon the following questions:

- The Prevention of Mine Accidents.
- A Tonnage Tax on Coal Output for Distribution Among the Victims of Mine Accidents.
- The Standardization of Electrical Equipment in Mining Work.
- Needed Changes in Alaskan Mining Laws.
- The National Forest Service.
- Vertical Side-Line Laws.
- General Revision of Mining Laws.

Sessions will begin at 10 o'clock Monday morning, September 27, and adjournment will be on Saturday afternoon, October 2. On Wednesday the sessions will be held in Tonopah, the citizens of that city providing a special train to convey the delegates from Goldfield early in the morning, returning in the evening.

Commercial Paragraphs.

THE CANTON BOILER & ENGINEERING CO., Canton, Ohio, has just received an order for a steel stand-pipe, 25 ft. diam. by 100 ft. high, for erection at East Gardner, Massachusetts.

FALKENBURG & LAUCKS, assayers and metallurgists, Seattle, Washington, have issued an instructive, useful pamphlet on the sampling, testing, and specifications of cement. They have added a cement laboratory to their plant.

THE UTAH MINING MACHINERY & SUPPLY CO., Salt Lake City, announces that the name of the concern has been changed to the Galigher Machinery Co. There is no change in the officers or management of the company, but the capitalization has been increased.

EDITORIAL.

GOLDFIELD claims the greatest gold mine in the world. If necessary two Esquimaux will be produced to swear to it.

THE tariff is proving indeed a work of art, and the can(n)ons of art are the expression of the preference of those interested.

COPPER mining on Prince William Sound, Alaska, is rather quiet now, though development goes steadily forward and shipments are expected this fall.

THE breast of the Newhouse tunnel was advanced 338 feet in August; an excellent record for two-shift work in gneisses and schists. The tunnel is now in nearly 20,000 feet, and is well under the most productive portion of Gilpin county, Colorado.

DIFFICULTIES between China and Japan over railway matters in Manchuria are settled, but the full text of the agreement has not been made public. To commercial interests the important thing is that the Antung-Mukden road is to be improved without delay so that it will become a real transportation route.

THE Geological Survey report upon Goldfield has been issued and makes a handsome appearance. Mr. F. L. Ransome is senior author. He was assisted in the work on the district by Mr. W. H. Emmons and Mr. G. H. Garrey. The report will be especially welcome to the large number of visitors attending the meeting of the Mining Congress.

ACCORDING to the plans carefully worked out in the daily newspapers in this country, the Mexican revolution was to have burst forth in lurid flame on Independence Day, September 16. It has passed off in a most quiet and decorous manner. Likewise the massacre of foreigners in Mexico on September 16, 1906, was accomplished through the newspapers without bloodshed. Meanwhile the building of railroads by the Southern Pacific and the Pearson capitalists proceeds. The great Necaxa dam is continuing under the supervision of Mr. James D. Schuyler, while Mr. John Hays Hammond, in the face of all this revolutionary talk, calmly lays down a small fortune as option-forfeit upon the Santa Gertrudis mine.

COAL miners have been criticising Mr. E. W. Parker's report on the coal production of Alabama because he said that the suspension of work was the result of an effort by the United Mine Workers to strengthen the organization in that State. Since the offending phrase was based on an official letter issued by the International Executive Board of

that organization June 30, 1908, the criticism appeals to us as unfortunate. Much might fairly be said as to the need of Alabama miners for organization and of the unfortunate condition of the particular miners involved. It does not, however, help a lost cause to criticize a public officer for stating facts, particularly when they are so easily verified.

Opening New Gold Territory in Peru.

Announcement is made of a concession granted by the Peruvian Government to the German house of Koppel for a trans-Andine railway, starting from the port of Paita in the northern part of the Republic, passing up the valley of Piura, and crossing the divide approximately at the point where the Amazon, locally termed the Marañón, changes from its northerly course and turns toward the east. This was pointed out by travelers twenty years ago as being the most feasible route across the mountains, the elevation at the summit of the pass being only 7000 feet above tide. This is the lowest depression in the Andes between Popayán, Colombia, and the Paso de los Andes between Cautín, Chile, and the Nequen Territory in Argentine. It is said that with some tunneling the maximum elevation on the Piura route can be reduced to less than 5000 feet. On the west side the line would pass through a region already famous for its oil and sulphur, and for a peculiar long-staple cotton that has for decades commanded double the price of sea-island cotton in the markets of England and the United States. Passing the western range, the road would at once enter the valley of the Amazon in its inter-montane section, which it would follow for about 200 miles, passing the mouths of many rivers already celebrated for rich gold placers. Chief among these is the Utcubamba, which contains a large amount of rich ground, suitable for hydraulicking, as well as areas which will be available for dredging as soon as the railroad may admit of the economical transport of machinery. Farther down the river, just above the great falls of the Amazon, known as the Pongo de Manseriche, the San Lorenzo river empties into the main stream from the north. This river rises near Cuenca in Ecuador, and traverses a great area of schists, filled with small gold-bearing quartz stringers. These afforded alluvial deposits, furnishing rich cream to the early *conquistadores*, nourishing skim-milk to the gold-washers of the last century, and are still yielding whey from which the skilful can extract some pleasant *requeson*. A remarkable feature of the San Lorenzo is the existence of an area of sandstones from which metallic mercury has been contributed to the gold-gravels, resulting in native gold amalgam for many leagues. Below this come other areas of schist yielding gold which has enriched large areas of valley-land near the mouth of the river. The projected railroad will open up a virgin gold region, where both dredging and hydraulic mining will flourish. At present this country is entirely unsettled, except by tribes of untutored savages, and mining concessions could be obtained under favorable conditions. The railroad would terminate at the site of the early abandoned mission town of San Borja, at the foot of the Pongo, to which point steamers drawing five feet of water

can ascend even at low-stage in the river. The eastern range is made up of limestones and sandstones, intruded by diorites and other eruptives. Deposits of iron, copper, and lignite exist, and lead is also reported. It will be seen that the proposed railroad offers a field of great promise to the prospector. This enterprise should be watched by enterprising Americans. At the present moment the easiest access is by way of steamer from New York to Iquitos in the Amazonian Department of Loreto; thence by launch to San Borja; from which point travel is more difficult. Another railroad is being surveyed from the vicinity of Cerro de Pasco, partly for the benefit of the copper industry there established, to deep water on the Amazon river-system. If built, this would also stimulate the development of eastern Peru.

The Extra-Lateral Right.

Discussion upon general revision of the mining law at Goldfield next week will occur at a point where expediency has produced a compromise discarding the extra-lateral right. Thus a concrete example will be presented to the delegates to the Mining Congress highly suggestive of benefits to be derived from a return to the old principle of vertical boundaries for mining claims. In July of last year an agreement was reached between the Goldfield Consolidated and the Jumbo Extension, and others, which it may be useful to re-state. The lode in the Mohawk No. 2 claim dips toward the east, and the Wedge fractional claim, lying adjacent on that side was deeded to the Goldfield Consolidated. This company also owns the Lucky Boy and Clermont claims on the east, which are succeeded in that direction by the Polverde. The right to that portion of the vein lying within the vertical side-lines of the Polverde was conceded to the original locators under agreement with the Goldfield Consolidated to mine and treat the ore on joint-account. No extra-lateral rights were acknowledged beyond the east side-line of the Polverde. The Combination Fraction, by agreement with the Goldfield Consolidated, retains everything within its vertical side-lines, the right to the continuation of the vein beyond the Combination Fraction remaining vested in the Goldfield Consolidated through its ownership of the adjoining Jumbo claim. A similar arrangement applied to the Vinegorone, but the rights of the Goldfield Consolidated were recognized as continuing on the dip of the vein beyond the Vinegorone under the Laguna. The consolidation of the Mohawk and the Combination was also in part a result of the perils of legal contest over extra-lateral rights. The January claim, lying on the west side of the Combination No. 1 was purchased by the owners of the Mohawk on the chance that Mohawk orebodies might apex on that ground. The general expectation was, however, that the Combination vein would lead into the Mohawk deposit when followed to that depth. The owners of the Combination evidently relied on that assumption, and a battle royal was anticipated. At that juncture a technical weakness was discovered in the case of the Combination, a single discovery point and monument applying to Combination No. 1 and 2 claims. The application for patent to these claims was thereupon ad-

versed by the other side to the controversy, and the result was a consolidation on terms which in the end have proved exceedingly advantageous for the owners of the Combination. The danger lurking in the extra-lateral right was a powerful lever, but only one lever, in effecting this famous compromise.

A spirit of conciliation likewise led to disregard of the extra-lateral principle at Tonopah, where the West End Consolidated and the McNamara Mining companies adjusted their differences last year by acceptance of vertical side-line limitations. Within six months recognition of the inapplicability of existing law to large masses where nothing exists corresponding to the fissure vein on which the theory of the extra-lateral right is founded, has brought the Nevada Consolidated, the Giroux, and the Cumberland-Ely into harmonious compromise. The extra-lateral right was also discarded at Bisbee, Arizona, for similar reasons. The plain teaching of these examples is that self interest determines whether it be better business policy to fight or to compromise. Abolition of the law as it now stands would provoke new difficulties and lead to a sudden increase in litigation. The rights of a locator under the new law would necessarily be subject to the rights of locators under the old, and the courts would be overwhelmed with suits and petitions for injunction brought by claimants under the Act of 1872. While conceding that the extra-lateral principle has only a limited application, and should not have been introduced, it has stood so long that to set it aside would seem fraught with peril to the economic progress of the mining camps of the West. It seems doubtful whether the immediate influence upon prosperity would not be so detrimental as to offset any ultimate advantage that might accrue.

The American Mining Congress.

The American Mining Congress, which assembles Monday at Goldfield for its twelfth annual session, has, after a somewhat checkered career, become a body of not inconsiderable influence and usefulness. It started, as have many other good things in American mining, in Gilpin county, Colorado. At the height of the agitation for free coinage of silver, certain Gilpin county mining men decided it would be just as well to remind the world of the importance of gold as well as silver. Through their instrumentality a call was issued for a 'Gold Mining Convention'. Alas, however, for human hopes and plans! When the delegates assembled at Denver they hardly awaited organization before introducing and passing the standard free-coinage resolution with which it was then customary to open everything from *kneipes* to prayer-meetings. At this the Gilpin county delegation, sadly ruffled as to feelings, walked sedately down the aisle and out. The Congress, thus deserted by its parents, was left to its fate—a fate which has proved varied and interesting. At first, as the 'International Mining Congress', it was largely an organization used to boom the mining districts in which it successively met. Later, following a narrow escape from capture by the Western Federation of Miners, a group of the more representative members re-organized it as the American Mining Congress.

Certain of the old crowd separated themselves from the organization, and others were separated. A permanent secretary, Mr. J. F. Callbreath, Jr., a lawyer and an owner of mines in Summit county, Colorado, was elected, a paid membership was provided, and new men elected on the Board of Directors.

Under the new organization the Congress, while still small, has grown greatly in character and influence. It has always been a strangely heterogeneous organization, but by that very reason has been the more representative. It has been held together by a small group of men, headed by Mr. J. H. Richards, that has worked hard and unselfishly to keep it alive as a forum for the debate of all public questions relating to mining; a meeting open to all. It may be noted that while many cranks have been allowed to relieve their feelings by introducing resolutions and by making resounding and eloquent speeches, the sober sense of the organization has always prevailed. It is one thing to introduce a resolution and quite another and different thing to get it passed. As a result, the resolutions really mean something, and will repay the careful attention always of any thinking man interested in the mining industry.

The Congress has taken an active part in campaigns against fraudulent mine promotion, in favor of a Federal Bureau of Mines, greater uniformity in mining laws, and a number of equally important movements. It has promoted acquaintance and co-operation among mining men and has been an important influence in educating the public and in formulating public opinion. Yet the organization is far from occupying the position of prominence and influence which its name connotes. It has never become truly national, and while the quality of the membership has constantly improved, it must be frankly recognized that many of the best men connected with mining have constantly stood aloof. If the Congress is to fulfil its mission, and its meetings are to become great annual gatherings where all phases of mining in its relation to the public and to the State and National Government are threshed out, it must secure the support of more of the men prominent in mining, and particularly of the mining engineers. It must have men of national prominence as officers. An excellent suggestion has been made to the effect that Mr. James Douglas be elected president. This would be an eminently fitting selection, as there is no man who stands more exactly for the ideals which the Congress is striving to realize. His election would dignify the Congress, and the establishment of the organization in the larger national confidence would be an especially worthy piece of public service for our eminently useful and public spirited fellow citizen. Mr. J. H. Richards, who now holds the office, has given seven years of singularly disinterested and able service to the work. It is an open secret that he has long wished to retire, and it is hoped that it may be possible for him to do so at this time. Others of the officers will doubtless drop out at the same time. They deserve great credit for the work they have done, but change is inevitable. We believe the American Mining Congress can be immensely useful to the Nation and our good wishes go out to it and its officers.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

S. H. BALL is in Chicago.
H. C. HOOVER is in New York.
F. B. VAN HORN has been in San Francisco.
C. T. DOZIER has gone to Shasta county, California.
OWEN JOHNSON is returning from England to Colorado.
LOUIS FALKENAU has recovered from a severe sickness.
F. LYNWOOD GARRISON has gone to Mexico for a month.
W. F. A. THOMAS has returned to London from Portugal.
HOWARD D. SMITH has sailed from New York for England.
M. K. SHALEB returned from Central Africa September 15.
EDWARD V. D'INVILLIERS has been visiting Pacific Coast cities.

W. R. FELDTMANN left London for West Africa on September 25.

FRANK ANDERSON, of Salt Lake, is in southern Idaho at present.

JUAN FELIX BRANDES has gone to Mexico City and Parral, Mexico.

RUSH M. HESS has returned from Ecuador and is at Reno, Nevada.

S. F. SHAW will be in Costa Rica during October and November.

GEORGE D. REID, of Denver, is in the Seven Devils region of Idaho.

W. H. EMMONS will be at the University of Chicago after October 1.

F. W. BRADLEY has returned to San Francisco from Idaho and Alaska.

O. H. JONES, of the El Tigre mine, Sonora, Mexico, is in Los Angeles.

BENJ. F. TIBBY has opened an office in the Newhouse building, Salt Lake.

E. A. MANNHEIM, of Griffiths, Mannheim & Co., is now at Laveras, in Brazil.

J. M. CALLOW, of Salt Lake, is spending a brief time on the Hawaiian Islands.

CHAS. A. PORTER has located in Salt Lake, having opened an office in the Atlas block.

AUGUST MATTEZ has returned to New York from an extended trip through the West.

CHARLES BUTTERS is expected in New York October 3 on his way from London to San Francisco.

E. S. KING has gone to Wiluna, West Australia, on his appointment as manager for the Gwall Consolidated mine.

J. S. FREE and E. A. Taylor, engineers and mine operators, have opened offices in Salt Lake, Utah, and Pioche, Nevada.

ROBERT HAWXHURST, Jr., has resigned the management of the Poderosa Mining Co., Ltd., and is on his way to London.

NORMAN G. CORSON, formerly of Creede, Colorado, has purchased the assay office and business of J. A. Pack, Boise, Idaho.

WILLIAM WELLS ELMER has resumed practice as a consulting and mining engineer with offices at Coneto, Durango, Mexico.

W. D. B. MOTTER, Jr., has accepted a position as mining engineer for M. A. Hanna & Co., in the Crystal Falls district of Michigan.

JOHN CRAIG, a graduate of the University of California, now manager of the Simmer & Knights Deep of Johannesburg, is in San Francisco.

WILFRED B. WAINWRIGHT, managing director for the Borax Properties, Ltd., of California, has returned to Los Angeles from a trip to New York City.

E. R. BUCKLEY, with the Federal Lead Co., Flat River, Missouri, spent a week in Utah prior to attending the Mining Congress at Goldfield, Nevada.

General Mining News.

ALASKA.

W. H. Heath, of Spokane, has taken eight men to Alaska to develop a group of 20 claims on Willow creek. The company represented by Mr. Heath has been prospecting the claims for two years and has obtained assays as high as \$22,000 per ton from the ore.—The Alaska Mines Exploration Co. has been incorporated in Spokane to develop properties in the Cook Inlet country.

ARIZONA.

COCHISE COUNTY.

A number of the most influential stock holders of the Bunker Hill mine at Tombstone have visited the property lately, and it is understood that operations are to be resumed in the near future.—The north cross-cut from the 120-ft. level of the Doran & Gallagher property opened a body of sulphide ore, picked samples of which assayed 15% copper.

GILA COUNTY.

The Duquesne Mining Co. is erecting a surface plant and living accommodations for the men at its property in Gold gulch, 15 miles from Globe. The company has graded a wagon-road to the Castle Dome road and will commence sinking some time in October. John F. Shaw is in charge of the work.—The new compressor at the Hamilton shaft of the Cactus Development Co. has been started and the drifts are now being run with machine-drills. The company expects to have the Pinto shaft completed to the 541-ft. level by the end of October, when a connection will be made with the Hamilton shaft.—The cross-cut on the 200-ft. level of the vertical shaft at the Live Oak property in the Miami district is in 3% copper ore, and on the 300-ft. level the face is in ore averaging 2.75%. The ore is largely chalcocite.—The Williams shaft at the Iron Cap property of the National Mining Exploration Co. is down 200 ft. The company has installed a compressor and machine-drills and will sink to the 500-ft. level and cross-cut the orebody.—A new compressor and machine-drills have been installed at the shaft of the Superior & Globe Copper Co. It was the intention of the company to cross-cut at the 500-ft. level, but the showing has not been as expected, so the shaft will be sunk another 100 ft. before the lateral work is started.—The Lost Gulch Mines Co. has purchased the machinery for a 10-stamp mill. J. T. Harrington is manager.—The smelter of the Arizona Commercial Copper Co. is nearly complete and will be blown-in in the early part of October.—The Gibson Copper Co. is shipping 10 tons of high-grade ore per day to the Old Dominion smelter. The company has let a contract to W. C. Newlands to timber 60 ft. in the main adit with concrete sets. A short time ago the Copper Queen company tried concrete, but the experiment proved unsuccessful and the concrete was replaced by wood. The Gibson adit is in ground that is hard to hold, so the concrete will receive a good test.

MOHAVE COUNTY.

(Special Correspondence).—The shaft on the Carter mine, situated in Red Gap district, has reached a depth of 145 ft. A new compressor and machine-drills have been installed. These are working satisfactorily.—Reports from Acme say that the adit being run to cut the Red Top mine, on the Gold Road mine, has passed through the hanging-wall and is now in good ore. The adit is in 250 ft., with a vertical depth of 130 ft.—The Mohave Silver Mining Co., whose properties are situated at White Hills, is preparing to do a large amount of work during the remainder of the fall months and ensuing winter. The company owns the McKesson group of mines and claims which have had a large amount of work done on them, paying well for the amount of money expended.—The adit on the Ruth property, situated in Gold Basin district, is being driven at the rate of 4 ft. per day in good milling ore. A steam hoist is in transit. The initial shaft is to be sunk to a depth of 500 feet. Kingman, September 20.

The road to the Golconda mine was badly damaged by

the recent rains, but is now being repaired and the company is preparing to ship 40 tons of ore that averages 50% zinc.—A station has been cut at the 200-ft. level of the Holy Moses mine and a cross-cut started toward the vein.—The first clean-up of the new mill on the Last Chance property at Wallapai Springs resulted in a saving of \$25 per ton. The company expects to install concentrators and a heavier power plant.—S. R. Porter and C. H. Scheu have secured an option on the old Keystone mine in the Wallapai district. A diamond-drill will be installed and the ground thoroughly explored before any extensive underground work is undertaken.

SANTA CRUZ COUNTY.

(Special Correspondence).—Two hundred and sixty tons of ore have been shipped from the Augusta mine, Patagonia district, to the smelter at Globe since the first of the month. Recent rains and cloudbursts have greatly damaged the roads between the mine and railroad, and sometime will elapse before repairs can be made.

Nogales, September 20.

YAVAPAI COUNTY.

(Special Correspondence).—The old Vulture mine, situated 15 miles south of Wickenburg, is opened to the 600-ft. level. On the 450-ft. level a great deal of cross-cutting and driving has been done, and the average of 29 samples of ore from the main vein gave assays of \$9.60 per ton. The mineralized dike at the mine is more than 175 ft. wide, and at the contact of this dike occur lenses of quartz which contains the gold. The mine produced \$16,000,000 from former working.

Phoenix, September 18.

The New England-Arizona Mining Co. has ordered a new hoist for its mine in the Big Bug district. Cross-cutting is now in progress on the 600-ft. level, but as soon as the new hoist can be installed, the shaft will be sunk to the 700, and the vein opened there. J. H. Farrell is manager.—The cross-cut from the 200-ft. level of the Black mountain property, seven miles east of Jerome Junction, is in 115 ft. A slight delay was caused by the breaking of the pump in the shaft. F. A. Reislings is superintendent.—The dam and machinery of the Speck Dredging Co., on Lynk creek, were damaged by the high water caused by a cloudburst.

YUMA COUNTY.

(Special Correspondence).—J. A. Cronkhite, superintendent of the Alvin Development Co., at Salome, reports that the shaft is now down more than 100 ft., with 70 ft. of cross-cutting, in gold and copper ores of good grade.

Yuma, September 27.

CALIFORNIA.

NEVADA COUNTY.

A 2½-ft. vein has been cut on the 900-ft. level of the New York-Grass Valley mine. The mine has been idle for over a year though the pumps have been kept going to keep the mine from flooding. A. P. Wilson, who has been in charge of the property, started a cross-cut to find the vein which had been lost and had only gone a few feet when the quartz was cut.—The Eureka mine, adjoining the Idaho-Maryland property, has been sold by Robert Morrow to McCredie, Tilton and McDonnell, of Oakland, for \$50,000. The mine has been idle for a long time, the owners refusing to accept any terms except a cash sale.

SAN BERNARDINO COUNTY.

(Special Correspondence).—The Needles smelter has suspended operation because of the alleged lack of ore. Stockholders state that the plant will resume at an early date, but there are several rumors concerning the company that indicates the shut-down may be of long duration. It is known that the owners have been anxious to dispose of the plant.—A 32-in. vein of \$83 silver ore has been opened on the Easton group, in the Silver Lake district.—It is reported that a 19-in. shoot of ore, running from \$200 to \$2000 per ton, has been struck at a depth of 600 ft. in the Blue Bucket. A number of small, rich shoots are being opened by cross-cuts in the lower workings.—W. A. Clark, Jr., and associates have decided to resume operations on their holdings near Klienfelder. The 100-ft. shaft has opened

large bodies of ore, with copper predominating. A 50-hp. hoist, compressor, air-drills, etc., have been ordered and the shaft will be sunk to the 1000-ft. level.—The shaft at the California Hills is down 300 ft. Some good ore was recently opened.—The Ibex has been re-organized under the name of the Gold Bank by Mr. Ferguson, of Long Beach. A 5-ft. Huntington mill, with a capacity of 35 tons per day, has been purchased, and work will be resumed at an early date.—Clausen & Ware have sold their holdings at Gold Flat to Pasadena capitalists for \$20,000. The group has been opened by a 125-ft. shaft. Development will be started immediately with C. M. Lamb in charge of the work.—The Leiser-Ray Mining Co. has installed a 50-ton crushing and leaching plant at the Homer mine.—J. F. Main has opened a body of ore running \$5 to \$500 per ton in gold and tungsten on his Signal property.—A large deposit of China clay has been discovered near Klienfelder by D. E. De Lape. A force of men will be put to work at once.—The Lucile Gold & Copper Mining Co. has opened a large vein of milling ore. It has been exposed for 300 ft., and averages \$8 per ton. Orders have been placed for a small stamp-mill.—Davis & Helgersen have bonded the Washington claim.—A 300-ft. deposit of ore, said to run 4% copper and \$10 gold, has been opened on the surface for a considerable distance by Dillon, Howard & Kelly at Lone Willow spring.—A high-grade body of silver ore has been opened in the Iris claim. Shipping will commence within a few weeks.—The Koch group reports the uncovering of a small vein assaying 22% copper and \$60 gold.—The Custom mill, at Victorville, has resumed operations and is treating 15 tons of ore per day.—At the Wild Rose the shaft is down 75 ft. on a vein of high-grade ore.—Two large veins, running from \$8 to \$25 per ton, have been opened on the Guarantee Mining & Development group. The main shaft is down 150 ft., and the 5-stamp mill is running steadily.—The Morse-Kayser Mining Co. has completed a 5-stamp mill at its property near Victorville.—The Big Chief Mining Co. has secured a bond on the Jumbo, Good Luck, Clapper, Clapper No. 2, and Clapper No. 3 mining claims at Hart. The bond runs for one year and is for \$75,000 to be made in monthly payments, the final one being \$40,250. A compressor and machine-drills will be installed at once and a mill built on the property at a later date.

San Bernardino, September 20.

SHASTA COUNTY.

The Delta Consolidated Gold Mining Co. filed suit against the Inca Treasure Gold Mining Co., charging M. E. Dittmar, Sherman T. White, Edward Sanders and Martin Hveem with misuse of their powers as officers in purchasing the Pioneer Black Oak mines, which they knew were worthless at the time of the purchase. The company is erecting ore-bins at Delta and has commenced shipping ore.—The Mammoth Copper Mining Co. is to resume the treatment of flue-dust in its Kennett smelter. For the past six months this has been sent to the Balaklala plant at Coram. The fine is shipped to the Peyton Chemical Co., at Martinez.—Over 200 members enrolled at a recent meeting of the Shasta County Farmers' Protective Association, and voted to allow the smelting companies until November 1 to take some definite action in reducing the smelter fume.—It appears that the dredge of the United States Gold Dredging Co., on Middle creek, did not sink because of the failure of the hull, but because the extra machinery caused the dredge to lie so deep that water came into the seams which were dried out. The hull gradually filled up until the water came over the deck and poured in the open hatches. Curiously this condition was not discovered until the dredge started to sink. The dredge is now being pumped out and it is found that but small damage has been done to the hull. The remodelled dredge is fitted with standard Risdon machinery, and the company officials are sanguine as to future prospects.

SIERRA COUNTY.

A drift has been run 140 ft. on the vein at the Twenty-One mine near Alleghany. The ore contains considerable quantities of sulphides as well as free gold.—A recent

test of the gravel at the Omega mine, near Forest, resulted in a clean-up of \$10 per car.—E. J. Morgan, of Nevada City, has secured a bond on the General Sherman property near Alleghany.—The Voyle Brothers are to install a 3-stamp mill, driven by a gasoline engine, at the Oakland mine.

SISKIYOU COUNTY.

On a recent run of the Kradle and Newcome mill at Oro Fino the clean-up amounted to \$20 per ton. There is considerable ore stored on the dump for another run.—The clean-up on a run of 15 tons of ore from the Oom Paul mine of McChoncie & Kirk resulted in a 45-oz. gold-bar.—New pumps have been installed and work resumed at the Shelba mine which was recently closed down on account of the heavy flow of water.—Owing to the lack of water the Gardener & Weed mine, in Quartz valley, has been closed down for the season. The last clean-up was excellent and the mine will be put in order to resume operations with the first rains of the season.

TRINITY COUNTY.

At the La Grange hydraulic mine the company is building additional living quarters for the men and repairing the ditch for the fall work.—The company operating the Headlight mine, near Carrville, has purchased the Jumper & Morris sawmill and moved it to the property. The company is building a new 40-stamp mill and chlorination plant. The vein is 40 ft. wide and runs between \$4 and \$5 per ton.

TUOLUMNE COUNTY.

The vein recently discovered by W. C. Fuller on Knights creek, north of Sonora, has been stripped for 50 ft. showing free gold the entire distance.—The clean-up on a trial run of 50 tons from the Knox & Boyle property amounted to \$2500.—The mill at the Harvard mine is again in operation.—The winze at the Hancock is down 50 ft. on a 20-in. vein that assays \$25 per ton.—The Rough and Ready placer mine, at Mountain Pass, has been bonded and will be operated this winter.—A car and rails have been shipped to the Jumper mine, near Jamestown, and it is understood that work will be resumed at this property in the near future.—The clean-up at the Ida Kline amounted to \$1500 last week.—It is the intention of the Atlas Mining Co. to erect a mill on its mine on Jackass hill. Previous to this the ore has been crushed in the Street mill in Tuttle-town.—The mill at the Yrma mine is to crush 2000 tons of ore to test its value.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—A rich find has just been made at the Conqueror mine, situated on Covode mountain. The discovery was made 900 ft. from the entrance of the adit. A streak of smelting ore that is 2 ft. wide has been cut. The ore assays 5 oz. gold per ton, and the ground is being opened preparatory to stoping. The 50-ton mill is running night and day and a heavy tonnage of concentrate shipped. W. S. Pryor is manager.—A 8-in. streak of lead ore was uncovered on the Homestake property that assays \$44 per ton gold, silver, lead and copper. The adit has been advanced over 400 ft., and now that the Homestake vein has been cut, drifts will be started east and west. Jos. Trudeau is manager.—David Kennedy, manager of the Centennial mine, returned last week from Boston, where he had been in consultation with the directors of the company regarding future development. It is stated that work will be put under way some time during the present month in the construction of the new stamp-mill which is to have a capacity of 50 tons per day. In the meantime a force of men is being employed in blocking out the ore-reserves in order that ample material may be available to insure a steady run.—A streak of ore 8 in. wide has been cut in the heading of the Capital adit at a depth of 2200 ft. The ore assays 5 oz. gold and 30 oz. silver to the ton with 7% copper. W. M. Cooper is manager.—H. A. Shipman visited the property of the Golden Glory T. & M. Co. last week and after examination instructed J. L. Young, the

superintendent, to proceed with the advance of the adit, which is now in 600 ft. The first vein to be reached is the extension of the Bellevue-Hudson.—Work will be started shortly at the Kelly adit on Democrat mountain. Advice received from D. H. O. Marcy, of Boston, are to the effect that the financial end has been provided for and that the big bore, now in 2800 ft., will be advanced at least 5000 ft. A number of contracts have been signed by owners of mines which lie along the course of the adit. B. F. Kelly, the originator of the plan, will serve as the manager for the new company.—The Newhouse adit was advanced during the month of August 338 ft., making the total distance driven 19,890 ft.—The Hedenburg mine, situated in Spring gulch, is being re-opened. Drifts have been started on a streak of smelting ore that is 10 in. wide, and assays \$36 per ton gold and silver.—Work on a large scale was put under way last week on the Rockford adit, situated on Donaldson mountain. The drifts on the Donaldson and Magnolia veins are also to be extended and the ore is being blocked out preparatory to the blowing in of the pyritic smelter at Golden, which was recently purchased by the North American Mines & Smelter Co. The old Kilton sampler is now undergoing repairs and will be put into commission shortly. A number of operators have signified their intention of shipping to this plant.

Georgetown, September 20.

OURAY COUNTY.

The east drift on the Klondike vein from the Atlas workings opened a rich shoot of ruby silver with a considerable copper content.—The raise from the lower adit of the Thistledown property is within 200 ft. of the old workings. The work has been in ore the entire distance and the shoot is thought to be the one worked in former years.—The Ouray Commercial Club shipped a large number of 25-lb. samples of Ouray county ores to the Colorado Interstate fair which was held in Denver.—The new hoist is running at the Legal Tender mine and the work of sinking to the contact started.—At the San Antonio mine, on Red mountain, the Carbon Lake shaft has been sunk 200 ft. on a body of copper ore, and the Koehler adit driven to cut the vein 350 ft. below the bottom of the shaft.—A large body of lead-copper-silver ore has been opened at the Senator Beck mine by E. C. Mattes.

SUMMIT COUNTY.

The Summit County Power Co. completed the installation of an electric plant at the Pennsylvania mine and both mine and mill will be operated by electricity. W. B. Le Wald is in charge of the work.—The main adit at the King Solomon property is in over 3000 ft., and should open several veins in a short distance. On the No. 2 vein the east drift is following a streak of copper ore and on No. 4 the raise is in ore that assays \$42 per ton.

TELLER COUNTY.

C. E. Meisee has secured an 18 months' lease on the Hannah Britt mine from the United Gold Mines Co. The mine contains large low-grade orebodies, the product from which will be treated at the Wild Horse and Golden Cycle mills.—The Trilby Mines Co. has started its new mill on ore from the Trilby and Ben Harrison mines. The mill is operated by electric power and has a capacity of 75 tons per day. The management will continue to ship the high-grade ore but all that mined from the large oxidized orebodies will be treated in the mill to which a cyanide annex will be added shortly. The annual meeting of the stockholders will be held in Cripple Creek in October.—The Atlantic Mines Corporation has leased the Santa Rita mine, on Squaw mountain, to Daniel Mahoney. The mine is equipped with a good plant and work will be started at once on the main Santa Rita vein north of the shaft.—S. Sindlinger has installed an electric hoist at the Lonaconing shaft which he is operating under lease from the El Paso company. A new shoot has been opened on the Lonaconing vein that assays \$40 per ton.—The dump of the Old Gold Mines Co., on Bacon hill, has been leased and a rotary washer installed. The ore will be washed and screened and the fine shipped to one of the valley plants.

—The Clements Mining & Leasing Co. is installing a new hoist and power plant at the shaft on the property of the Gold Sovereign Mining & Tunnel Co., on Bull hill, which it is operating under lease.

IDAHO.

ADA COUNTY.

The Whitman mine, at Pearl, in charge of Wm. H. Hutchings, is mining and milling about 20 tons of ore per day, and shipping concentrate.

ELMORE COUNTY.

(Special Correspondence).—The mine and mill of the Bagdad-Chase Mining Co., in the Atlanta district, are in operation, under the superintendency of F. W. Bewely. The mill has 40 stamps, Frue and Johnson vanners, two Allis-Chalmers tube-mills, a roasting-furnace and cyanide plant, treating 150 tons of ore per day. The pulp passes from the mortars through 20-mesh screens, over amalgamating plates on which a 40% extraction is made. The plate-tailing, containing iron and arsenopyrite that contains gold, is then classified and concentrated, the coarser concentrate being re-ground to 100-mesh in the tube-mills. The tube-mill product and the finer vanner concentrate are then run together and given an oxidizing roast, after which they are cyanided, the result being an extraction of 90% of the gold in the concentrate, or 50% of the value of the ore. The ore runs \$5 gold per ton, and 50 to 75c. silver. It is stated that the cost of mining and milling is \$2.44 per ton. The ore occurs in a wide lode, in granite, and the walls are not well defined. The mining is done by hand-drilling, the ore being conveyed to the mill by an aerial tramway. The mill machinery is operated by electric power, generated at the company's plant on the Boise river. A passable wagon road has been made from Boise, up the river of that name, to Atlanta, a distance of about 85 miles, though most of the hauling to the camp is from Mountain Home via Pine and Rocky Bar.

Atlanta, September 18.

IDAHO COUNTY.

The contract for driving 100 ft. on the vein at the Gold Bullion mine has been completed and another contract will be let as the drift was not driven far enough to tap the ore-shoot.—Machinery for the dredges on Elk creek and the American river is being freighted through Elk City. It is expected that the dredging will be started about the middle of October.—Arrangements have been made for further development work at the property of the Umatilla Mining Co. Orrin Lamb is superintendent.—At the Buster mine the cross-cut from No. 2 adit opened several stringers of ore.—The engineers of the Northern Pacific railroad are surveying a line from Stites through Harpster to Elk City.

MONTANA.

MISSOULA COUNTY.

A drift is being driven on the vein of the True Fissure Mining Co., near Saltese, that will give 1000 ft. of backs. Over \$35,000 has been spent on the property and a large amount of ore blocked out. John Lefevre is manager.—There are 75 men working in the Success mine and mill, near Nine Mile, and the company expects to increase the force to 100 in a short time. Regular shipments of concentrate are being forwarded to the smelter and when the force is increased the company will ship 1200 tons per month.—The adit of the Iron Mountain Mining Co., near Superior, cut a 6-ft. vein of zinc ore. A stope has been opened and the company is preparing to ship to the reduction works at Columbus. Over \$500,000 dividends have been paid from shipments of lead-silver ore from a parallel vein.

SILVER BOW COUNTY.

(Special Correspondence).—The steel ore bins of the Butte-Ballaklava Copper Co. have been completed and the company will begin regular shipments of ore during the coming week. The body of bornite, 35% copper ore, on the 1300-ft. level, still continues in the drift and has now been blocked out for 120 ft., widening and showing indica-

tions of continuing to great length and depth. About the first of October the company will begin raising the third compartment of the shaft from the 500-ft. level to the surface. Until that compartment is completed the production of ore will necessarily be limited, as raising will interfere somewhat with mining, but there will be no cessation and about 100 tons per day will be hoisted. When the shaft is completed the output will be materially increased, the mine being in condition to yield at least 300 tons per day.—It is expected that work on the new zinc concentrator of the Butte & Superior company will begin shortly and that it will be completed in about three months. It will have a capacity of 300 tons per day to start with, and if it proves successful, it will be enlarged. The owner of the zinc process will erect the mill and purchase the ore from the Butte & Superior company, but giving the company a contract or option to purchase the mill if it works all right. The Butte & Superior had been shipping some of its ore to the concentrator at the Butte Reduction Works, owned by W. A. Clark, but after Clark's Elm Orlu mine became able to supply all the ore the concentrator could handle, the Butte & Superior was shut off. As the Butte & Superior concentrate is of an especially high-grade and much sought by zinc smelters, the company determined to have a concentrator for its exclusive use built at the Black-rock mine.

Butte, Montana, September 20.

NEVADA.

CHURCHILL COUNTY.

(Special Correspondence).—The main shaft at the Nevada Hills is down 450 ft., and a drift will be run from this point to intersect an orebody that was recently cut by the

from its own holdings.—Rawhide at present boasts of 19 shipping properties and it is expected to add three to the list within a short time. Nearly all the active properties are arranging to increase their production.—At the Marigold a 5-ft. vein of milling ore has been opened on the 165-ft. level.—The Little Four lease is trenching on the surface to locate several veins supposed to traverse its ground. The development of the main orebody is steadily progressing.—The Lawyers lease is arranging to drive a cross-cut from the 125-ft. point to intersect a vein that outcrops east of the main orebody.—A 3-ft. vein of high-grade ore has been cut on the Alexander, and is being sacked for shipment as it is broken.—The hoist has been placed in commission at the Bridges-Daniels lease, on Bethania, and sinking has been resumed.—The Mint lease is in a body of good ore.—At Kearns No. 2, the management has increased the working force, and has arranged for a steady production. Conditions in the lower levels are satisfactory.—Owing to lack of adequate milling facilities many properties have been compelled to devote their attention to their high-grade deposits almost exclusively. The custom mills have been almost entirely taken over by the Coalition, Queen Victor or other strong companies, and many small producers are at a loss to market their low-grade production.

Rawhide, September 17.

(Special Correspondence).—The operation of the Florence mill at increased capacity with its new machinery has been delayed by the failure to arrive of two pumps which are necessary for the completion of the plans. Temporary pumps are now being installed by Willis Lawrence, manager, and the mill will be operating with a capacity of at least 160 tons of ore daily in a short time. As the result of experiments carried on for some time, amalgamation has been superseded to a large extent by the use of carpets in saving the gold, and this method has been found successful as well as effecting a material reduction in expense. In August the mill treated 3600 tons of ore, with a recovery of over \$87,000, and it is expected that a better grade of ore will be treated than the \$25 grade that has been sent to the mill in the past. The main tonnage comes from the Little-Florence shaft, whence it is carried to the mill-bins by aerial tramway.

Goldfield, September 21.

LINCOLN COUNTY.

Free & Taylor, of Pioche and Salt Lake, have under development the Bristol-Avon, Kismet-Bristol, and Pioche King properties in Pioche district.

NYE COUNTY.

(Special Correspondence).—Holland, Malley and associates are at work on the 100, 200 and 300-ft. levels of their lease on the Stone Cabin claim of the Jim Butler.—The station on the 1500-ft. level of the main shaft, at the Tonopah of Nevada, is being rapidly completed, and important work in the lower workings will be conducted from this point.—The machinery and material for the Tonopah Extension mill is arriving rapidly and the force of men working on the buildings has been increased.—Excellent ore is being opened in the 200, 275 and 300-ft. levels of the MacNamara. On the 300 the vein is 4 ft. wide and is of good milling grade throughout the 60 ft. exposed. On the 275-ft. level the vein is 3 ft. wide.—Fourteen lessees are working at Ellendale and several report a good grade ore.—On the Clifford-Nay original holdings the adit that was being driven to cut the vein has been abandoned and a shaft will be sunk to the pay-shoot. The adit was driven 120 ft. with no indication of the orebody.—The monthly clean-up of the Shoshone mill has been completed and is estimated to be about \$45,000. Practically all the ore is coming from the glory hole. Extensive explorations are about to commence from the 700-ft. level.—The creditors of the L. M. Sullivan Trust Co. are arranging to perfect details for the

Florence-Goldfield Mill.

winze from the 350-ft. level. The winze is 60 ft. deep, and samples from the shoot assayed \$600 gold and 1000 oz. silver per ton. W. H. Webber is manager.—It is reported that work will be commenced at the Eagle's Nest at an early date.—Reports from the Fairview Eagle state that good grade ore is being opened.—The Nevada Wonder is said to have secured the Horse creek water rights, and will probably shortly arrange for the erection of a milling plant.—The Fairview and Wonder districts continue quiet, but indications are promising for improved conditions before the end of the year.

Fairview, September 18.

ESMERALDA COUNTY.

(Special Correspondence).—Eight stopes are open on the Victor and it is estimated that sufficient ore is in sight to keep the mill in operation for two years. Funds have been raised to double the capacity of the plant. All custom ore for September has been refused, and no more will be accepted for some time to come.—E. W. King, of the Queens, is planning to increase the capacity of the National mill, of which control was recently acquired by the Queens people. This company is arranging to mill 300 tons per day

operation of the Jumping Jack, Stray Dog, and Indian Camp mines at Manhattan on a large scale. These properties are now being worked under a five-year lease by the Manhattan War Eagle Mining & Milling Co. At the Stray Dog, the mill is being overhauled and will be placed in first-class condition. It is reported that a 12-ft. vein of ore running \$12 to \$15 per ton is exposed at the bottom of the 250-ft. shaft. The Mineral Hill Co. has installed a gasoline hoist and will sink to the 300-ft. level. From this point cross-cuts will be run to cut the vein opened at the 225-ft. point.—Placer mining throughout the Manhattan district continues to yield good returns. Work is mainly centered on the main gulch, but the lateral deposit is also receiving attention.—The Johnnie Mining & Milling Co. has purchased the Battery group, on which a vein of \$14 ore was recently opened, for \$6000.—The shaft at the Penobscot is down 50 ft., and has cut several stringers running \$10 per ton. M. Rathburn is manager.

Tonopah, September 18.

STOREY COUNTY.

(Special Correspondence).—It is rumored that the Gould & Curry Co. will shortly resume work on the Sutro Tunnel

The Counties of Nevada.

level. The north lateral is in good condition and the free admittance of fresh, cool air will greatly facilitate the projected work.—The Brunswick lode is attracting much attention, following the rich strike made some time ago in the Baker mine. The Consolidated Virginia has leased its holdings on the lode to George Wright, Benjamin Kelly and William Way. Work has been commenced and it is expected to strike the vein open on the Baker.—The lessees on the Conlan have the shaft down 20 ft. and are working steadily.—The Union claim has commenced work with a small force of men.—On the Comstock-Merrimac two shoots of high-grade ore are being opened. Assays are said to run from \$75 to \$300 per ton.

Virginia City, September 20.

WHITE PINE COUNTY.

(Special Correspondence).—The Butte & Ely Copper Mining Co. has passed to the control of Thomas F. Cole

and John D. Ryan, presumably, for the Giroux Consolidated company. The option on a controlling interest in the stock was taken up last Saturday. It included 229,175 shares of treasury stock and 10,000 shares of individual stock, out of a total issue of 500,000 shares. The option was at the par value of \$1 per share. In order to obtain control it was first required that the individual shareholders contribute 10% of their holdings to the optioners, but the Cole-Ryan interests afterward reduced that to a lump amount of 10,000 shares, which was quickly made up. The holders of the option made large purchases of the stock on the open market under \$2 per share, and it is surmised that they now own probably 300,000 shares. The \$229,175 to be paid for the treasury stock will, of course, go into the treasury of the company, and the new owners really paid for the property only what was paid for the 10,000 shares of individual stock, and such stock as was purchased on the open market. During the three months in which the option ran, the Cole-Ryan people thoroughly explored the Butte-Ely ground, and satisfied themselves as to the value of the property. The ground, consisting of 12 claims and comprising 210 acres, lies between the property of the Giroux Consolidated and the Ely Central, and below the Nevada Consolidated. The Butte & Ely also owns a big water right, the most valuable in the district, and said to be worth really more than the mining property itself, and of which the Giroux company is greatly in need. The water right is capable of furnishing 2,000,000 gallons daily. The new owners of Butte & Ely have elected the following directors, all close personal friends and associates of John D. Ryan: William D. Thornton, Arthur C. Carson, A. L. Longley, J. C. Adams, and L. O. Evans. Mr. Thornton, who is president of the Greene Consolidated company, was elected president of the Butte & Ely; J. C. Adams, vice-president; A. C. Carson, treasurer, and Roy S. Alley, private secretary of John D. Ryan, was elected secretary of the company. It is the general impression that the Ryan and Cole interests are acquiring control of other companies in the Ely district, and that eventually their holdings there will be consolidated in a new company or under the Giroux Consolidated.

At a depth of 865 ft. the shaft of the Boston Ely cut an intrusive formation with considerable copper carbonate on the contact, the shaft to that point being entirely in limestone. The ground through which the company is now sinking is the characteristic capping and it is expected to cut commercial ore below this, as it is similar to that cut in the Alpha shaft of the Giroux company before the ore was opened. Edward W. Ralph is superintendent.

Ely, September 20.

UTAH.

EMERY COUNTY.

The Southern Utah railroad is building an extension from its present terminus at Miller Creek to the holdings of the Castle Valley Coal Co., on Cedar creek. This will open a large territory and the officials of the coal company claim that they will be in a position to ship 1000 tons of coal per day. Recent analyses gave 93% carbon, and volatile matter, and 7% ash.

JUAB COUNTY.

The Swansea mine, at Silver City, has been closed down recently. The management stated that there was no market for the ore, and that the expense of pumping was too heavy to keep up development longer. It was understood that there is a project on foot to drive a drainage adit 500 ft. below the mouth of the shaft.—At the Centennial-Eureka a deep drainage adit is to be driven through the ground of the McKinley Mining Co. to drain the Eureka shaft. C. E. Allen is manager.—The shaft at the Tintic Humboldt is down 50 ft. in a lead-iron-gold ore. John Taylor is superintendent.—The old Eureka Hill mill, at Eureka, is being dismantled and the machinery sold. It was erected in 1893 and put the Eureka Mining Co. in the ranks of the dividend payers, being one of the largest pan-mills in the world.—The Eureka City Mining Co. has obtained the signatures of nearly all the property holders in Eureka to an agreement allowing the company to prospect the ground beneath the town.

Special Correspondence.

MEXICO.

Necaxa Power-Plant — Totolapam, Oaxaca. — New Mill Planned. — Flood Losses at Monterey.

The arrival of F. S. Pearson at Mexico City is likely to mark some further development in the numerous large enterprises in which he is interested in this country. James D. Schuyler, the well known hydraulic engineer, who has been acting as consulting engineer during the design and construction of the dam and hydro-electric power plant at Necaxa, is also on a visit to Mexico. Mr. Pearson and Mr. Schuyler have just completed a tour of inspection of the plant at Necaxa, and Mr. Pearson states that over five millions will be spent in further improvements and in additional reservoirs, which will bring the total storage capacity up to 190 million cubic meters of water, and the capacity will eventually be increased to 100,000-hp. The repairs in the main hydraulic-fill dam are now complete, so that they have caught up to the position that they occupied before the accident of a few months ago, and the dam will

An Old Stamp-Mill in Oaxaca.

be completely finished by next March. The reserve of water actually retained by the dam at present is approximately 8,000,000 cubic meters, and the amount is steadily being augmented. The work now in progress on the power-plant will increase the capacity by a further 16,000 hp. by the end of the year, bringing the total capacity at that date up to 66,000, and by the end of July of next year the total capacity will be 100,000, as already stated. The auxiliary steam plant in the City of Mexico will probably be closed at the beginning of the year, and will only be held in readiness in case of emergency.

Several discoveries in the district of Totolapam, State of Oaxaca, have attracted prospectors, amongst others two well known mining men from the Taviche camp, D. C. Kling and J. S. Mills, are preparing for an extensive prospecting tour to cover several months. The San Francisco mine, in the State of Oaxaca, has sent a quantity of ore to the United States for test treatment. It is the intention of the company to erect a mill of 100 tons capacity, which will be one of the largest in the State.

As the lines of communication that were blocked by the flood in northeastern Mexico are opened up, and news comes in from the more remote points, the already appalling estimates of the loss of life and property have to be increased; some estimates place the total loss of life in the valley at 8900, and the property-loss, including that in the town of Monterey, the railroads, and haciendas and small farmers, at \$50,000,000 to \$60,000,000.

The Rio de Plata company, which is in the Guazapares district, has its new hydro-electric power-plant in operation, and the mill working to full capacity, the shipments for the first half of August amounting to 50 tons of 2000-oz. (silver) concentrate, besides the bullion from the cyanide plant, of which there has not yet been a shipment for August. At the Dolores mine, in the Guerrero district of Chihuahua, a rich surface strike was recently made, running up to several thousand dollars per ton, and though it has not yet been proved, it gives promise of being of considerable extent. From the developed workings, however, the company is taking something in excess of 100 tons per day, or, to be exact, in the last fiscal quarter-year there were produced 9447 tons of a total value of \$246,867, the expense of production amounted to \$155,135, so that there was a profit of \$91,732, or a little over \$30,000 per month.

LONDON.

Lords' Dues.—Carn Brea & Tincroft.

The question of lords' dues has cropped up once more in Cornwall. It is a matter which is always with us and probably always will be unless some super-eminent mining engineer, who is also a commander of large supplies of money, can persuade the landlords to accept co-partnership without obtruding their personalities too much when new schemes for development are being arranged. Lord's dues and the influence of the lord on the methods of working the mines, are relics of the days of shallow hand-to-mouth mining. When old mines are re-opened in Cornwall the same old methods are adopted in most cases by both the miner and the landlord. Though the prosperity of the country in general; and therefore the pocket of the landlord, depends so much on the successful working of the mines, in few cases does the landlord meet the circumstances in a modern spirit. Some of the landlords are generous, but that is not enough. It lies in their power to remodel the whole system of mining without waiting for the hypothetical influential engineer that I have spoken of. Take a case in point. At the Carn Brea & Tincroft, part of the ground belongs to Lord Clifden and the remainder to Mr. Bassett. Lord Clifden has been practically the mainstay of the mine for years. He has bought shares in order to provide capital, and he has foregone his royalties. According to an old lease the dues were arranged on a scale of one-twenty-sixth of the gross value of the output when black tin was £55 per ton, or one-fortieth when over that price. During the first year Lord Clifden paid £80 monthly toward pumping, and on the formation of the present company, in 1900, he subscribed £12,000. When the period of depression was on, he received no royalties at all, that is, during the years 1896 to 1906, though within that time some £200,000 was received from the sale of tin. It was not until 1906, when the price of tin went up, that any royalty was paid. Since the formation of the present company, in 1900, the finances have only just been kept together, at first losses being the rule, and more recently profits being made during the high prices for the metal. The net profit for the whole nine years has been only £800, and during the last three years, during which royalties have been paid, the lords' dues amounted to £9307. It will be seen, therefore, that while the company just managed to keep in existence, the landlord obtained £9307 out of his mineral rights. But he has so far been out of pocket on the whole transaction, for it cannot be said that his investment of £12,000 in the shares of the company has been profitable.

In contrast with this landlord many examples could be given of unsympathetic ones, but that is not the point I wish to argue. Similarly, it is useless to approach landlords and ask for indulgence. These things should be done on strictly business lines. The future of Cornwall depends on the introduction of an entirely new system of mining.

New shafts, geological investigations, large expenditure on equipment, and developments on a modern scale are required, but they cannot be carried out when the landlord's interest is different from that of the financier or the shareholder. The royalty on output should be merged into a proportion of the profit during the life of the company; the landlord should be chairman of the company, and he should have the power to appoint an experienced mining man as a co-director. By 'experienced mining man' I mean not a Cornish bal captain, but an engineer with modern ideas and experience in metalliferous mining gained in more than one part of the world.

SALT LAKE, UTAH.

Profits in Zinc Ore. — Tintic Smelter may Continue. — Red Warrior Ready to Ship.—Consolidated Mercur's report.

Utah mine owners are giving much attention to the zinc industry, since the tariff placed upon the product went into effect. At Park City the Grasselli Chemical Co. is treating the zinc product from the Daly-Judge mine in the new plant recently constructed. Fifty tons per day is being concentrated, from which the mining company is making a net profit of \$10,000 per month. Some alterations have been made in the method of treatment which effects a saving of 8%, and the mill is to be increased to a capacity of 150 tons per day. The United States S. R. & M. Co. has just installed a Huff electrostatic separator in its concentrating plant at West Jordan, and a trial run on the ores from the company's Bingham mines has resulted in securing a 55% zinc concentrate. By this process the company expects to make a saving of zinc which has hitherto been a total loss of \$500 to \$600 per month. George W. Helntz, manager for the company, explains that by this process the lead-silver is segregated from the zinc. The zinc carries off the gold in the slag and both were a total loss, as it was found unprofitable to ship this slag to the Eastern refinery and have it treated.

Since the first announcement that the Tintic smelting plant would close on October 1, Jesse Knight says that a number of shippers have held out inducements for him to continue. The difficulty has been that the ores treated carried too high a percentage of silica, and the company found it impossible to get the character of ores desired to mix with the Tintic product. Some of the Ploche mine owners are anxious to have this smelter continue, and are now making an effort to get regular contracts with a number of mine owners to supply the Tintic furnaces with the ores desired. The Prince Consolidated, of Ploche, has been shipping ore regularly to Tintic, and now that the consolidation of the Ohio-Kentucky with the Nevada-Utah Mines & Smelter Co. has been arranged, another large producer will soon be ready to ship to Tintic. Beaver county mine owners are anxious to send their ores to Tintic, as a much lower rate both for transportation and treatment could be obtained.

W. J. Merritt has again become manager of the Warrior mine in Beaver county. After Merritt had proved the presence of large orebodies in this property some of the Duluth, Minnesota, people obtained control and changed the management. The new owners were not familiar with the country and were not successful in their explorations. It was decided a few days ago to again employ Merritt, and immediately upon taking charge he showed the owners the trend of the veins which have been opened to a depth of 400 ft. The ore is a 'sand carbonate', and has been uncovered on four levels. Shipments will begin at once, and it will be the largest producer in that camp within 30 days.

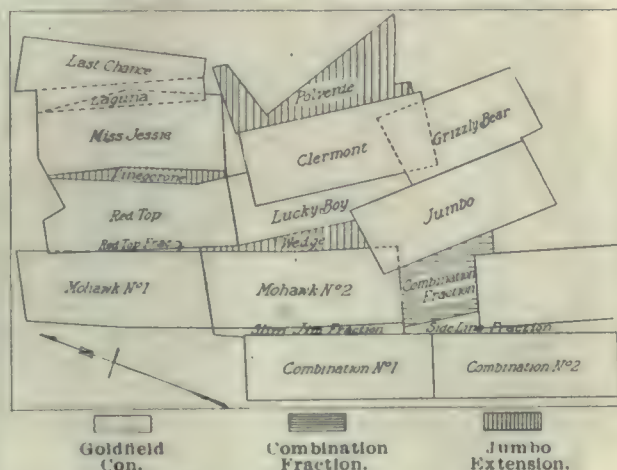

Out of a total production of gold during the year, amounting to \$774,417, the Consolidated Mercur Gold Mines were only able to show a profit of \$33,905. From July to December 1908, inclusive, the profits were \$30,324. From January to June they were only \$3680. During the last six months of the year a much lower grade of ore was milled, and George H. Dern, the general manager, says they found it a hard matter to come out even. The company has a balance account of \$75,029. The average value of the ore being treated is \$3.58, and the loss is 88c. per ton. They have a

large tonnage of ore blocked out, and development is to be continued for the present to ascertain if it be possible to get a better grade of ore, in order that there may be some profit to the shareholders. A slime-plant was built during the year.

GOLDFIELD, NEVADA.

Proposed Assessable Stock.—Combination Fraction.—Clermont Development.—Consolidated Dividends.—Florence Mill Additions.—Tailing Disposal.—Goldfield Daisy.—Goldfield Belmont. Silver Pick

The camp of Goldfield is just six years old and its gross production of gold is conservatively estimated at above \$30,000,000. This year's yield will approximate \$15,000,000 according to the most reliable figures available, and the renewal of activity in leasing operations may enhance this materially. Several important discoveries have been made recently, not only upon the ground of the Consolidated, Florence and Combination Fraction, but in territory that has heretofore been unexplored or unproductive. In common with other high-grade gold camps the development of Goldfield has come about largely through the operations of lessees and an encouraging sign of the times is to be found in the increasing demand for leases on inside territory, particularly upon the Wingfield holdings. This revival of activity has already resulted in the disclosure of good orebodies in ground which has been considered barren. Many of the so-called inside properties have remained idle for many months, the companies having been unable to realize

Map Showing Situation of Principal Mines.

funds for development, and the proposal to re-incorporate some of these concerns upon a basis similar to that of the Comstock companies, making the stock assessable, is being agitated and will be the subject of an address to be made before the members of the American Mining Congress by Herman Zadig, of San Francisco.

The orebody recently opened in the Combination Fraction at both the 300 and 425-ft. levels has been developed to a point which proves its great magnitude and value. The ore-shoot was entered in driving to the south and in the territory embraced in the former Little-Florence lease which was forfeited a month ago. The vein was penetrated by the lessees at a point where the ore was of low-grade and a raise in the vein failed to discover ore of paying quality, but the new shoot, containing seams of exceedingly rich ore in the centre and on the footwall, was missed by only a few feet. The ore-shoot at the lower level is from 8 to 10 ft. wide, and the mine assays for the entire width, have been running from \$120 to \$160 per ton. From an average of \$25 per ton the grade of ore treated by the Fraction company at the Nevada-Goldfield mill of 20-stamps has been increased to above \$40 and for the next month may be expected to average even more than this figure. Another vein carrying \$25 ore, of equal width and nearly parallel with the rich lead, has been opened. At the 600-ft. level of the Mohawk mine, and 300 ft. east of the main shaft, an orebody has been exposed that rivals in richness the best de-

posits found by the early lessees. The cross-cut entered the vein through the hanging wall and has not yet reached the foot wall. The ore is seamed with streaks of high-grade in which the free gold is visible. This discovery was entirely unexpected and it is not yet determined what vein this is, but it is thought to be an off-shoot from one of the veins exposed at the upper levels of the mine. The ore is heavily impregnated with sulphides and the average value thus far, as shown by mine sampling, is far above the best milling grade throughout the orebody. The cross-cut at the 730-ft. level from the Clermont shaft is still in ore, having remained in a continuous shoot of rich material for over 200 ft., the vein turning to the west and following the direct line of this level as originally planned to run for the Mohawk vein.

The northwest lateral from the 600-ft. station of the Clermont shaft has penetrated the hanging wall of the vein on the Lucky Boy at a point farther south and east than was anticipated, and it is apparent that the vein assumes a dip more nearly horizontal at this depth than nearer the surface. Above this point a heavy production is being made

the mills of the Consolidated and Florence. The principal production of the Consolidated is still from the Mohawk mine, from which the output is approximately 10,000 tons monthly, while the Combination, including the great Hampton stope and the Red Top, are yielding nearly 6000 tons every 30 days. Stopping is in progress on the fourth level on the southern end of the Combination No. 1, and the Combination No. 2, near the Florence boundary, and at places in this ore-shoot the stopes are four sets wide or about 20 ft. A fine quality of ore is being mined at this point and a series of shafts will be sunk through the hanging wall into this vein from which a continuous glory hole will be opened for a distance of 700 ft., the waste from the wall above being used in back-filling the lower workings as the ore is extracted. A similar process will be employed on the Red Top and Lucky Boy claims in developing the Red Top vein. The ore reserves have assumed such proportions that it is regarded as more than probable that the company will increase its milling capacity by the addition of further batteries of stamps at the new mill and the old Combination mill will probably be dismantled as its opera-

General View of Goldfield in 1908.

from this vein at the 260-ft. level, and drifts are now being driven both north and south in the vein from the Red Top workings at the 330-ft. level. The north drift, from the Red Top at 260 ft., has been connected with the stopes of the former Consolidated Red Top lease and almost continuous ore of excellent grade is exposed for over 1600 ft. in this vein. The 860-ft. cross-cut on the Clermont has entered the Mohawk-Jumbo ore-shoot which has been followed above at the 730-ft. level, and the ore at the deeper level is superior in quality to that exposed above, carrying seams of exceedingly rich telluride ore. At the 1000-ft. level of the Clermont shaft the cross-cut is being driven rapidly to the west for the Mohawk vein, and other veins will be cut in the intervening territory. Within the next month development at this depth should demonstrate the character and value of the known ore-shoots at 1000 ft. in depth, and in view of the excellent character of the ore exposed at the 730 and 860-ft. levels, great confidence is felt in the result of development at the deepest point in the mines. Delegates to the meeting of the American Mining Congress will be afforded every opportunity to inspect the mines and mills of the Consolidated company and a feature of the mineral exhibit, in addition to an exhaustive display of ores and mill products, will be a full week's clean-up from

tion entails needless expense and a portion of the plant stands above orebodies which are said to be of far more value than the mill.

In opening the Combination vein it is planned to install a large crusher at a point between the apex of the vein and the railroad from which the crushed material will be conveyed to the company's steel cars by means of a belt-conveyor. It has been stated by A. H. Howe, of the Consolidated, that at the November meeting of the directors the subject of enlarging the 100-stamp mill will be considered. This will involve merely the installation of additional stamps, as the crushing, re-grinding and belt-conveying plant is already of sufficient capacity to handle ore for 200-stamps, as are also the cyanide plant and refinery. At the same meeting the directors will consider the payment of an extra dividend in December. The net profits from the company's operations have been more than sufficient to pay the regular quarterly dividend of 30c. per share, and defray all expenses, and have been materially augmented of late by shipments of high-grade ore from the Hampton stope. Experiments are now being carried on by the Florence management with a view to installing a refinery which will treat the concentrate by a process similar in some respects to that employed by the Consolidated company. Several

shipments of high-grade ore have been made from the stopes in the Engineers' vein, and recent development has exposed some new orebodies of great value, one in particular having been opened in territory lying between the former Engineers' and Gem Florence leases and which was missed by a few feet only by the lessees on both sides. The main shaft of the Florence will be enlarged to three compartments to the 500-ft. level, at which point a powerful pump will be installed to drain all the workings, and connection will be made from this shaft with all of the former lease drifts and stopes. At several points in the mine, where development had been abandoned in supposedly barren ground, the resumption of driving or cross-cutting has resulted in the exposure of excellent orebodies, and the Florence mine now has a gigantic tonnage of fine ore blocked out. The most difficult problem of solution which has confronted the Florence management from the inception of the mill has been that of finding adequate space for the tailing. The mill is situated above a rather narrow draw or gully, through which passes the Tonopah & Tidewater railroad, and the expense of constructing retaining walls of waste to keep the tailing within bounds, has been heavy. This difficulty has now been overcome by laying an 8-in. pipe-line from the mill around the Florence hill to a

are coming from the Blue Bull, and shipments are being made by lessees operating on the May Queen, one of the Wingfield groups. Work on a broad scale will be carried on to develop the vein opened on Columbia mountain by B. E. Thomas. This discovery has aroused great interest from the fact that the ore occurs in a contact of porphyry and granite, a formation unique in the district. On this block some exceedingly rich ore, oxidized and showing quantities of free-gold, has been found in the bold croppings rising four feet above the ground.

Development is in progress on the Pipe Dream claim, of the Silver Pick, where a strong vein of quartz, but carrying very low-grade ore, is being followed at 200 and 325 ft. in depth. Cross-cutting is in progress on the Cracker Jack at a depth of 220 ft., on the Mitchell & Fairfield lease, and another 20 ft. should expose the vein passed through above the 100-ft. level, in which an average of \$8 per ton was found. Good ore was opened in the Red Top M. & L. lease, on the Bulldog Fraction, a few hours before the machine house and hoist were destroyed by fire two weeks ago, and the work of installing the new and larger plant is being rushed to completion. On the Atlanta several lease shafts have reached the dacite and there are good indications of ore, the Cherokee lease having cut a good vein at 540 ft. for

Goldfield Consolidated Mill.

point on the Milltown flat adjoining the old Rogers-Syndicate lease, and the tailing will be pumped through this pipe to the flat which is lower than the mill, although not as low as the present tailing pond.

Shipments of ore averaging about \$70 per ton are made daily from the Goldfield Daisy mine, the company work now being devoted to developing the orebodies exposed in the workings of the No. 1 shaft. Mr. Wilkinson, who was recently made president of the Daisy company, is again in charge of operations, and since his return from New York, has granted several leases, two upon different levels of the No. 2 shaft, which is 500 ft. deep, and one embracing the Graham shaft and workings. Good ore is being taken from the 200 level of the No. 2 shaft, the Golden Daisy lease is shipping regularly from the rich vein exposed at the 360-ft. level, shipments will begin within a few days from the Millard-Jones lease and operations are to be resumed on the Toplitz lease in which good ore has been found.

A number of shipments have been made by lessees operating the upper levels of the Goldfield Belmont, and the company work at the 200-ft. level has exposed ore in a blind lead which appears to be the apex of a good orebody. The shaft has been unwatered in preparation for extensive work at the lower levels. The Nancy Donaldson shaft has been timbered to the 100-ft. level, and sinking is again in progress in a good formation. Specimens of high-grade ore

which a cross-cut is being driven at the 600-ft. level. A rich vein has been exposed at the 400-ft. level of the Diadem lease on the Great Bend.

ROSSLAND, BRITISH COLUMBIA.

Le Roi.—Smelter at Northport to Resume.—Development in Centre Star.—Kamloops.—B. C. Copper Co. Active.—Slocan Star.—Influx of American Capital.

It is said that the ore now being taken from the new find in the Le Roi mine will be shipped as soon as the storing space at the mine is filled. This move will, no doubt, necessitate the operation of part of the company's smelter-equipment at Northport, Washington. It is natural that the company should treat this product of the mine and apply the profit therefrom to the development fund. The shaft on the Josie claim of the Le Roi 2, Ltd., is now down 1070 ft., having been sunk 170 ft. since the deepening process began in June last. The shipments from the Le Roi 2, Ltd., were light for the past week, 270 tons, but this was partly occasioned by the attention being given to development. A good body of average ore has been found below the 1600-ft. level of the Centre Star, and at the present time a winze is being sunk on the find to more thoroughly open it. The shipments for the past week were up to the standard, 3730 tons. Things hold steady at the prop-

erty of the Consolidated, and there is no effort at forcing either the shipments or other part of the mine-work.

A deal of considerable importance, especially to the Kamloops district, was consummated in Greenwood last week, when the British Columbia Copper Co. took a bond on seven groups of mining claims, comprising in all about 30 mineral claims, situated in the Kamloops division. The Bonanza, Kimberley, Rising Sun, Giantess, Laura Maxim, and Esperanza groups were included in the deal, which calls for work being commenced in the near future. If the development that will be done on the group by the Copper company proves of value it will no doubt be found advisable to treat the ore at Kamloops and steps will then be taken toward the establishment of the long-sought Kamloops smelter. The effect of the B. C. Copper Co. interesting itself in Kamloops camp will be to stimulate the several companies that have already done a lot of work but are at present inactive owing to lack of interest, and in some cases to lack of funds. Kamloops, of course, may be termed a low-grade camp, but it has been demonstrated

have been taken up by New York men, the Queen by Duluth people, and the Lucky Jim by Spokane capitalists.

AUSTIN, TEXAS.

Iron Ores and Blast Furnaces.—Terlingua Quicksilver Mines.—Shafter Silver Mine.—Mineral Surveys.

Charles M. Schwab, who recently visited the iron ore fields of East Texas, where he leased 30,000 acres of undeveloped ore-lands in Cass county, is reported to have obtained options to purchase more than 100,000 acres containing extensive bodies of iron ore in Marion and Rusk counties. It is announced that mining operations are to be started as soon as the necessary machinery can be installed. Mr. Schwab is said to have under consideration the erection of a large iron and steel plant at Port Arthur, Texas. His iron ore fields are situated about 200 miles north of that place. An iron furnace was operated at Jefferson, in Marion county, for many years. The ore is high-grade. The State of Texas has a 75-ton furnace at Rusk, which is operated in connection with the penitentiary at that place. Considerable exploitation work has been going on for several months in the Llano iron ore fields, about 100 miles north of Austin. R. H. Downman, of New Orleans, owner of the Olive mine, has had drills at work testing the extent of the orebody. The results are reported to have been satisfactory.

The activity in the Terlingua quicksilver district, in Brewster county, still continues. A number of new operators have entered that district and are developing promising claims. The erection of two new furnaces is planned. W. P. Gaines, of Austin, and associates own a large number of sections of land, scattered through the district, and are having the different tracts systematically prospected by William B. Phillips, formerly director of the State mineral survey. Mr. Phillips opened up the famous Chisos mine, owned by the Chisos Mining Co., situated in the Terlingua district. This mine has been producing cinnabar ore at the rate of more than \$15,000 in net value per month for several years. Mr. Phillips has already located several good veins upon the sections of land owned by the Gaines syndicate, and development will soon be started under his direction. The development of the Terlingua district is handicapped by the lack of a railroad. It is 90 miles to Alpine, the nearest railroad shipping point. Enrique Creel, of Chihuahua, Mexico, is at the head of a project to build a railroad from his rich mines in Mexico to a connection with the Southern Pacific at Alpine in order to afford him a shipping outlet for the ore. The route of this proposed road is through the Terlingua district.

Charles Moser, who is operating a rich silver-lead mine in Mexico, just opposite Boquillas, Texas, will soon have ready for operation the aerial tram which he is erecting to convey the ore from the mine across the Rio Grande, a distance of six miles. He will then begin regular shipments to the smelters in the United States. The ore will be hauled in wagons, drawn by traction engines, from the river crossing to the nearest railroad point at Marathon, Texas, 100 miles. The famous silver mine at Shafter, Texas, which is owned by a syndicate of California men, is keeping up its wonderful record of production. This mine has yielded about \$14,000,000 in silver during the last 20 years. It occupies the unique distinction of being the only producing silver mine in Texas. Many apparently good claims have been located in the Shafter section, but little effort to develop them has ever been made. In the vicinity of Alpine, particularly in the Davis mountains, surface outcroppings of gold and silver veins have been found from time to time, but owing to the unfavorable and oppressive features of the State mining law no attempt has been made to exploit these discoveries.

The State mineral survey, which was created several years ago as an adjunct of the State University, had just begun a complete survey of the mineral deposits of Texas when its existence was ended by failure of the legislature to make any appropriation for the new department. An effort will be made to have the legislature at its next regular session make provision for continuing the work.

British Columbia.

that the mines around Kamloops can be profitably worked if the required capital is employed. The B. C. Copper Co. has had the Windfall and Prince Fraction surveyed. This property is situated on the West Fork of Kettle river. It is stated that the bond price on the Sappho property, recently taken over by the B. C. Copper Co., was \$20,000. The ore on this claim assays from 8 to 10% copper.

It is announced that the Slocan Star mine, a rich silver-lead property at Sandon, and which has been much hampered in late years by costly litigation, is about to be reopened on a substantial scale. A new find of rich ore was made upon the property not long ago, so that the management will have something good to start on. It is also good news to hear that the Sullivan group will resume work at an early date. This is one of the largest lead-zinc mines in the Kootenay district. It is likely that the smelter of this concern will also be repaired. Both mine and smelter were recently acquired by a subsidiary company of the Federal Mining & Smelting Co., so that a good financial backing is assured. The Enterprise is a new mine on the shipping-list for the past week, having sent an 8-ton shipment of select ore to the Trail smelter. There appears to be quite an influx of American capital to the growing mines of this district during the last few months. This is observed in the opening of the McGillivray creek coal mines by Minneapolis and Spokane men; the acquirement of the Highland-Buckeye-United group, near Ainsworth, by New York capitalists—who, by the way, have just bought an air-compressor and drilling-plant, also the Fife mines

BUTTE, MONTANA.**Butte-Ballaklava. — Heinze. — North Moccasin. — British-Butte.**

The Butte-Ballaklava Copper Co., the youngest of the mining companies to be organized for operation in the Butte district, is one of the first among them to reach a producing stage. The property is opened to a depth of nearly 1500 ft., with 11 levels from the 100 to the 1400-ft. Five veins have been developed in the ground and two of them are large and opened sufficiently for a good production. Steel ore-bins of 500 tons capacity are about completed, and during the coming week the company will begin mining and shipping ore from three or four levels. For a time shipments will be limited to probably 100 tons per day. Mining will be somewhat interfered with by work in the shaft, as the company will shortly start enlarging the shaft by raising from the 500-ft. level to the surface. Down to 500 ft. the shaft has but two compartments, but from that to below the 1400-ft. level it has three compartments. The work will begin about October 1. The Butte-Ballaklava is owned chiefly by Duluth capitalists, but the stock, of which there are but 250,000 shares, is being well distributed and has just been admitted for listing on the Boston exchange. The property of the company consists of the Burke and Ballaklava claims, which

a remarkable average for such a large vein. It contains many small seams of glance and bornite. No driving has been done on the vein. At the 1400-ft. level all the veins are found, on their dip, south of the shaft. The only vein being opened there now is No. 3, which is showing up even better than on the levels above. The Butte-Ballaklava is operated entirely by electric power, and is probably the only Butte company that has discarded steam altogether, and in doing so it has made a saving of 60% in the cost of its power. Before the introduction of electricity the company worked only to a depth of 500 ft., and operated but one drill, but its monthly cost for power was about \$1500. Now the cost is below \$600 per month and the company is working to a depth of 1400 ft. and is operating six drills, so that the actual saving is probably nearer 75% than 60, considering the increased depth and number of machine-drills. P. H. Nelson, of Duluth, an experienced mining engineer, is vice-president and general manager of the company. When the shaft is completed the company ought to be able to mine and ship 500 tons of ore per day without difficulty. It is in good financial condition, having a working fund in the treasury of about \$300,000, and operations are conducted more economically than at any other property in the district.

**Butte Mines.**

were long tied up in an unsettled estate, and adjoin on the east the Speculator and Edith May properties of the North Butte company, carrying the veins of those mines. On the 100-ft. level the actual depth from the surface is only about 70 ft., and the ore comes to the grass roots. Three veins have been opened on that level and one of them yields 6.5% copper and 50 oz. silver per ton. The same veins are now being opened on the 300-ft. level. Some ore has been shipped from the 500-ft. level for the purpose of getting smelter returns on it, and one car netted the company \$990, the copper content averaging 14.5%. At 700 ft. the veins have also been well developed and the ore runs from 4½ to 7% copper, with 7 oz. silver per ton. The largest vein on this level is 7 ft. wide and has been driven on 125 ft. On the 800-ft. level, No. 3 vein shows a lot of glance and bornite, 4 ft. of the vein giving an average of 7% copper and 8 oz. silver. The orebody has been followed upward for 30 ft. and continues equally valuable to that height. On the 1200-ft. level, No. 3 vein shows a decided increase in size, the entire width not having been determined. The face of the drift is all in ore, the average assay showing 4.77% copper, 6.4 oz. silver, and 60c. gold per ton. A seam of pure bornite 18 in. wide in the side of a drift assays 35% copper and has been developed a distance of 120 ft. It extends both above and below the drift. On level No. 13, No. 1 vein fills the entire shaft and station, a width of 40 ft., and the whole vein gives an average assay of 3.5% copper, 6 oz. silver, and 50c. gold;

The report emanating from Butte a few weeks ago that Heinze was completely out of the Ohio Copper Co. is being confirmed from various sources. The indications are that the Cole-Ryan interests have succeeded Heinze. From the same authority which gave out the story about Heinze's elimination from Ohio Copper now comes a rather startling suggestion that if Heinze should also consent to his elimination from Davis-Daly he could get reasonable assurance that he would never be prosecuted on the indictments now standing against him in New York.

The North Moccasin Gold Mining Co. appears to have been another Barnes-King in the way of promises and failure of performance. The property of both companies is in the Kendall district. The Bank of Fergus county has just instituted proceedings against the North Moccasin company to foreclose on the \$100,000 mortgage bonds and for \$10,000 due on an over-draft. The court is asked to appoint a receiver. The North Moccasin company sold considerable stock, but its shareholders are not so numerous nor so hard hit as the shareholders of the Barnes-King.

A dispute with the engineers' union has resulted in a complete suspension of operations of the big gold-dredge of the British-Butte Mining Co. near Butte. The engineers asked for heat during the recent cold spell, and Mr. DeHara, the manager, decided that it wasn't cold enough. The walking delegate interceded in behalf of the engineers and Mr. DeHara became angry and shut down the plant.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Slag Calculation.

The Editor:

Sir—The enclosed calculation is made from a clipping from a published analysis which is as follows: SiO_2 , 52%; CaO , 9.3; MgO , 0.3; S , 3.5; FeO , 12.1; Al_2O_3 , 4.55; Ag , 3.82 oz.; Au , 0.06 oz.; Cu , 4.35%. As the ore is high in SiO_2 , the best smelting mixture would be a bi-silicate,* that is the oxygen ratio of base to acid as 1 to 2, which would give SiO_2 , 48%; FeO , 32; CaO , 20.

| | Wt. | SiO_2 | MgO | S | FeO | Al_2O_3 | Cu | Ag | Au |
|----------------------------|--------|----------------|----------------------------|------------|--------------|-------------------------|-------------|-------------|-------------|
| | in lb. | % lb. | % lb. | % lb. | % lb. | % lb. | % lb. | oz. | oz. |
| Ore | 2000 | 52 1040 | 9.6 192 | 3.5 70 | 12.1 242 | 4.55 91 | 4.35 87 | 3.82 | 0.06 |
| CaO 53% 280 | | | 53 149 | | | | | | |
| | | | Al_2O_3 91 | | | | | | |
| FeO 64% 703 | | | | | 450 | | | | |
| FeO 64% 131 | | | for matte | | 84 | | | | |

No. of pounds Cu per ton of mixture 55.88.

Ounces Ag per ton 2 4534.

Ounces Au per ton 0.03852.

Total value per ton \$8.59 U. S. currency.

Cu in matte 36.099%.

The SiO_2 of the bi-silicate mixture as given above is as 1 is to 0.666 FeO . The SiO_2 is to CaO as 1 is to 0.416. To make the mixture a bi-silicate as above, the SiO_2 , which is 1040 lb. to the ton of 2000 lb., would require 432 lb. CaO , or 0.416 lb. to each pound of SiO_2 . After making a calculation to use the 192 lb. of CaO and MgO , also considering the 91 lb. Al_2O_3 as a base, it would still leave the mixture short 149 lb. CaO , but if limestone containing 53% CaO was available, it would require 280 lb. of such limestone to furnish the required CaO . As the SiO_2 is to FeO as 1 is to 0.666, it would require 692% FeO to flux the 1040 lb. SiO_2 , or 0.666 lb. to flux 1 lb. SiO_2 , as the ore contains 12.1% or 242 lb. FeO , and lacks 450 lb. of the required flux. If, for an example, a hematite ore could be procured that would run 64%, as I have figured in the calculation, 703 lb. hematite would be necessary to furnish the required 450 lb. FeO . As 84 lb. iron would be necessary for the matte, it would take an additional 131 lb. of hematite. As Cu requires 0.25 lb. S to form Cu_2S , it will require 21.7 lb. S for the Cu , and the 48.25 lb. of S will take up Fe to form FeS at the rate of 1.75 lb. Fe to 1 lb. of S . The total, not counting loss, would make 241 lb. of matte, namely, S , 70 lb.; FeO , 84 lb.; Cu , 87 lb. As the SiO_2 equals 1040 lb., the CaO 432 lb., the FeO , not counting what goes into the matte, equals 692 lb., and 241 lb. matte, a total of 2405 lb., the 241 lb. of matte would be about 10%, not counting losses, or 10 tons into 1. If there should be much of an oxidizing action in the furnace, and a volatilization of the S should take place, a higher concentration could be expected, but with the high SiO_2 percentage and with most of the Fe present in hematite, with very little pyrite or S , and a moderate percentage of CaO , the smelting of such a charge would border on pyrite smelting. Although the SiO_2 is rather high, the melting point of such a charge would be about 1130°

C . Although the heat necessary to melt such a highly silicious charge is lower than some of the singulo-silicate and three-to-four silicate formations of from 10 to 16% lower silica content, it would still be necessary for a higher degree of heat for such acid slags to flow freely. The disadvantages of such a slag would be its viscid and sluggish nature, the lower tonnage put through the furnace, and a train of evils brought about by such a high SiO_2 percentage. The advantages of the slag would be that less flux would have to be used, and where the silicious ore carried gold and silver, a higher percentage of SiO_2 could be used in the ore charge, and less barren FeO and CaO smelted. A high heat would have to be maintained and from 12 to 14% of first-class coke used in the charge. The percentage of Cu in the matte (87 lb. Cu to 241 lb. matte), equals 36.009% Cu . As the entire weight of SiO_2 , FeO , and CaO is 2164 lb., the proportion of the slag is practically SiO_2 1040 lb., 48%; FeO 692 lb., 32%; CaO and earths 432 lb., or 20%. The specific gravity of such an extremely acid slag would be low, and allow the matte to settle well. To make the same ore-mixture into a 3 to 4 silicate (oxygen-ratio), SiO_2 38.16%, FeO 37.48, CaO 24, would require several hundred pounds more flux to the ton of ore. The melting point of such a silicate would be about the same as the bi-silicate mentioned in this article, but with lower SiO_2 and higher base content, it would flow more freely. It would be a matter of experiment to ascertain which would be practically the best slag to make commercially.

G. I. DINWIDDIE.

Chihuahua, Mexico, July 31.

Cyanide History.

The Editor:

Sir—In your issue of July 3 my former colleague and late partner, J. S. MacArthur, takes exception to my statement "that the vacuum-pump and cyanide process were both introduced into South Africa before J. S. MacArthur ever arrived in that territory." He asserts that I went to South Africa early in 1889, and that it was only in June 1890, and under his supervision, that the first demonstration of the cyanide process took place in South Africa. The facts I stated are so obvious, and so readily capable of verification, that I cannot understand Mr. MacArthur's interposition at all. Mr. MacArthur traverses my statement, but offers no evidence.

First, as to the vacuum-pump: Mr. MacArthur, on the morning of his arrival at the works, May 2, 1890 (he arrived in Johannesburg in time for lunch on May 1), saw a vacuum-pump installed at the Salisbury cyanide works for the purpose of recovering solution from the charges being treated. The fact is indisputable; records exist; so that there seems no object in his exception to this portion of my statement. As for the introduction of the cyanide process, we may take it, without quibbling or equivocation as to the meaning of the word, the act of introducing or bringing to notice, that this took place in 1888. At any rate, prior to the end of that year negotiations had been entered into with the Maritzburg Boards which later on culminated in their being the very first to lay down, acquire, or use cyanide

plants, and investigations had also been made regarding the treatment of the ores of the Robinson, Crown Reef, and Ferreira companies, which were the first concerns at which the Gold Recovery Syndicate (or Hennen Jennings) erected cyanide plants on the Rand after the Salisbury (Maritzburg company) demonstration-plant or the small private plant laid down for the purpose of treating the Jubilee (Maritzburg company) tailing.

Moreover, it was in 1888 that a step vital to our interests was taken in South Africa, the successful raising of an action for the cancellation of the Siemens cyanide patent, which, post-dating us at Cape Town, was of earlier date than our own in the Transvaal. This Cape Town action enabled us to have the Transvaal Patent Register rectified, but of the vital importance to us of this early step there can be no two opinions, and I am rather surprised that Mr. MacArthur should have overlooked it and thought South African cyanide history commenced in 1889. Of course if Mr. MacArthur wishes to make some fine definition of the word 'introduction', and to mean that no introduction of the process, in spite of all previous work, could take place in a country until a large 12-vat plant had been erected, then he is faced with the *reductio ad absurdum* that the cyanide process can never have been introduced into Australia at all by the Cassel company, in spite of its being the field of their earliest mission; and secondly, that I must have had the honor of introducing the cyanide process to Mr. MacArthur himself, for up to the time of his arrival at Johannesburg he had, so far as I know, never seen a practical cyanide plant at work—at any rate of any size—other than our experimental apparatus at West Scotland street, and possibly an experimental vat or so rigged up for the purpose of some test in America, whereas on the morning of his arrival at the works I had the pleasure of running through a couple of charges of Salisbury tailing, just to show him how the plant worked, for an extraction of 99.5%—which, of course, is not attained without much previous experience—by the aid of the very vacuum-pump to whose existence he apparently takes personal objection.

There is therefore no difficulty in disposing of Mr. MacArthur's objections to my statement as to the existence of the vacuum-pump and of the cyanide process in South Africa prior to his arrival in that territory, and the early history given above, which may be regarded as official, shows that Mr. MacArthur is incorrect—or else his memory has failed him—in stating that I went to South Africa early in 1889. He is also incorrect in stating that it was only in June 1890 that the first demonstration of the cyanide process took place in South Africa, unless again he has some equivocal meaning of the word 'demonstration'. Prior to the date he mentions we had earned a large sum of money, over £200, for the treatment of concentrate, 'blanketings' and 'skimpings'. We had held various demonstrations, including possibly the most important we ever had there, namely, that attended by Messrs. Von Hessert, Eckstein, Jennings, Phillips, Davis, Dormer, Williams, Michell, and Mr. MacArthur himself, at which I shook some precipitate off the filiform zinc and

melted it in the presence of the spectators so that they might see that the gold was actually extracted. But long before this, material from all over the country had been tested, reports thereon sent to the respective Boards, a number of propositions had been made, and an offer received for the acquisition of the very demonstration-plant to which Mr. MacArthur refers. Indeed, I had already contracted to treat 100 tons of 'buddlings' of the company concerned, by this very plant, which was designed by me (vacuum-pump included) in October 1889, at the time Mr. MacArthur left for his duties in Colorado.

ALFRED JAMES.

London, August 11.

The Editor:

Sir—In your issue of July 17 you publish an intemperately worded series of statements by George Mackenzie, who appears to be the new secretary of the Adair-Usher process at Johannesburg. He controverts the statements of Alfred James regarding this process in his annual article dealing with progress in cyanidation.

I enclose copy of a letter from Mr. Adair himself, which appeared in the *South African Mining Journal* of August 7, 1909, with the request that you publish it. This seems only fair to Mr. James, since Mr. Adair states that "in his remarks Mr. James fairly and rightly hits the nail on the head."

BERTRAM HUNT.

San Francisco, September 14.

To the Editor, *South African Mining Journal*:

Referring to the correspondence between Alfred James and the Adair-Usher Co.: As the discoverer of the process under discussion known as the Usher, I should like to make a few remarks for the information of the industry. Mr. James, unwittingly, and the company, discuss only the most ineffective form of the plant, and in his remarks Mr. James fairly and rightly hits the nail on the head. The fixed-pipe arrangement requires two transfers, that is, one from the de-watering vat, and one from the vat in which the gold is partly dissolved by agitation. In the moving form of the plant, one transfer from the de-watering vat is all that is necessary to obtain better results. Both parties are literally and verbally correct. With some knowledge of processes, I wished the company to install the most effective, that is, maximum-profit plant, but on this point I was over-ruled by the united wisdom of the technical, semi-technical, non-technical, and neutral components of the company. Some slight and trivial difficulties with the moving plant frightened these luminaries into taking the easier and less courageous road to fortune, with the success that might have been anticipated. The present plant is not a failure. As the originator and improver thereof, I could hardly say less than that, but it is a defect from which the other form is free, namely, that channeling is inevitable, a fact acknowledged by the company, and, therefore, being less effective and profitable, it must eventually be replaced by the moving part with one transfer only, which will, I trust, meet with due appreciation by Mr. James and the industry.

ALFRED ADAIR.

Troyeville, Transvaal, August 4.

The Commercial Orient.

The Editor:

Sir—You print a very interesting article in your issue of August 28 on 'Mineral Deposits in Trebizond'. In that connection I wish to recommend consideration of the following table showing percentage of imports which appeared recently in the New York Sun:

| | Total imports. | Per cent from U. S. |
|----------------------------------|----------------|---------------------|
| India | \$443,000,000 | 2.4 |
| China | 342,000,000 | 8.6 |
| Japan | 317,000,000 | 17.3 |
| Straits Settlements | 199,000,000 | 1.0 |
| Hong Kong | 180,000,000 | 4.9 |
| Turkey (Asiatic and European) .. | 133,000,000 | 0.7 |
| Egypt | 129,000,000 | 2.2 |
| Dutch East Indies..... | 88,000,000 | 1.6 |
| Philippines | 81,000,000 | 16.4 |

What sort of a chance has an American mining man or machinery manufacturer of exploiting the Trebizond minerals? Until someone opens a down-right fight, every corrupt influence in the American Government will give preference to foreign shippers and ship-owners.

EDWARD P. NORTH.

New York, September 4.

Gases from Explosives and Mine Economy.

The Editor:

Sir—I was much interested in the editorial and the article by Wm. Cullen on 'Gases from High Explosives', in your issue of August 28. I recently examined an interesting gold mine in Alabama where some experiments have been made with different explosives. The mine is the Hillabee, managed by T. H. Aldrich, Jr. Mr. Aldrich claims to get much better results by using three of the strongest detonators in the last stick in each hole, instead of the one formerly used. He uses nitro-gelatine. Most shots are fired by electricity, but some are fired by fuse. Clay is used for tamping. In drifts, 5-ft. holes are drilled, and in stopes 15-ft. holes, in hard quartz. A hole charged with gelatine and three detonations takes one stick less of explosive, and the extra detonators cost less than one stick of gelatine. It would be interesting if Mr. Cullen or others would experiment with stronger detonators or more of them, and publish the results.

ALBION S. HOWE.

San Francisco, August 30.

Radium Ore.

The Editor:

Sir—I notice on page 332 of your issue of September 4 that a movement has been started under the generous patronage of Thomas F. Walsh, of Colorado, to encourage prospectors and others engaged in mining in their search for ores containing radium. In the appeal accompanying his contribution Mr. Walsh only mentions 'pitch-blende' or uraninite as a source of radium, and quite correctly remarks that Austria has a practical monopoly on this ore by virtue of its large Bohemian deposits. There is, however, another ore of radium which, to my knowledge, has so far only been found in Colorado, and which

promises to become an important one for the production of that metal. Its name is carnotite, that is, a uranyl vanadate, of canary yellow color, and ocherous appearance, mostly occurring in sandstone.

While, at this early stage of our investigations into the properties of radium and its manufacture, but little can be said in regard to the respective richness in radium of these two minerals, pitch-blende and carnotite, my personal observation lead me to believe that the Colorado pitch-blende, which has so far been marketed, is of lower degree of radio-activity than that mined in Bohemia. Mme. Curie has found that the Bohemian mineral has a radio-activity of 8.3, 7.0, and 6.5, respectively, and in the three mines which were worked at the time these investigations were made, while, for instance, the Cornwall pitch-blende which was submitted showed a radio-activity of only 1.6. The Colorado carnotite, however, had a radio-activity of 6.2, and, considering that these samples came from the earliest workings, it is safe to predict that the radio-activity of the Colorado carnotite will at least reach that of the Bohemian pitch-blende, if it does not surpass it. Apart from this there are other considerations which make carnotite a highly desirable ore for the extraction of radium. Carnotite contains variable percentages of vanadium, and this metal and its ores are also highly priced and much sought after, and it is likely, therefore, that carnotite will yield commercial quantities of both uranium oxide, which is the base for making radium or highly radio-active chemicals, and vanadium oxide, from which ferro-vanadium for steel-hardening purposes is made.

A few small experimental plants for the treatment of carnotite have been built in Colorado, and the result appeared to be encouraging. The valuable oxides thus obtained have been shipped to Europe through the inexperience of those who had to dispose of them, and who apparently did not know that there is a ready market for them in New York. It seems advisable, therefore, to encourage not only the search for pitch-blende, but also that for carnotite, which is distinctly an American mineral. Colorado is undoubtedly the most promising State, as already, in the year 1905, H. C. Demming, a geologist from Pennsylvania, after having made an investigation of the radium-bearing rocks of Colorado, said that there are the following 12 counties that can boast of having ores of radium in commercial quantity: Boulder, Clear Creek, Delta, Dolores, Gilpin, La Plata, Mesa, Montrose, Rio Blanco, Routt, San Miguel, and Summit.

E. SCHAAF-REGELMAN.

New York, September 13.

Production of graphite, according to the United States Geological Survey, in 1908 fell off more than nine-tenths as compared with 1907. This great decrease was chiefly due to the total suspension of operations by certain Georgia firms which had been mining a graphite schist for use in fertilizers. This class of graphite, however, was of comparatively little value, and the reduction in total value due to its cessation amounted to only about one-third, from \$296,970 to \$208,090.

GOLD DREDGING IN SIBERIA.

Written for the MINING AND SCIENTIFIC PRESS
By J. B. LANDFIELD.

The extensive and rich placers of Siberia have not, thus far, proved very profitable as dredging fields. In several regions, during the past ten years, dredges have been set up and placed in operation, notably in the Ural, in the Yeniseisk *taiga* region, and on the Zea and its tributaries, but with few exceptions they have proved unsuccessful. The reasons for these failures deserve looking into, because of their bearing on the future development of the country. The gold mines of Siberia at the present time consist almost entirely of river placers. The Ural region has a number of quartz mines, and about two-fifths of its gold production comes from this source, but administratively this belongs not to Siberia, but to European Russia. Of Siberia proper, nearly 95% of the gold-production is alluvial. The gold-bearing grav-

pierced with 1-in. holes, and forming rude grizzlies. These plates are sometimes replaced by loose planks that have 1½-in. holes bored in them at intervals of 6 in., these holes being connected by grooves on the under side. This long tom, which is called a 'butara', is set at a grade somewhat steeper than that of an ordinary sluice-box, and a very modest amount of water is let in at the upper end. The gravel is usually brought up in wheelbarrows and dumped in on one side at the head. On either side of the 'butara' are men with instruments that look like dull hoes, with which they break up the lumps and assist in the washing of the gravel. For this work five or six men are required. At the lower end of the 'butara' is a kind of grizzly with 5⁄8-in. holes, and the tailing that is stopped here is hauled away in wheelbarrows. The finer material then drops to a short, steep sluice in which are placed cross-riffles at intervals of 8 to 10 in. The riffles are frequently crescent-shaped, with the concave side up stream. Altogether the

The Butara or Washing Machine in Siberia.

els of Siberia are widely distributed. Each of the great rivers has among its tributaries several 'basins' from which placer-gold is produced, and some of these rival in richness any to be found elsewhere in the world. The richest of all are probably the placers of the Vitim and Olekma river basins of the Lena region, where \$25 to \$30 per cubic yard is not uncommon, but in the valley of the Yenisei, along many of the tributaries of the Amur, notably the Zea, and elsewhere throughout Siberia, are to be found placers that would cause big stampedes if they were situated on the other side of Bering Sea.

The methods of working are crude. In most cases a drainage ditch is dug from the lower end of the ground, while at the upper end, if necessary, the water is diverted, and a portion of it is conveyed to the washing machines in wooden sluices. The washing machine almost universally used in Siberia consists of two parts, a long tom and a short, steep sluice. The long tom is usually 5 or 6 ft. wide and 20 long. It is built of 2-in. pine or spruce planks, the bottom planks running cross-wise. Near the bottom, raised about 2 in. above it by cleats, are laid iron plates

machine is very crude and allows a lot of gold to get away. It is expensive to operate in spite of cheap labor, and the fundamental error, an error that is everywhere to be noticed in Siberia, is that of not letting water do the work.

The Siberian mine-owner is a curious type of man. In small transactions he is shrewd to a degree, but he seldom has any idea of business organization, and is at the mercy of dishonest superintendents and managers. He is generally satisfied to let things take their own course as long as some profit is coming in, and if there be a deficit, he will borrow from the bank as long as it will loan to him. He seldom analyzes the cause of the deficit. On the other hand he reads or has read to him, for he is frequently illiterate, some account of the methods used in other countries. The conditions under which they are practicable do not concern him much, what interests him chiefly is that, by dredging in California, gold is recovered at a cost of 5c. or less per cubic yard of gravel, whereas it costs him from 12 to 20 times as much.

Except for the cleverness of certain German manu-

facturers, however, few mine-owners would have done more than talk of the ingenuity of the Americans, and dream over the profits possible with such appliances. The German scheme was a clever and simple one, and in the absence of Americans their representatives had the field to themselves. First they ascertained that the placer for which they proposed to supply a dredge contained enough gold to cover the cost. Then they offered to equip the mine with a dredge complete and take their pay out of the gross product, representing to the owner that in this way he ran no risk, as he had nothing to pay in advance. Needless to say many proprietors jumped at the chance. The German company had no experience in building dredges for gold mining, and proceeded to erect poorly made dredges which it sold for \$30,000 to \$40,000. The gold-saving apparatus was crude, and the machinery was not durable, but the Germans could easily get their money out of the gross product before it went to pieces. Noting the growing enthusiasm for dredging, and the profits of the German manufacturers, one of the iron works of St. Petersburg also engaged in the manufacture of dredges. This firm knew just as little of the practical side of the work, but built much more durable machines.

It is not surprising, therefore, that most of the Russian dredging operations set on foot in Siberia proved failures, if for no other reason than their faulty equipment. But there were numerous other causes of non-success. Few forms of gold-mining require so many conditions as a requisite of success as dredging. First of all comes the question of bed-rock and boulders. My observation in this regard is that a majority of Siberian placers, if not too near the head of a stream, are free from large boulders and have a satisfactory bedrock. It is surprising how many of them have from one to three feet of partly decomposed rock as a bed. On the other hand, many of them are overlaid by a stratum of greasy clay which in sluices rolls up into balls and interferes seriously with gold-saving. Besides this there is also the difficulty of frozen ground. The area of permanent frost is, however, much less than generally supposed, and the trouble occasioned by the climate is of a commercial rather than a technical character. In the case of an expensive dredge and outfit, it is a serious matter to let it lie idle six or seven months in the year, on account of interest charges and deterioration.

Labor and fuel are for the most part cheap. Forests abound and wood can be had at the dredge for about \$1.50 per cord. Labor costs from 50c. to \$1.25 per day, according to the locality, and is not good. Individually the Russian miner is an excellent workman, learning quickly, living frugally, and capable of great exertion. In large numbers, however, and especially at distant points, he easily becomes insubordinate and unruly. This tendency has become stronger since the labor troubles and political agitation of 1895. Formerly one of the great labor difficulties was the large number of religious holidays, each of which meant at least two days of idleness, one for the celebration and one for getting sober. Now all the Siberian mines give their laborers two

days in each month, in lieu of Sundays and holidays. Dredges, therefore, wherever technically practical, would simplify the labor problem. The few men required could easily be trained, and they would be found efficient.

The question of management is more difficult. While it is comparatively easy to train efficient workmen in Siberia, it is next to impossible to find efficient and trustworthy superintendents and overseers; in fact, officials of any kind. The technical schools in Russia turn out a lot of men who are too proud to soil their hands with labor, and whose book-knowledge only serves to make them impractical. They are not only impractical, but are without any sense of personal responsibility. To be successful a dredging enterprise in Siberia requires a foreigner, preferably an American, of practical experience, and one who speaks Russian or will acquire it quickly. A superintendent who does not speak Russian is at a great disadvantage; he must depend on the unsatisfactory services of an interpreter, and cannot get into touch with his workmen so as to understand their ways and how to train them.

Few indeed of the Siberian mine-owners who have tried dredging have succeeded in clearing the hurdles of bedrock, boulders, labor, management, winter-charges, and dredge-efficiency, but this is not to be wondered at when one considers the large number of failures in dredging in our own country and the thousands of tons of machinery rusting in placer fields everywhere from Alaska to Mexico. Another problem also faces them; one that is too often neglected in undertaking such operations. It is difficult for the Siberian to realize that the contents of a placer are limited, and that the cost of a dredge must be amortized in a comparatively short period. The average dredging ground which I have examined in Siberia has been shallow, and a good-sized dredge would be kept moving rapidly. It is exceptional to find a deep placer outside of the Lena region, and it is not possible to count on the long period of operation which is the basis of most of the Californian dredging. Two other peculiarities are noteworthy. The gravels in a large number of Siberian placers are 'spotty'; rich streaks and pockets occur without any apparent reason for the concentration, and coarse gold is frequently found in the lower reaches of a stream. I am inclined to regard this as closely related to the climate, which makes it possible for frozen lumps of rich gravel to be conveyed considerable distances and become disintegrated on the spot where they find lodgement. This irregularity makes it difficult to estimate the tenor of ground for dredging. Furthermore in most instances it will be found that the overburden is almost entirely barren and cannot be counted upon to bring up the average.

Notwithstanding the difficulties I have mentioned, and the failures of many of the Russian dredging enterprises, I believe that there is a great future in Siberia for Americans, there is opportunity for applying to the innumerable placers the apparatus best fitted to their individual conditions, and at the same time giving them business-like management. In many cases it will be found that shoveling into sluices is the best solution; in others steam-shovels,

scrapers, and mechanical conveyers and elevators may be advantageous; but there will also be found a large field for dredges designed specially to meet Siberian conditions, where the gravels are rich enough to offset the period of winter-idleness and the increased cost of management.

Heretofore Siberia has attracted but little attention in American mining circles. The general opinion regarding it has been largely based on sensational novels, and on the tales of escaped convicts. It will doubtless surprise many to be told that the summer climate of Siberia, from May to November, is delightful, and that the winter in most parts compares favorably with Montana. The mining laws of Russia are superior to our own in many ways, and personally I have received nothing but courtesy and assistance from all the mining officials with whom I have had to deal. It is true that there exists a party in Russia that believes in 'Russia for the Russian', and is opposed to the introduction of foreign capital, but this does not interfere with the rights of foreigners under the law. Many an unsuccessful manager for an English or French concern has returned to excuse his failure on the ground of official interference, when the real cause has been a poor property or his own inefficiency. It is apparent from the recent Russian journals that there has been this summer a rush of foreign engineers and business men to Siberia looking for mining and other opportunities, and Americans should step in and get their share.

Coal and oil are attracting attention in Panama, according to Claude E. Guyant, Vice-Consul General, who states that Adolpho Aleman has closed a contract with the local Government for the exploitation of certain deposits which he has discovered. In the district of Los Santos, near the Tonosi river, he has discovered six separate veins of coal. These deposits cover a considerable area of ground, but as yet no surveying has been done, nor any experimenting more than the taking of surface samples. Mr. Aleman also claims to have discovered indications of petroleum deposits on this land. The land belongs to the Government of Panama, but Mr. Aleman has been given absolute rights as regards coal and petroleum.

Adsorption is the property by which dyes and other substances are extracted from solution and incorporated into the thing dyed. It differs from absorption, which is incorporation of a liquid as it stands, irrespective of what it holds in solution. Adsorption is especially characteristic of the peculiar substances known as colloids, which form the bulk of clays, and on which their plasticity is believed to depend. The amount of dye, therefore, which a given amount of clay will adsorb from a standard dye solution indicates pretty accurately the proportion of colloids that the clay contains.

A mining location which exceeds the maximum limit is void only as to the excess, unless fraud is shown. The locator has the right of selection of the ground to be retained, even as against an overlapping locator.

RADIUM EMANATION.

Written for the MINING AND SCIENTIFIC PRESS

By F. H. MASON.

The metal radium, if it serve no other useful purpose, and it hardly seems probable that it is doomed to such an unfortunate fate, has been productive of some brilliant researches. In working with radium, the chemist has been privileged to use only the minutest fragments of the metal, and consequently he has had to devise apparatus and methods entirely foreign to those generally employed in research.

Among the latest contributions to the chemistry of radium are the researches carried out jointly by Sir William Ramsay and Robert Whytlaw Gray with a view to determining the atomic weight of 'radium emanation', and finding a place for that substance in Mendeléeff's periodic table. Ramsay and Gray proposed to find the vapor pressures of the emanation at varying temperatures, and from these to determine a place for it in the periodic table. It is not given to ordinary mortals to think in such minute quantities as fractions of a cubic millimetre, and when we say that the quantity of 'radium emanation' taken for the experiments varied from one-tenth to one-eighth of a cubic millimetre, it will convey little to the mind of the average reader. Some idea of the minuteness of the quantity, however, may be obtained from the fact that fine-bore thermometer-tubing was found to be too coarse a piece of apparatus in which to condense the gaseous emanation to a liquid form, so it had to be drawn out, in order to reduce the bore, and, after calibration, the graduations had to be read by the aid of a microscope.

The emanation was collected from radium bromide, $\text{RdBr}_2 \cdot 2\text{H}_2\text{O}$, dissolved in water. Radium bromide continuously decomposes water. The bromide solution was contained in three bulb-tubes, connected with a pump, by means of which the products of decomposition of the water, together with the emanation, could be drawn off as required. The rate of evolution was constant; 25 c.c. of gas being generated in seven days. This gas, mainly the product of the decomposition of water, was conducted into an explosion-burette and exploded. After explosion the volume of gas generally shrank to 0.2 c.c., and always consisted of hydrogen, together with 'emanation'. The quantity of hydrogen varied slightly in the different experiments; the experimenters are at a loss to account for the variation. When sufficient gas had been collected, the 'emanation', together with the hydrogen, was conducted into an apparatus where it was purified from gases other than hydrogen. The gases were then placed under pressure, cooled by liquid air, and condensed to a liquid. The apparatus was then connected with a vacuum-pump, and completely evacuated of gas. In this was the hydrogen, together with a little helium, which was contained in the emanation, both being non-condensable, were removed. The pump was disconnected, the liquid-air jacket removed, and, after the 'emanation' had volatilized, it was forced into the small capillary tube, made from drawn-out thermometer-tubing. The tube was then cut from the apparatus, connected with a compression apparatus, and the

gases compressed until liquid appeared. It was then jacketed at various temperatures, and the corresponding pressures were read.

As it was impossible to accurately weigh the mercury, which only formed a thin thread when forced into the drawn-out thermometer-tube, the tube was calibrated by comparing the length of a thread of mercury at a number of points by means of a traveling microscope. The thread was then sucked into the wider capillary of that part of the tube which had not been drawn out, and which was of even bore, and its length again microscopically determined. The volume of a known length of the thermometer-tube was determined by weighing the mercury that filled it. The quantity of the liquid ‘emanation’ that had to be measured, which, of course, varied in the different experiments, averaged only about 0.00025 cu. mm., and it occupied 0.24 mm. (less than one-hundredth of an inch), length of the tube.

The experimenters describe the properties of the liquid and solid ‘emanation’ as follows: “The liquid emanation is colorless, and transparent, like water, when seen by transmitted light; it itself is, however, phosphorescent, and shines with a color varying with the nature of the glass forming the tube in which it is confined; it might be more correct to say that it causes the glass to be phosphorescent. The color varies from blue to lilac; in silica, it is blue; in lead-potash glass, bluish-green; in soda-glass, lilac; when com-

Further reduction of the temperature changes the color to yellow, and in liquid air it is brilliant orange-red; the color-change takes place in inverse order on warming. The red phosphorescence disappears pretty sharply at 118°.” The boiling point of the liquid ‘emanation’ was found to be -62 or 211° absolute, and the critical temperature 104.5 or 377.5° absolute. The vapor-pressures of the ‘emanation’ are given in the following table:

| Pressure, mm. | Temperature, deg. abs. | Pressure, mm. | Temperature, deg. abs. |
|------------------|---------------------------|------------------|---------------------------|
| 500 | 202.6 | 20,000 | 321.7 |
| 800 | 212.4 | 25,000 | 334.5 |
| 1,000 | 217.2 | 30,000 | 346.0 |
| 2,000 | 234.5 | 35,000 | 356.0 |
| 4,000 | 255.3 | 40,000 | 364.4 |
| 5,000 | 262.8 | 45,000 | 372.9 |
| 10,000 | 290.3 | 47,450 | 377.5 |
| 15,000 | 307.6 | | (critical) |

In the periodic table the group of inactive gases is:

| Element. | Atomic weight (in whole numbers). | Differ- ence. |
|---------------|--------------------------------------|------------------|
| Helium | 4 | .. |
| Neon | 20 | 16 |
| Argon..... | 40 | 20 |
| Krypton | 83 | 43 |
| Xenon | 131 | 48 |

According to Mendeleeff’s hypothesis, which owing to its accurate fulfilment in so many instances,

pressed strongly in soda-glass, the color reminds one of the cyanogen flame, at once blue and pink. On cooling further, the liquid solidifies, and ceases to transmit light, on warming, it again becomes transparent. This gives a means of determining its melting point, using a pentane thermometer, which registered correctly at the ordinary temperature and at the temperature of a pasty mixture of carbon dioxide and alcohol (78.3°C.*). The actual temperature at which the emanation melts is 71°. On cooling further, with alcohol cooled with liquid air, the color of the phosphorescence changes. The solid glows with great brilliancy, like a small, steel-blue arc-light.

*Travers, ‘Experimental Study of Gases’.

is practically accepted as law, it may be expected that other elementary bodies will be found, having $(175 + 44) = 219$, and $(219 + 44) = 263$; that is, at three periods separated by about 44 each, commencing at the atomic weight of xenon. The authors, by a series of curves, in which the boiling points, and critical temperatures (Fig. 1), and critical pressures (Fig. 2), of the ‘emanation’, and of argon, krypton, and xenon, are plotted against their respective atomic weights, endeavor to show that the atomic weight of the ‘emanation’ is, in all probability, 176, and not 219, as has been suggested by other experimenters. They conclude: “We are aware that the deductions drawn from these results, namely, that the ‘emanation’ has an atomic weight of 176, does not

agree with the theory advanced by Rutherford regarding the progressive degradation of radium. Perhaps a non-radio-active substance is simultaneously produced when the 'emanation' escapes from radium. It is possible to speculate that, instead of the equation:

the change actually occurring should be:

Certainly the ingenuity of the experimenters in devising apparatus for determining the vapor density, boiling and freezing points, critical temperature and pressure of such infinitesimal quantities of the emanation, is extraordinary.

RESEARCHES UPON CRIPPLE CREEK TELLURIDE ORES.

*Among the gold-producing districts of the world Cripple Creek district, of Colorado, stands as one of the foremost. This volcanic area, three miles long by five miles wide, embodies a network of gold-carrying veins, running in all directions, intersecting each other and comprising a series of ore-shoots the magnitude of which is inconceivable. Along with the development and mining of the higher grades of ore material has simultaneously been developed, which, although of sufficient value to term ore in some other parts of the world, on account of its refractory nature is left standing in the mine stope or thrown upon the waste-dump. The refractory nature of these ores is due largely to the occurrence of the gold in combination with tellurium, forming a compound (Au-Ag)Te₂, which is represented by the minerals calaverite, or sylvanite, and also to the association or encasement of these gold tellurides in crystal growths of the characteristic mineral pyrite.

The history of the metallurgical treatment of these ores is conspicuous for the number of metallurgical failures which have taken place, due largely to the difference in the physical properties existing between gold telluride and native gold, and partly to the insolubility of the tellurides in cyanide solution. Stamp-milling followed by amalgamation was first tried; concentration failed, while at the smelting works these ores were not desirable owing to their high silicious character. Only after roasting to free the gold of its volatile associate have the ores been susceptible to lixiviation processes. Consequently, roasting, followed by barrel chlorination and concentration has become the popular treatment. This method works well so far as extraction is concerned, but as the amount of low-grade ore standing in the stopes and upon the dumps becomes larger year after year, it becomes apparent that a cheaper method of treatment must be found. With this end in view the Portland Gold Mining Co. experimented extensively.

Fine grinding in cyanide solution followed by agitation and filter-pressing was first tried, but difficulty in dealing with the stubborn sylvanite was experi-

enced, so that efforts were naturally directed toward finding a solvent for tellurium. It was found that the tellurium yielded to some extent under the action of oxidizing agents, and after trying various acid mixtures it was resolved to find an alkaline solvent. The most successful were the alkaline per-sulphates, alkaline hypo-iodites, and cyanogen iodide. The chemical behavior of the alkaline per-sulphates is little known to metallurgists. They are not only solvents for tellurium, but their action when used in connection with cyanide solution is extremely interesting. They act as slow oxidizers or depolarizers, thereby greatly increasing the dissolving power of cyanide solution, and when used in small proportions, 1 to 10 lb. per ton of solution, they do not destroy the cyanide to any great extent. A good deal of theorizing regarding the chemical action of these substances, especially when used in connection with cyanide solutions, has been indulged in. When in solution alone, they act as strong oxidizing agents, as follows:

But when mixed with cyanide solution, their oxidizing influence is greatly retarded. In view of this fact, together with results obtained in small tests, it is evident that the per-sulphates, if produced at a low cost, could be generally used in cyaniding as oxidizing agents. They are quite stable compounds, and when mixed with working cyanide solution would oxidize reducing agents, thus greatly aiding dissolving efficiency and precipitation.

A recent article, 'Cyaniding of Silver Ore in Mexico', by W. A. Caldecott, brings to mind a possible field for these substances as a means of dealing with the reducing agents, which this article states are a great source of trouble. Ammonium per-sulphate is a good solvent for silver, but to what extent this property can be applied in ore-treatment has not been determined.

The following few small tests have been made on the solution from the tailing mill in the endeavor to find the effect of per-sulphates upon cyanide solution when used as oxidizing agents.

Three assay tons of blanket concentrates which assayed 108 oz. gold per ton were put in each of six bottles; in each bottle was poured 262 c.c. of regular 1-lb. tailing-mill solution; this made a three to one pulp, and 10 lb. of lime per ton of ore was added. To the first three bottles respectively, was added 0.1, 0.25, and 0.5 lb. of ammonium per-sulphate per ton of ore; the last three bottles being left as straight cyanide treatment. All the bottles were well shaken and stood over night.

| No. | Cyanide consumed per ton of ore, | Ammonium per-sulphate added per ton of ore, | Solution assay value, |
|--------|----------------------------------|---|-----------------------|
| | lb. | lb. | oz. |
| 1..... | 0.55 | 0.10 | 4.13 |
| 2..... | 0.55 | 0.25 | 4.35 |
| 3..... | 0.55 | 0.50 | 4.46 |
| 4..... | 0.60 | None. | 3.54 |
| 5..... | 0.55 | None. | 3.82 |
| 6..... | 0.55 | None. | 3.72 |

From these experiments is readily seen the effect of the increased dissolving efficiency obtained when an oxidizing agent is used, the consumption of cyan-

*By Portland Met. Soc., Edited by Thos. B. Crowe. Jour. Chem. Met. Min. Soc., South Africa.

ide being practically the same as the straight cyanide treatment. Taking the average solution assay 4.313 oz. of the three bottles to which per-sulphate had been added, and comparing the average solution-assay 3.693 oz. of the three bottles where no per-sulphate was added, and multiplying each average by three (as three to one pulps were used), there is obtained a difference of 1.86 oz. extracted by the addition of small quantities of per-sulphate. The low extraction obtained in either case is surprising, but it is a good example of the refractory nature of the gold. This material had passed through a roasting furnace, through chlorination barrels, over the Wilfley tables, then ground to 60-mesh in 1-lb. cyanide solution, then caught on blankets, and was merely used in these experiments on account of its value to make a decided case.

As stated before, alkaline per-sulphates are solvents for tellurium, and when mixed with cyanide solution completely dissolve the telluride of gold. Several bottle tests were made on ore, using a solution of alkaline per-sulphate as a preliminary treatment followed by cyanide solution, the object being to first dissolve the tellurium, leaving the gold in a condition susceptible to cyanide solutions, but with poor results on account of reasons explained later, except where extreme amounts of per-sulphates were used. There was also tried a treatment using the alkaline per-sulphate and the cyanide together in the same solution, dissolution of the tellurium by the per-sulphate and the dissolution of the gold by the cyanide going on simultaneously, but with uneconomical results due to reasons explained later.

Alkaline per-sulphates, like some other oxidizing agents, liberate iodine from potassium iodide in an alkaline solution, the liberated iodine combining with the alkali present to form alkaline hypo-iodites, which compounds dissolve tellurium; it was, therefore, concluded that the addition of potassium iodide to a solution of per-sulphate plus cyanide would form this tellurium dissolving compound, while the cyanide present would take care of the gold, the two working simultaneously.

For a long time the experimenters were led astray. They had found that an excess of alkali in a solution of potassium cyanide plus potassium iodide, plus alkaline per-sulphate, greatly increased the solubility of gold leaf; test after test with good excess of alkali was tried, believing that the solution that had the greatest dissolving efficiency upon gold, would have the greatest efficiency upon the telluride of gold, and working on the theory that the liberated iodine formed hypo-iodite, which dissolved the tellurium, the cyanide present dissolving the gold, it could not be seen wherein an excess of alkali would be injurious; but failure to obtain a good tailing invariably followed unless we used an uneconomical percentage of per-sulphate. Finally, it was discovered that cyanogen iodide was an exceedingly good solvent for the telluride of gold, and it seems possible to form cyanogen iodide in a solution of this kind by the action of the per-sulphate upon the potassium iodide, the liberated iodine combining with cyanide forming cyanogen iodide:

Knowing the similarity existing between cyanogen iodide and cyanogen bromide, and having some knowledge of the cyanogen bromide process, the experimenters worked upon the theory, that the existence of cyanogen iodide depended upon the absence of excessive quantities of alkali. In following this out it was found that low tailings resulting, even with very weak solutions. A solution of 1 lb. cyanide, plus 1 lb. potassium iodide, plus 3 lb. alkaline per-sulphate per ton of solution, in a pulp of three of solution to one of ore, with 4 or 5 lb. of lime per ton of ore, gave on 1-oz. ore, ground to 100 mesh, tailings of less than \$1, with a consumption of cyanide of about 1 lb. per ton of ore. But the solutions after leaving the ore and standing in contact with the air, lost their cyanide, a hard thing to believe, as the same solution before being applied to the ore would stand in a beaker indefinitely with very little loss of cyanide. Even when in contact with the ore in a bottle this loss was not excessive, but when separated and left to stand, the cyanide in some cases disappeared rapidly. This loss was more pronounced when treating heavy sulphide ores; and it became apparent that it was due to the formation in the solutions of $\text{Na}_2\text{S}_4\text{O}_6$. Sodium thio-sulphate, $\text{Na}_2\text{S}_2\text{O}_3$, being formed by the action of the per-sulphate upon the pyrite, is probably further oxidized to $\text{Na}_2\text{S}_4\text{O}_6$.

When the solutions are in contact with the ore, the reducing action of the ore aids in overcoming oxidizing influences, but when separated, the oxidation becomes more violent. The action of the air seems to have a marked influence on the cyanide destruction, as at any rate, a decided difference in consumption is noted in using closed and open agitators. However, it was found that on passing the solution through the zinc-boxes, the deterioration of the cyanide is stopped, due undoubtedly to the reducing action there.

Experiments in a small way upon the manufacture of sodium per-sulphate by the electrolysis of salt cake yielded a product which, when used in bottle-tests, answered very well, so that it might be produced on a large scale at a reasonable figure.

Potassium iodide, although an expensive chemical, would remain as such in the solution, the per-sulphate causing it to give up its iodine, this iodine combining with the cyanide to form cyanogen iodide, or with the alkali to form an alkaline iodide, or alkaline iodate, but always finally reverting back to an alkaline iodide, as any iodate formed would be reduced to iodide in the zinc-box. Cyanogen iodide is certainly a wonderful solvent for gold tellurides, and its production by this method presents a possible field for ore-treatment. In the practice of using cyanogen bromide as a solvent, one of the troubles other than its cost, is its rapidity of action, as it remains as cyanogen bromide only for a limited period, and does not act sufficiently long to cause the dissolution of the telluride of gold. One can, therefore, readily see that if it were possible to produce it in a smaller manner to that described, a much weaker solution constantly in contact with the ore, would have a decided advantage.

SOLUTION OF KUTTER'S FORMULA.

By L. I. HEWES and JOSEPH W. ROE.

*A graphic solution of Kutter's formula for the flow of water has been worked out by L. I. Hewes in connection with his course in graphic computations, given in the Sheffield Scientific School, Yale University, which may be of interest to those who deal with canals, flumes, and streams.

41.66

$\frac{1.811}{n}$

$\frac{0.00281}{S}$

$1 + \left(41.66 + \frac{0.00281}{S} \right) \frac{n}{R}$

\sqrt{RS}

\sqrt{RS}

Kutter's formula, $V =$

is probably the most accurate of those proposed de-

one for the mean velocity, V , one for the hydraulic radius, R , and one for the slope; a diagonal line, not graduated; and a set of curves for the various values of n , the factor which involves the nature and condition of the bottom. Usually, R and S have been determined; n , assumed, and it is desired to calculate V . In this case the diagram is read as follows: From the given value of R on the middle scale project horizontally to the curve of the n -value assumed; thence project vertically to the diagonal. A straight edge through the point on the diagonal so found and the point on the S -scale determined by the given conditions, will cut the V -scale at the required mean velocity. The chart furnishes a means of determining any one of the four factors, the other three being

and the n -curves cover all the values given in any of the books of reference.

The accuracy of the chart is about uniform for the different conditions. Where the n -curves are acute to the R -scale the scale itself is very coarse, thus compensating for any error due to the obliquity of the curves. Opposite the upper end of the R -scale, where its graduations are finer, the n -curves have turned and are nearly parallel to it, so that an error in reading the R -scale has little effect on the location of the pivot-point on the diagonal. Each of the curves has been checked by calculations, and the mean error of the total readings was only 0.53%. The V -scale, on which the results are usually sought, with reasonable care in reading, will give results correct to within two or three units in the third significant figure, an accuracy well within that of the original data. The selection of n , for instance, is an element which introduces an uncertainty largely in excess of this. Other graphic solutions of this formula have been worked out, but they nearly all involve a set of diagrams, one for each value of n . There have been none where the entire range of factors has been included as conveniently in one diagram.

SIAMESE RAILWAY AND MINERALS.

The new extension of the railway system of Siam will connect at the northern boundary of the British Protected Federated Malay States, on the east side of the peninsula, with the British line from Singapore on the south, which line has only about 150 miles yet uncompleted, and will cross the peninsula and connect with the line now completed between Penang and Singapore on the west shore. When completed, this will form a direct rail connection between Singapore and Bangkok, while a branch line of some 60 miles, which leaves the main line at Patuloong, will extend to Trang, on the west shore, and this port will be connected with the mail port of Penang, 140 miles south, by a fast line of mail steamships. The opening of these lines will serve to bring the entire peninsula into more easy touch with the markets of the world, and serve immediately to develop the resources. By this connection with the mail port of Penang, on the great eastern highway of the world's commerce, Bangkok will be brought four days nearer to Europe through mail and passenger service; and by this connection with Singapore, Bangkok in a few years will find itself on the direct through line, which is sure to furnish the outlet for the British Protected Federated Malay States on the south to British Burma and all the Indies on the north and west.

Today there is direct rail connection between Bangkok, on the east, and Karachi, on the extreme west of India, with the two following exceptions: (1) between Sawankalok in Siam and Maulmein in Burma, 170 miles; (2) between Prome, west of Rangoon, and Chittagong, both in British territory, 350 miles, already surveyed.

From Karachi to the head of the Persian Gulf, a point which the railroad from Turkey is approaching by way of Bagdad, is about 1500 miles by the gulf and land-locked sea, or by a low and level coast, for the most part, on land. The part of the peninsula

through which this road will run is one of the richest in Siam. Especially is this true of its mineral wealth. Little has been done as yet in the way of developing the country, but now Siam will have the opportunity, and it is understood that it is her purpose to open up the region by encouraging the development of its agricultural resources, and by offering inducements to foreign capital by way of mining concessions on attractive terms, to all those who are brought within the new treaty relations. In all these lines of development, perhaps that which is of most practical interest to Americans is the new impulse which will be given to the tin-mining industry. Statistics reveal that from this peninsula, with its continuation to the south, come over two-thirds of the total tin output of the world. All the deposits of importance are derived from and lie adjacent to the great line of granitic upheaval which forms the boundary range between Siam and Tennasserim, the backbone of the Malay Peninsula, and which may be traced down to the Dutch islands of Billeton, Banka, and Sengkep. This great line of granite is practically the source of all the vast alluvial deposits of tin which are found in Siam and the British, Dutch, and East Indian possessions. The Siamese territory in the north of this peninsula is probably as rich in tin as either the British or Dutch in the south, and the deposits are disseminated more or less thoroughly throughout the whole of the Siamese portion of the peninsula. As yet the west coast has produced more tin than the east, but recent developments point to the probability that the future holds quite as much in store for those who endeavor to develop the territory on the east coast.

Color of soils was discussed before the American Chemical Society recently by F. K. Cameron and W. O. Robinson. They found on making an examination of 20 typical red and yellow soils that iron oxides are the inorganic coloring matter of these soils. Manganese is present in amounts too small to contribute to the color. The variations of iron-colored soils are sometimes ascribed to the presence of different hydrates of iron oxide. From the comparatively small variation in soil temperature in near localities where the two tints are present it was reasoned that this view is incorrect, and that the iron is in much the same state of hydration. The color was shown to be due to a film of oxides of iron and aluminum, organic matter, silica, etc., surrounding the soil grains. By comparing the color of soils with the iron content and mechanical analysis, it was proved that the thickness of the film causes the variations in color, the thin film of the colored oxide causing the soil to appear yellow, while a thicker film gives a red shade to the soil. This view was confirmed by precipitating ferric hydroxide upon sands of different-sized grains and upon quartz flour, using such amounts as to keep the percentage of iron constant and vary the thickness of the film.

The term 'oil-bearing strata' is defined by the legislature of California as "any bed, seam, or stratum of rock or sand or other material which contains, includes, or yields earth oil, rock oil, or petroleum oil, or natural gas or either of them."

PHOTOGRAPHY IN MINING.

Written for the MINING AND SCIENTIFIC PRESS
By T. R. ARCHBOLD.

Referring to J. B. Landfields's paper in the issue of the MINING AND SCIENTIFIC PRESS of June 26, on the assistance photography affords in making reports on mining properties, and particularly in regard to the geological features, there are one or two instances which he did not show where a photograph may be used to reveal at a glance what would require a considerable amount of writing to make clear.

With reference to geology pure and simple; I have for some time adopted the practice of coloring the print with crayons. It is only necessary to print on a matte surface, which requires no preparation to make the crayon 'take'. I usually employ special portrait velox for sharp negatives, and carbon velox for thin ones. These being what are termed gas-light papers do not require a dark-room, and give quite as good effects as bromide papers. No artistic experi-

ence is required to rub over the various rocks or formations with a crayon, and if the result should be streaky and show the strokes of the pencil, it can be smoothed down with a piece of india rubber, to give an equal tint over the required part. It is not necessary that the color should be the actual color of the formation, but it should be distinct from the color of the adjacent rock. When a series of photographs are taken of the same occurrence, it is well to adopt one color for each rock.

Mr. Landfield advocates the use of plates where possible on account of their being easier to manipulate. I find the cut films, the 'Kodoid Plate', to be equally as good as glass plates, both for ease of manipulation and for resulting effects. They have, in common with all films, a great advantage over glass plates, namely, notes and drawings can be made on the front, which print through without the slightest blur. To do this on a glass plate would necessitate writing backward on the film. A series of photographs, such as those shown herewith, often enables the reader of a report to grasp at a glance the general trend and position of the workings, the strike and dip of the lode, and the like, and get a much clearer idea of the general situation than could be given in pages of writing. I fully endorse Mr. Landfield's advice as to the size of a camera. A 5 by 4 camera is not too bulky, and the plates are large enough in themselves

to be of practical utility. They are a convenient size to enlarge without undue expense. When possible it is better to develop the plates before leaving the locality, as the most careful photographer may make a wrong exposure from time to time, and if faulty they can be repeated. The prints are better enlarged, and to those who have not attempted it, I may say that a bromide enlargement is a simpler and easier matter than a direct print on bromide or any other paper. In making a geological section of a range of hills, for example, a simple and quick method is to project the negative on to a sheet of drawing paper, either by a lantern or by fixing the camera in a window, in the usual way adopted for enlarging with the ordinary field camera. By projecting the view on the required size of paper, the outline of the hills, and all the important points, can be outlined with a pencil, and the rocks sketched in afterward. When traveling it is well to have all chemicals, especially developer, in as concentrated a form as possible. There are many good developers on the market, but I find rodinal as satisfactory as any. It works out fairly cheaply, keeps indefinitely even after the bottle

has been opened, does equally well for plates, films, or paper, and does not stain. The proportions I use for either plates or paper are, rodinal 1 dram, 10% potassium bromide 5 drops, and water 2 ounces.

Graphite is of growing industrial importance. The fact that it is nearly pure carbon, is relatively inert chemically, and volatilizes only at high temperatures makes it of exceptional value in the manufacture of crucibles, muffles, stirring rods, etc. Most of it used for these purposes, however, is imported from Ceylon. Another important use is for lubricating. The addition of graphite to oil results in lower friction than would be obtained by the use of oil alone. The quantity of oil required is also reduced, and a lighter grade or oil of inferior quality may be employed. Graphite can also be used as a lubricant alone. The use of graphite mixed with clay for lead-pencils is well known. The more graphite and the less clay, the softer the pencil; the less graphite and the more clay, the harder the pencil. Formerly every American pencil manufacturer had to import his graphite from Bohemia or Bavaria; but about ten years ago a large deposit of amorphous graphite was discovered in Sonora, Mexico, which proved to be of excellent quality for pencil making, and the American pencil trade now relies mainly on this source. Graphite is also used for coating foundry facings.

THE ROOT POSITIVE-BLAST BLOWER.

Written for the MINING AND SCIENTIFIC PRESS
By L. S. AUSTIN.

A silver-lead smelting-furnace 42 by 120 in. at the tuyeres, and consuming a maximum of 18% coke, requires 3250 cu. ft. of air at sea-level, on the assumption that one pound of coke requires 130 cu. ft. of air to burn it to CO₂. As the height above sea-level varies, a corresponding correction should be applied, increasing this volume. Thus, at the elevation of Leadville, there would be needed 4875 cu. ft. of air, the atmosphere having a density of but two-thirds that at the sea-level. To this must be added 25% for slip and leakage. This will add one-third to that just figured, making in all 6500 cu. ft. per minute.

- Let *w* = pounds of charge smelted per minute.
- p* = ratio of coke to charge (for 18% coke = 0.18).
- c* = pounds of air per pound of coke.
- m* = number of cubic feet per pound of air.
- v* = volume of air required per minute.
- x* = slip, and the leakage of the blast-main and at the furnace.

Then 1-*x* = loss by slip and leakage and

$$v = \frac{wpcm}{1-x} \quad \text{and} \quad w = \frac{v(1-x)}{pcm}$$

The weight of air will decrease for a specified volume, as also will the capacity of the furnace, and accordingly we will have of the above calculated weight:

| Elevation, ft. | Per cent. |
|-----------------|-----------|
| Sea-level | 100 |
| 2500 | 91.0 |
| 5000 | 82.5 |
| 7500 | 75.1 |
| 10,000 | 68.2 |

The following are data for positive-blast blowers:
The above are the maximum capacities at sea-level,

retical, not allowing for slip. (d) The diameter of the pipe-opening is such as to make a velocity of 35 to 45 ft. per second, and hence it is well to increase the diameter of the blast-main as follows. For any length of pipe up to 50 ft., make it 20% larger diameter than the blower-outlet; from 100 to 200 ft., 30% larger, and if the distance be over 200 ft., make it 50% larger. (e) The weights are those of the blower complete with pulley, and ready to set on the foundation. (f) The sizes for the corresponding furnace can only be approximate, but still suited to the blowers specified. (g) The horse-power is needed at 2 lb. for 1000 cu. ft. per minute, and is easily computed from the nominal capacity, which makes no allowance for slip. (i) The capacity of the furnace, which depends upon the pounds of coke burned per minute is calculated from formula (2), and the weight, *w*, multiplied by 1440 will give the capacity in 24 hr. The slip and leakages are assumed to equal 25%, and the fuel 20% of the charge. Ten pounds of air are taken per pound of coke, and 12.5 cu. ft. of air to the pound at sea-level. (j) The percentage of coke in regular matte-smelting may be taken at two-thirds of that used in lead-smelting, and therefore the capacity of the matting furnace is made one-half more than that of the corresponding lead furnace. It is noticed in regard to these capacities that they are maxima for the speeds given, and would be reduced for lower speeds and greater elevations, and increased by decreasing the fuel or with increased carbon-monoxide in the escaping gases.

This type of blower has been sometimes set to discharge downward instead of upward, under the idea of supporting the weight of the impeller by the back-pressure of the air. It will be noticed, however, that while the impeller lies flat, the pressure when high might approximately balance its weight, yet in the

| Number of Blower. | | | | | | |

| (e) Weight of blower..... | 3,000 | 5,500 | 8,400 | 12,500 | 20,000 | 27,000 |
| (f) Corresponding furnace dimensions at tuyeres, inches..... | 33 by 33 | 36 by 48 | 36 by 81 | 42 by 120 | 48 by 144 | 48 by 192 |
| (g) Horse power at 2 lb. per sq. in..... | 20 | 25 | 43 | 63 | 84 | 100 |
| (h) Horse power at 1 lb. per sq. in..... | 10 | 12½ | 21½ | 31½ | 42 | 50 |
| (i) Capacity of furnace (silver-lead)..... | 42 | 52 | 89 | 131 | 137 | 208 |
| (j) Capacity of furnace (copper-matting)..... | 63 | 78 | 136 | 196 | 250 | 317 |

and, with a pressure of 2 lb. per square inch in lead smelting (g), and of 1 lb. per square inch in copper matting (h). The sizes given are intended to cover the range of lead and copper smelting for fair sized furnaces. In connection with each size is given: (a) the theoretical amount of air displaced and propelled forward at each revolution of the driving pulley. In this no allowance is made for 'slip', or leakage of air backward. Since the surfaces or joints are those of rolling contact, such loss by slip is considerable, especially at high pressures and leakages with the pressure carried. In a large blower the length of such joints may be 20 to 30 ft., and cannot fail to cause some slip. As at present made, however, the joints, or surfaces of contact, are extended, so that leakage is minimized. (b) While the speeds given in the table are the ordinary ones for constant duty, they can be increased to deliver air much in excess of that specified. (c) The capacity given is the theo-

vertical position it would be about one-third only of what it would be when flat, thus causing serious variations of pressure upon the bearings. With upward discharge a similar variation occurs, but it would be in the direction of gravity, so that the percentage variation would be less. It would seem to be well to conform to ordinary practice, which favors upward discharge, and certainly promotes quiet and regular running.

It is well to cover the suction-openings with coarse wire-netting to prevent the entrance of foreign objects into the blower. This precaution is, however, often neglected.

Foundations of a blower generally include a pit underneath, intended to permit a freer entry of air, and to make the machine more accessible for examination. It will be observed that, even if the precaution be neglected, there still remains a sufficient space for the entrance of the air.

HORNSILVER DISTRICT, NEVADA.

By F. L. RANSOME.

*The town of Hornsilver, which came into existence in 1907, lies in Esmeralda county, Nevada, 26 miles south-southwest of Goldfield, 14 miles south-west of Cuprite, a station on the Las Vegas & Tonopah and the Tonopah & Tidewater railroads, and 12 miles southeast of Lida. Mining in this vicinity is not wholly recent, and an earlier settlement on the site of Hornsilver was known as Lime Point. Prospecting of this region began about 1868, and over 20 years ago ore was hauled to a mill near Lida from the Grand Central and other claims near Lime Point; but most of these claims had long been abandoned when the growth of Tonopah and Goldfield called attention anew to this part of Nevada and provided better facilities than formerly existed for its economic development. Work on the Great Western vein began in 1905, and the Grand Central was relocated early in 1908, after the presence of rich ore in the Great Western had been established. The following notes are based on a visit of a day's duration in June 1908. At that time there were about 500 people in the district and considerable prospecting was in progress in the hills west and south of the town. Water was hauled from a spring 12 miles away and supplies were brought from Goldfield by wagons or partly by rail by way of Cuprite. One mine only, the Great Western, was shipping ore.

Hornsilver, at an altitude of 5900 ft., lies on a gentle alluvial slope, which opens northward into one of the broad desert valleys of the region and is inclosed on other sides by hills rising from 500 to 1000 ft. above the town. The rocks of the district are limestone and calcereous shales, which are intruded and in places more or less metamorphosed by masses of granite. The stratified rocks are mapped by S. H. Ball¹ on his reconnaissance map as the Prospect Mountain limestone,² of Cambrian age. He described briefly³ the rocks of Slate Ridge, south of the new town, and shows that these old stratified rocks are continuous with the more metamorphosed beds at Tokop and Gold Mountain, southeast of that ridge. Near Hornsilver some shale is interbedded with the limestone, but a considerable thickness of shale with subordinate calcereous beds underlies fairly massive limestone, which is exposed in the hills south and east of town. The ores lie mainly in these shales.

The principal veins are southwest of town, within a distance of a mile. They constitute an approximately parallel system and cut across the bedding of the shales with a prevailing strike of N. 55° to 66° W. and with steep dips. Although the wall rock is generally shale, the veins are parallel to some fine-grained and rather obscurely exposed dioritic dikes. The two principal veins are the Great Western and Grand Central, which are about a quarter of a mile

apart, the Grand Central being the farther from town. These have been traced by trenches and pits for distances of 3000 to 4000 ft. along their not very conspicuous outcrops. There are also three or four other veins on which less work has been done. All of the vein material that could be seen in 1908 was thoroughly oxidized and for the most part soft. The fissures after being filled with quartz and sulphides evidently had been crushed by later movement along the original dislocation and the vein was thereby rendered permeable to oxidizing solutions. The valuable constituents are native gold and chloride of silver.

The Great Western mine at the time of visit was developed to a depth of 200 ft. and equipped with a 15-hp. gasoline hoist. The 100-ft. level was about 600 ft. long and the 200-ft. level about 175 ft. long. Since that time a 300-ft. level has been opened. The gross product of the mine in June 1908 was, according to the owners, between \$30,000 and \$40,000, the shipments ranging in assay value from \$75 to \$400 per ton. The Great Western vein strikes N. 60° W. and near the shaft dips 50° N.E. At the northwest end of the 100-ft. level, however, the vein is nearly vertical. There is a very regular and persistent hanging wall with a thin skin of soft gouge separating ore from country rock. The vein is in some places about 20 ft. wide and consists of the usual crushed rusty quartz found in the veins of this district. Much of this material is said to yield assays of about \$30 per ton, but only the higher-grade portions have been stoped. The ore from these portions shows abundant cerargyrite as sparkling olive-green crusts on the rusty quartz fragments and as small crystals in spongy limonitic material residual from the oxidation of the original sulphides. Minute quantities of a bluish-green mineral in thin crystalline rosettes associated with the cerargyrite are probably embolite or bromyrite, but have not been chemically tested. The ore shipped in 1908 contained relatively little gold; not more than 15% of the total value of the precious metals present. Recent reports, however, indicate that ore with a much higher proportion of gold has been stoped in the northwestern part of the 200-ft. level. A second vein has been cut near the shaft on the 100-ft. level, samples from which are said to contain more gold than silver. It had not been stoped at the time of visit. In January 1909 the mine was reported to be shipping 12 tons of ore per day by way of Cuprite.

A short distance southeast of the Great Western mine the vein passes under alluvial material and little is known of its extent or value in that direction. It has been traced northwestward, however, for 3000 ft. or more, and several sets of lessees were engaged in 1908 in exploring this vein or others in the same general zone of fissuring. No work was in progress on the Grand Central vein in June 1908, although some shipments have since been reported in the mining press.

About 1½ miles due south of Hornsilver, on the other side of the limestone ridge (Slate Ridge), which separates the town from a small arm of Death valley, known as Oriental Wash, is the Redemption mine, worked superficially many years ago and recently re-opened by lessees.

*Abstract from Contributions to Economic Geology, 1908. Bull. 380, U. S. Geological Survey.

¹A geologic reconnaissance in southwestern Nevada and eastern California: Bull. U. S. Geol. Survey No. 308, 1907, Pl. I. ²Now known as the Eldorado limestone. ³Op. cit., pp. 182-195.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Eclogite is a metamorphic rock consisting mainly of red garnet, augite, quartz, hornblende, and kyanite, the relative abundance being in the order named.

Granulite is a crystalline rock occurring associated with gneisses, supposed to be altered from an igneous rock. Granulite usually contains an excess of orthoclase, with quartz, garnet, and mica. When pyroxene is the predominant mineral it is called pyroxene-granulite.

Choke-damp is the gas resulting from the explosive combustion of 'fire-damp', that is, a mixture of various hydro-carbons evolved from coal. The 'choke-damp' is mainly carbon dioxide, although some carbon monoxide may also be formed, depending upon the proportion of hydro-carbons in the atmosphere of the mine at the time of explosion.

Turquoise has no steady market at a fixed price. Owing to its variation in quality fixedness of value would be impossible. Average turquoise contains only about 10% of the mineral of a grade suitable for even crude jewelry. Such material commands about 25c. per pound in the Eastern markets. Better grade rock will bring as much as \$3 per pound. High-grade rock, of true robin's-egg blue, sells by the piece, according to size and quality.

Kyanite or cyanite (a name derived from the Greek *Kyanos*, dark-blue) is a basic metasilicate of alumina. It occurs chiefly in gneiss and in mica schist, and was evidently formed at a moderate temperature, since on heating it above 1300°C. it is changed to fibrolite. It is only accessory mineral in rocks, though it is characteristic of some of them, as for instance the granulites. Fine specimens have a value as gems, but these are rare. Its specific gravity is 3.56 to 3.6, and its hardness 5 to 7. It is blue, white, gray, green, and even black. It is often associated with corundum.

Check-holes in placer-drilling cannot necessarily serve to make an actual check upon the individual holes previously drilled, but as a means for proving whether the value of the placer-ground as a whole was accurately estimated. If desired to follow closely the results of the original driller the check-holes may be placed close to the earlier ones. There is danger, however, of obtaining false results in the check-holes if placed only a few feet distant, owing to possible disturbance of the ground through boulders which had been pushed out of the path of the casing. The original driller may have obtained extravagant results by sand running in from the sides, in which case the original sample would be too high and the check-sample too low. In general it may be said that the check-holes should be as much as 5 to 10 ft. distant to be wholly reliable.

Roads built upon a mining claim which can be shown to be a necessary convenience for development of the contained mineral-deposits are accepted

as assessment work. Any buildings which are distinctly required for mining operations, such as hoist-engine house, blacksmith shop, and the like, will also apply, but dwelling houses do not. Such structures, built for the personal convenience of a claimant will, however, possess value as evidence of good faith in case of dispute over ownership.

Bromo-cyanidation is not at present practiced in the United States or Mexico. It was used successfully on an arsenical gold ore at Del Oro, near Marmora, Ontario, for many years, the ore consisting almost wholly of quartz and arsenopyrite, the gold being associated chiefly with the mispickel. The process consisted in stamp-milling, with amalgamation, concentration by jigs and Wilfley tables, with subsequent bromo-cyanidation of the concentrate. The latter was then roasted in revolving cylinder-roasters to recover the arsenic, which was refined on the spot. The cinder after roasting, containing ferric oxide and silica, assayed about \$4 gold per ton.

Mica is a general name for a large group of minerals of which only two, however, are of any considerable economic importance. These are muscovite, the potassium mica, and phlogopite, a magnesium, nearly iron-free mica. The first is known in the trade as 'white mica', and the second as 'amber mica'. Muscovite occurs in quantity and is mined at various points in the United States. Phlogopite is generally imported, being derived from Canada and Ceylon. It is in especial demand for insulation between copper bars of commutator segments. The 'amber mica' wears down evenly with the copper segments, while ordinary or muscovite mica does not wear down so rapidly and is left in ridges above the copper, causing the motor to spark. The principal use of all the micas is in the manufacture of electrical apparatus. Many forms of dynamos, motors, induction apparatus using high voltage, switchboards, lamp sockets, etc., contain sheet mica. Much of the mica used in electrical apparatus is first made up into large sheets of mica board or 'micanite'. Considerable of the finest grades of mica is used in making windows for coal, gas, and oil stoves, lamp shades, decorated boxes. Scrap and ground mica are used in the manufacture of wall papers, lubricants, fancy paints, and, mixed with shellac, in making molded insulators for wires carrying high potential currents. The large electric companies mainly control their own supply. The Westinghouse company has mines in South Dakota. In 1908 the production of sheet mica in the United States was 972,964 lb., valued at \$234,021; scrap mica 2417 lb., \$33,904. Prices of selected sheets in New York ranged from 87c. for the 2 by 2-in. size to \$6.75 for 6 by 8-in. Imports were 548,373 lb., with a total value of \$266,058. Canada produced 580,195 lb., valued at \$198,839, in the same year, and Ceylon, 42,600 lb., worth \$4935, in 1907. Both production and imports in the United States were below normal in 1908, owing to the depression of the manufacturing industry. The duty on manufactured or rough mica is 5c. per pound and 20% ad valorem; on mica cut or trimmed, mica in plates or manufactured forms, 10c. per lb. and 20% ad valorem.

American Mining Congress Program.

The following is the advance program of the Twelfth Annual Session of the American Mining Congress, Goldfield, Nevada, September 27 to 30, and October 1 and 2, 1909.

The convention will be called to order at 2 o'clock p. m. in the Hippodrome, corner Columbia Ave. and Miner St., by Joseph H. Hutchinson, chairman of local executive committee.

Invocation, Rev. James B. Dermody.

Address of Welcome, Charles S. Sprague.

Address of Welcome, George D. Pyne.

Address of Welcome, Denver S. Dickerson, Governor of Nevada.

Response by J. H. Richards.

Five minute responses as follows:

Alaska—Charles Estmere.

Arizona—F. J. Elliott.

Arkansas—A. W. Estes.

Canada—H. H. Lang.

California—E. H. Benjamin.

Colorado—E. A. Colburn.

Illinois—J. A. Ede.

Idaho—Harry L. Day.

Kansas—T. J. Vest.

Missouri—E. R. Buckley.

Mexico—P. J. Tehaney.

Montana—F. H. Cooney.

Nebraska—George W. E. Dorsey.

New Mexico—Arthur K. Adams.

Oklahoma—C. N. Gould.

Oregon—J. Frank Watson.

Ohio—C. O. Bartlett.

Pennsylvania—Samuel A. Taylor.

South Dakota—T. J. Grier.

Texas—M. B. Parker.

Utah—John Dern.

Washington—L. K. Armstrong.

West Virginia—H. M. Payne.

Wisconsin—E. C. Holden.

Wyoming—M. N. Grant.

Report of Committee on General Revision of Mining Laws: W. R. Ingalls, New York City.

Report of Committee on Standardization of Electrical Equipment Used in Mines: Edward B. Rosa, Washington, D. C.

Report of Committee on Revision of Alaskan Mining Laws: J. L. Steele, Landlock, Alaska.

Report of Committee on Vertical Side Line Law: George W. Riter, Salt Lake City, Utah.

Report of Committee on Coal Tax Insurance Fund: Samuel A. Taylor, Pittsburg, Pennsylvania.

Report of Committee on Prevention of Mine Accidents: H. H. Stoek, Scranton, Pennsylvania.

Report of Committee on the National Forest Service: A. G. Brownlee, Denver, Colorado.

Address: Francis G. Newlands, Senator from Nevada.

Address: Charles Dick, Senator from Ohio.

Address: George A. Bartlett, Congressman from Nevada.

The Mines of Nevada: E. E. Stuart, State Inspector of Mines, Carson City, Nevada.

The Round Mountain District: J. P. Loftus, Goldfield, Nevada.

The Purchase of Coal by the B. T. U. Method and Some Practical Questions in Connection Therewith: Samuel A. Taylor, Pittsburg, Pennsylvania.

Comstock Days: William C. Ralston, San Francisco, California.

The Zinc Mines of Southern Nevada: Douglas White, Los Angeles, California.

The Bullfrog District: Clay Tallman, Rhyolite, Nevada.

The Ely District: Samuel Belford, Ely, Nevada.

Pioneer Mines: Oscar J. Smith, Reno, Nevada.

Mining in Alaska: James Wickersham, Fairbanks, Alaska.

The Manhattan District: C. R. Evans, Manhattan, Nevada.

Application of Steel in Mining Operations: R. B. Woodworth, Pittsburg, Pennsylvania.

The Mining Man's Interest in Land Classification: George Otis Smith, Director U. S. Geological Survey, Washington.
Smelter Rates: James H. Fox, Seattle, Washington.

The Paralysis of Mining Districts: E. B. Kirby, St. Louis, Missouri.

Electricity—Its Relation to the Mining Industry (illustrated with lantern slides): I. B. Potter, Goldfield, Nevada.

A Federal Bureau of Mines: D. W. Brunton, Denver, Colorado; W. F. Englebright, Nevada City, California.

Recent Developments in the Production of Copper: Samuel Newhouse, Salt Lake City, Utah.

The Need of a National Laboratory for Research in the Domain of Operative Mining: Thomas F. Walsh, Denver, Colorado.

The Future of the Copper Mining Industry: H. J. Stevens, Houghton, Michigan.

The Movement for Greater Safety and Efficiency in Mining (illustrated with lantern slides): J. A. Holmes, Washington, D. C.

Federal Land Policies as they Affect the Mining Industry: W. B. Heyburn, Senator from Idaho; Reed Smoot, Senator from Utah; George Chamberlain, Senator from Oregon.

Mine Inspection: Courtenay De Kalb, San Francisco, California; Harry Lee, Salt Lake City, Utah; Joseph A. Holmes, Washington, D. C.

Means for Bringing about a Greater Use of Silver with a View to Reducing the Rate of Exchange between this and Silver Using Countries to the End that Oriental Markets may be Opened to American Manufactured Goods: Moreton Frewen, London, England; James J. Hill, St. Paul, Minnesota; John Hays Hammond, New York City; C. C. Goodwin, Salt Lake City, Utah; A. Heckman, New York City.

Insurance and Mine Accidents: Samuel A. Taylor, Pittsburg, Pennsylvania; Glenn W. Traer, Chicago, Illinois; John H. Jones, Pittsburg, Pennsylvania; David Ross, Springfield, Illinois.

The Mining Stock Exchange as a factor in the development of the Mining Industry: A. B. Ruggles, San Francisco.

Mining as the Basis of National Wealth and the Growth of Modern Cities, Herman Zadig, San Francisco, California.

The sessions of the Congress will be held in the Hippodrome, corner Columbia Ave. and Miner St., three blocks north from the Goldfield Hotel, which will be the headquarters of the delegates.

The Mineral Palace, corner of Main and Miner St., contains a most comprehensive and typical exhibit of the minerals of Nevada and a few smaller exhibits from adjoining States. The formal opening of the Mineral Palace will take place on the first day of the convention.

Wednesday, September 29, will be spent at Tonopah, Nevada, to which a special train will convey the delegates, leaving Goldfield at 8:30 a. m., stopping for an inspection of the large stamp-mill at Millers Station and the larger mines of the Tonopah district. At 3:30 a business session will be held at which the general subject of mine inspection will be discussed. A short business session will be held in the evening, after which the special train will return with the delegates to Goldfield.

It is planned to devote the greater part of Tuesday to a discussion of the silver question; Thursday to the question of General Revision of Mining Laws; Friday to the Land Policies of the Federal Government as they affect the Mining Industry, and it is proposed to devote whatever time may be necessary for a thorough discussion of these subjects. Technical and descriptive papers will take second place to the practical discussion of live subjects upon which the action of the Congress is expected. Saturday will be California Day, in which special delegations from that State will participate. The Congress will be officially adjourned at noon on Saturday, after which an opportunity will be given to examine the mines and mills of the district.

The Goldfield Entertainment Committee will provide entertainment for every moment not otherwise occupied, but will not interfere with the regular business sessions of the Congress. Provisions have been made for a rock-drilling contest open to the world on Saturday afternoon, and for a street carnival to be known as 'The Malapai Mixup,' on Saturday evening.

Publications Received.

*Any of the books noticed in these columns are for sale by or can be procured from, the MINING AND SCIENTIFIC PRESS.

BENEFICIO DE METALES DE PLATA Y ORO POR CIANURACION.
By Ferdinand McCann. 8vo., pp. 404, ill., index. Published by the author, 1909. Price \$5 U. S. Cy.

Technical treatises in Spanish, dealing with the latest advances in metallurgy are few, and each one that appears commands particular attention. It is peculiarly fitting to have a manual of cyanide practice emanating from Mexico. The sudden looming up of an adaptation of cyanidation to silver ores in Mexico has developed a new phase of the art. It seems strange that for so many years the presence of silver in considerable quantity in an ore had been deemed a deterrent against cyanidation, whereas today this solvent has revolutionized the metallurgy of complex silver ores. The three cardinal points, of course, are fine grinding, sufficient strength of the solution, and economical methods of agitation. While the Pachuca tank was not invented until recently, the air-lift and the tube-mill were available 15 years ago, and a tube-mill was specified for a Mexican silver plant as early as 1898, but was left out because of the timidity of the mine-owners. The development of the Mexican cyanide practice was a case of evolution; the time was ripe for the adoption of the several means that would lead to the desired economic end, and the ideas cropped up suddenly in so many places that it is evident that the winds of progress had widely scattered the spores; squabbling over priority is therefore of little avail. Mr. McCann has essayed a chronology of the cyanide process, which would be interesting if verified; it is the one part of his book which we would criticise adversely; it can do no good, and the vacuum process has developed acute neuropathic symptoms among a considerable group of otherwise healthy gentlemen. The treatise before us is not a book made just to sell; it is a serious manual, entering into all the details of theory and technology, written exclusively in the Spanish language. A feature of the work which is of special interest is a series of nine chapters devoted to details of practice at the leading Mexican plants, such as Dos Estrellas, El Oro, Esperanza, Guanajuato Consolidated, Real del Monte, Coscotitlán, San Rafael y Anezas, and others. These chapters are very complete, and give consumption of supplies and costs distributed in many cases to the various operations in great detail. There is a large folded table giving such minutiae, in comparison with Black Hills practice, prepared by W. E. Hindry. Favorable comment is made, and much space given, to the electric precipitation process of S. B. Christy, accompanied with the explanation that as the double cyanide of zinc and potassium is not a good solvent for silver, electric precipitation offers a hopeful means of avoiding the introduction of zinc into the solution. An appendix gives an elaborate conversion-table for ounces into kilograms, from 1 oz. to 1000, together with a conversion-table for Troy ounces per avoirdupois ton to grains per metric ton, and vice versa. The book is valuable for the new and interesting data it contains, and will be particularly useful to those desiring an acquaintance with all the terms applicable to this industry as an aid in superintendence of Spanish-speaking assistants.

It is likely that a plant for the extraction of minerals by a chemical process will be erected in Butte. The inventor is Charles S. Bradley, of New York. Albert C. Burrage, of Boston, an Amalgamated Copper company director, is associated with him and is financing the project. Mr. Burrage and Mr. Bradley were in Anaconda last week to make an inspection of the leaching process used by the Amalgamated company in treating the tailing dump at the Washoe smelter. The Amalgamated is able to save only about 80% of the mineral content of the Butte ores and 20% is lost with the tailing, of which there are millions of tons about the big Washoe smelter. The company is trying to save some of this mineral by a leaching process but, it is understood, is able to recover only about half. Bradley and

Burrage shipped a carload of the tailing to a small chemical plant they are operating in the East and claim to have saved 90%. They are now trying to get a contract from the Amalgamated company for the exclusive right to handle the Washoe tailing.

A New Muffle-Furnace.

A compact, self-contained, and convenient muffle-furnace, using gas for fuel, has recently been put on the market by the Denver Fire Clay Co., Denver and Salt Lake. It will appeal to assayers because of the fact that it is possible to maintain a uniform heat as high as 2100°F. with a gas consumption of only 150 cu. ft. per hour. The furnace is supplied with the Case patented gas-burner, enabling any

kind of illuminating gas to be utilized. The blast is supplied by a small fan direct-connected to an electric motor, which latter consumes about as much energy as a 16-candle-power lamp. The muffle is 10 by 16 in., and will hold fifteen 20-gram crucibles. It may be removed and replaced without disturbing any other parts. The company has issued Bulletin No. 26, describing this furnace, which it will send to any address.

Commercial Paragraphs.

The LUCAS PUMP Co., Dayton, Ohio, has elected John W. Good treasurer, to succeed R. E. de Weese, resigned.

The ALLIS-CHALMERS Co., Milwaukee, has received a contract for a large pumping engine to supply water for the city of Wheeling, West Virginia. It is to be of the triple-expansion, crank and fly-wheel type, and will have a capacity of 20,000,000 gal. per day. The low-pressure cylinder will be 110 in. diam. and have a 72-in. stroke. The total weight of the engine will be over 1100 tons.

THE GALIGHER MACHINERY Co. is, as was briefly noted in this column last week, the new name of the Utah Mining Machinery & Supply Co., of Salt Lake City, Utah. The company was organized in 1902 with a capitalization of \$100,000. With the re-organization which is effective September 9 the capitalization is increased to \$600,000, one-half of which is preferred stock and the other one-half common stock. The officers of the new company are the same as those of the old, that is, E. F. Holmes president, J. E. Galigher vice-president and general manager, W. W. Armstrong treasurer, and A. J. Lowe secretary.

EDITORIAL.

RECENTLY a convention was held in Sacramento to consider the damage alleged to be done to streams and riparian farms by dredging on certain central California rivers. A committee was appointed, consisting of Messrs E. B. Edson of Knight's Landing, Jesse Poundstone of Grimes, Louis Tarke of West Butte, William Beckman of Sacramento, H. H. Dunning of Marysville, and Dr. B. Caldwell of Biggs, to investigate. The finding of the committee fails to sustain the contention of damage from dredge-tailing as the work is now conducted—even the dredgers on the Yuba river, that had been severely criticised are released from blame. In conjunction with the testimony of Captain Jackson and other engineers of the Débris Commission, this report should terminate agitation against the dredge operators in California.

THE COLORADO School of Mines, at Golden, Colorado, has prepared plans for an experimental ore-dressing and metallurgical laboratory, suitable both for instruction and for commercial testing of ores. The plant will be promptly erected, and will serve a most useful purpose. From the design it appears that a great range of work will be possible. Apparatus representing different types and methods will be provided, so as to illustrate varying principles. We note that the ordinary stamp battery is supplemented by Nissen stamps; that rigid and spring-rolls stand side by side; that eight different forms of table and belt concentrators are included; that a portion of the mill is set apart for dry concentration; and that there is an elaborate cyanide division, including a tube-mill. Congratulations are due to Mr. Victor C. Alderson, president of the School of Mines, for the efforts which he has made to provide that institution with so practical an addition. It will mean much for the efficiency of the school, and will benefit the State in high degree.

COMPLIMENTARY and well deserved resolutions were passed by the Board of Geological Survey of Michigan on the occasion of the recent resignation of Mr. A. C. Lane, for twenty years State Geologist. It was pointed out that Mr. Lane's administration had been unprecedented in length and unparalleled in the number of reports published. And that it had furthermore been marked by uninterrupted harmony. Twenty years is a long time in the professional work of one man though a short one in the industrial history of a State. It speaks well for the State Survey that in that period new copper lodes have been located, coal production has increased from 50,000 tons to 1,500,000 annually, rock salt has come to be mined, and the soda mineral

water, limestone, cement, and clay industries have greatly expanded. A mere recital of the progress attained is an excellent argument, if one be needed, for geological surveys, as well as a tribute to the retiring State Geologist. Mr. R. C. Allen, who succeeds to the position, is a younger and less well-known man, but one of excellent training and reputation. The Michigan survey has been served by some of the best American geologists, Alexander Winchell, T. B. Brooks, Raphael Pumpelly, Carl Rommiger, C. T. Wright, and others. It has contributed substantially to science as well as to the development of the State.

IN the shadow of death from an accident, emphasizing the peculiar perils of the miner's life, the American Mining Congress began its twelfth annual session at Goldfield. By a sudden collapse of the Hampton stope of the Goldfield Consolidated mine, three men were entombed, and strenuous deeds of rescue-work were witnessed, too late, as it happened, to be of any avail. A drift was driven through solid rock a distance of 35 feet in 36 hours—a marvellous achievement. The rescuers 'worked like demons', so run the reports, not even pausing to allow the powder-smoke to clear away, and handling the broken rock by shovels, disdaining the use of cars. Such ardor is beautiful; it is inspiring; it deserves praise; it is right! It is an expression of universal brotherhood; yet in the face of these earnest efforts to relieve those who are in peril of death, the thought comes that a little more sympathy and sacrifice to help those who live and move among their fellows entombed in misery that crushes their hearts, would be a still more inspiring spectacle. There is a certain irony in these sudden enthusiasms of human effort to just save a man physically alive—but we have to call them heroic.

GROWING out of a trivial dispute, which a little tact might easily have averted, a labor strike suddenly flashed upon Butte, Montana, momentarily threatening to tie up all the great mines, and to shut off the supply of ore from the smelters at Anaconda and Great Falls. On Friday of last week only twenty per cent of the mines were working, and the inevitable 'gun' in the hands of reckless enthusiasts was menacing the peace of the community. A majority of one of the Engineers' Unions seceded from the Western Federation of Miners and organized an independent association. The answer to this gage was the refusal of the miners belonging to the Western Federation to work in mines employing the secessionist engineers. The strike was settled on Monday by capitulation on the part of the engineers. The difficulty was unique in that no question was at issue between the workmen and the mine-owners. It was a family broil, now happily concluded without precipitating a costly and disastrous closure of the great industry on which Butte depends. The mine-operators of Butte have long shown peculiar consideration to their operatives. To have caused financial embarrassment through inability to adjust their own differences, the workers might have sacrificed the advantages they had previously gained.

ELECTRICITY is being more and more substituted for steam in mining operations, and in many situations notable economies result. At the Butte-Balaklava the saving is estimated at more than 60 per cent. At the Tucson mine in Leadville it is reported at over 70. These great savings are possible because of the high cost of steam in isolated plants. In Colorado, temporarily, there is more power available than the market demands. The completion of the Shoshone plant and the building of transmission lines of the Central Colorado Power Company has made electric power available in Lake, Summit, Clear Creek, and Gilpin counties at a time when for various reasons mining is less active than usual. The cheapness of the new power is a not unimportant influence in the mining revival which is beginning in these old districts. Incidentally it is interesting to know that a recent comparison of rates shows that, for the smaller installations, this electricity developed by water power and transmitted a hundred miles or so across the mountains is being sold at approximately the same rates as by the Commonwealth-Edison Company in Chicago, where the electricity is steam-generated from coal hauled a hundred miles across the prairies. This is one way of removing mountains.

American Institute Meeting.

Not often is it possible for the members attending a session of the American Institute of Mining Engineers to pass in review so large a number of interesting mining and metallurgical centres as upon the itinerary connected with the ninety-seventh meeting held at Spokane, Washington, September 27 to 30. In the West the party is enabled to visit Butte, Anaconda, Wardner, Spokane, Seattle, Tacoma, Salt Lake City, Tintic, and Pueblo. A more varied program for men interested in mines and smelting would be difficult to arrange. The subjects for discussion at this meeting are of peculiar value. We have pleasure in publishing an abstract of the presidential address by Mr. D. W. Brunton, in this issue. It is one of those eminently useful papers in which a man competent to measure the present state of the art gives a picture of progress. We note with interest that the question of professional ethics, which we have so strenuously insisted upon, will come forward for consideration. The American Institute of Mining Engineers has deliberately held aloof from formal pronouncement upon all problems, technical and general. The judgment of the venerable and distinguished leader of the Institute, Mr. Rossiter W. Raymond, is against such procedure, and that field of usefulness is therefore closed to the society. We have threshed out this straw with Mr. Raymond in the past, and we are convinced that he has made up his mind to have his way about it. We are sorry, for, if he only knew it, we see so many ways in which the Institute might have blazed the path toward higher ideals—and Mr. Raymond excels in ideals—and have guided the profession by an authority whose fiat would have been recognized. The present meeting will be a memorable one in many ways. It is perhaps another heresy to suggest that the Institute and the American Mining Congress, both meeting on identical dates in

Spokane and Goldfield respectively, might have bowed to each other—just a stiff, distant, little nod, if nothing more. Each might thereby have been the gainer.

The Mining Magazine.

The first number of a new monthly periodical, THE MINING MAGAZINE, edited and published in London by Mr. T. A. Rickard, in co-operation with Mr. Edgar Rickard, has just reached us. It is a handsome magazine in every feature. Typographically it is a model of excellence, being printed on high-grade paper, in 10-point machine-set type, and illustrated with handsome engravings. The high character of Mr. Rickard's editing is well known; it has set a world-standard for technical periodicals, intolerant of inaccurate phraseology and clumsy style. He brings experience, gained by long and thoughtful editing of two of the greatest technical periodicals in the world, to the founding of THE MINING MAGAZINE, which occupies a field where it will have no rival. It is devoted to mining as a profession, not to mining as a stock-gambling game. Announcement of the complete detachment of the staff from stock ownership and speculation is frankly and unequivocally made. As always, Mr. Rickard proposes to conserve his independence, and to maintain untrammelled freedom of speech in the interest of the public whom he serves through honest journalism. The new magazine is strong, as might be expected, in its editorial utterances; it is also notable for peculiar breadth and interest in its special correspondence; the articles cover a range of metallurgical and engineering subjects swinging from the Royal Mint in England to South Africa, Australia, America, Spain. The famous Blériot aeroplane is illustrated; Mr. Henry F. Collins supplies a timely paper on 'Sintering of Copper Ores', and Mr. T. Lane Carter tells of metallurgical practice on the Rand. Large space is devoted to company reports; and a review of technologic advance is a welcome feature. The metal markets of the month are reviewed in a manner that casts light before as well as behind; even the man with an opinion has arrived to open 'Discussion' in this initial issue. We may be pardoned for expressing pride in this enterprise, which, if not our child, at least belongs in the family and wears our tartan.

Alaskan Railways.

Railway construction in Alaska is making good progress. Officials of the Copper River road, running from Cordova inland, expect to handle shipments from the Bonanza mine by a combined rail and boat-line this autumn. The Alaska Central, at Seward, is going ahead after a three years' wait. Construction as far as Turnagain Arm is under contract, and expected to be finished by October 15.

Construction in the north is proving to be unexpectedly expensive and harbor problems are proving by no means negligible. It is currently estimated that the Guggenheims are spending a million dollars on their hundred-mile line to the coal-fields. While there is little doubt as to the ultimate utility of these Alaska lines, their immediate future is not certain. It is difficult to see from what source, for

some time at least, sufficient freight will come to pay interest and dividends. Metal mining will necessarily develop slowly. While there is an abundance of excellent coal to be transported the land laws have not been such as to permit of the honest acquirement of tracts large enough to give any single road a monopoly, or even a dominant position. Out of the situation ugly scandals have grown, and much anxiety has come to those attempting to open the country. It is, however, one of the facts which enter into the situation.

Difficulties as to markets also exist. There is no large local demand for coal, and the Pacific Coast cities do not afford an attractive field for coal-selling. British Columbia and Puget sound ports are well supplied from local sources. California has come to depend so exclusively on oil that the market for coal has nearly disappeared. While prices paid are high it would take but a small quantity of coal to break the market. In actual operation approximately three and a half barrels of California oil equal one ton of good coal. There are existing contracts for oil as low as 19 cents per barrel. Most of the oil is now sold at 80 cents to a dollar. Assuming the latter price for the future, coal would need to be delivered at California points at \$3.50 per ton to compete on price alone, and when the many incidental advantages of oil for fuel are taken into account it is evident that coal can not be substituted for it in any large way until the oil fields begin to show signs of exhaustion. When that will come no one may safely predict, but to all appearances it will not be in the immediate future. Coal is sold in California and in the markets supplied from California ports, to small users only, people who do not discriminate as to differences in quality. There is therefore less than the usual opportunity to introduce Alaskan coal on the basis of quality.

Probably the largest immediate market will be afforded by the railways themselves, but an industry, no more than a man, can lift itself by its bootstraps. The steamers running to Alaskan ports will hereafter need only to carry coal on the outbound trip, and can use the Alaskan product coming back. All this, however, will afford but a small market, and the roads as well as the coal mines must depend for their ultimate profit on upbuilding local industries. Fortunately the opportunities for this are good. The recent discovery of apparently valuable gold-quartz veins in the placer districts back of Seward is important and the continued development of the copper deposits even more so. With proper laws, and proper attention, fishing, lumbering, and agriculture, may all come to contribute important amounts of freight, but railway building in Alaska is necessarily pioneer work. It has been in pioneer railway building, however, that Americans have been most successful. A marked characteristic of America's industrial history has been the fact that railways have been built to develop a region rather than to afford an outlet for existing industries. While the way has been strewn with wrecks the results have justified the procedure, and similar results will probably in time justify the building of the Alaskan roads.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

R. C. SHAW is in Los Angeles.
 M. B. HOLT is in New York City.
 ROBERT MITCHELL is in San Francisco.
 A. J. ROBIN is at Cherry Creek, Nevada.
 T. B. BEADLE is in Winnemucca, Nevada.
 EMMET D. BOYLE is in Silver City, Nevada.
 R. H. YOUNG is in East Auburn, California.
 HORACE F. EVANS is visiting San Francisco.
 W. P. CATLIN has removed to Reno, Nevada.
 L. C. TRENT, of Salt Lake, is in San Francisco.
 GERALD GALT has gone to Winnipeg, Manitoba.
 R. J. HAWKE has come to San Jose, California.
 C. A. BOYLE has gone to La Grange, California.
 F. G. LASIER has gone to Crescent City, Florida.
 ALGERNON DEL MAR has gone to Granite, Oregon.
 W. A. ROWLAND has gone to El Portal, California.
 STEWART BLACKBURN has gone to Victor, Colorado.
 J. F. STAYER has gone to Idaho Springs, Colorado.
 T. K. MULLANE has gone to Bonnie Clare, Nevada.
 FRED. M. CARLOCK has removed to Medford, Oregon.
 WALLACE MACGREGOR has gone to Goldfield, Nevada.
 ROBERT LINTON is examining properties in Sinaloa.
 JAMES H. BATCHELDER, JR., is in Socorro, New Mexico.
 F. D. GOODY, of Denver, visited Salt Lake City recently.
 THEO. E. SCHWARZ has gone to Brookline, Massachusetts.
 C. L. CONSTANT, JR., of New York City, has left for Ontario.
 PAUL S. COULDREY is residing in Greenwood, British Columbia.

R. H. FRAZER has left West Point, California, and is now in Berkeley.

W. M. KNOX has returned to San Francisco from Rawhide, Nevada.

WILFRED B. WAINWRIGHT was in San Francisco on his way to Oregon.

WILL WRIGHT will go to Sardinia in October to manage mining properties.

L. D. BISHOP has returned from Denver, Colorado, to Berkeley, California.

SAMUEL DESCHAMPS has returned from Nome, Alaska, to Seattle, Washington.

S. V. TRENT, of the Trent Engineering Co., Salt Lake, has been in the East lately.

HERBERT T. MUZZY has gone from Pittsburg, Pennsylvania, to Los Angeles, California.

W. H. RADFORD has reached New York from a mine examination in the Chocó, Colombia.

F. W. MACLENNAN has returned from Cerro de Pasco, Peru, and is now at Cornwall, Ontario.

THEODORE GROSS, of the London Venture Corporation, has returned to New York from London.

WILLIAM D. O'BRIEN is in San Francisco on a holiday. He will return to Singapore in about three months.

D. C. McDONALD and A. B. COLWELL, of Ely, and FRED. A. EARLS, of Hawthorne, Nevada, were in Salt Lake City last week.

C. COLCOCK JONES reached Seattle September 15 after a two months' trip through the Copper river region of south-west Alaska.

S. S. SMITH, of the staff of the MINING AND SCIENTIFIC PRESS, was married on September 30 to MISS MARY FORGIE, of Berkeley, California.

CURTIS L. KNIGHT, formerly superintendent of the O'Mera mine, near Silver Peak, Nevada, is now with the Ray Consolidated, at Kelvin, Arizona.

General Mining News.

ARIZONA.

COCHISE COUNTY.

The shaft of the Boston-Courtland Copper Co., at Courtland is down 50 ft. Weldon C. Humphries, the manager, is having the shaft sunk on the drill-hole that the company recently completed.—On the Gardner claim, in the Paradise district, the 285-ft. adit has opened a body of lead ore.—The new adit on the Bisbee-Sonora group is in 125 ft. It is the intention of the owners to drive this adit 1200 ft. to get under the cropings on the surface of the claims.—It is reported that operations will be resumed at the Sullivan property.—The matte output of the Copper Queen smelter, at Douglas, was increased 400,000 lb. in September over the August product, the last month approximating 9,000,000. There were eight furnaces and seven converters running throughout the month.—The drift from the 1250-ft. level of the Oliver shaft at the Calumet & Arizona mine opened a rich body of oxide ore. This is several hundred feet deeper than any other known body of oxide ore in the district near Douglas and from the present showing appears to be one of the richest.

GILA COUNTY.

The north cross-cut from the 500-ft. level of the Telfair shaft of the Arizona-Michigan company is in 95 ft. in a hard diorite. The south cross-cut on the same level has been driven 115 ft., and is expected to open the vein shortly.—The power house at the Arizona Commercial property has been completed and all the machinery installed. A new Prescott pump was installed on the sixth level and both sixth and seventh levels are being opened preparatory to stoping.—The cross-cut from the level 450 ft. below the adit which opened the Black Oxide vein at the Superior & Boston property, intersected the same body of ore. The vein is 20 ft. wide at that point, the ore being copper glance, chalcopryrite and hematite.

GRAHAM COUNTY.

George F. Reed and Dell Potter have made several small shipments of copper ore to the Shannon smelter from the Shannon property in the Upper Metcalf district which they are operating under lease.—At the New York-Arizona a raise is being driven from the lower level to connect with the shaft on the Buzzard Shadow claim for ventilation. John Moulder is superintendent.—A body of high-grade ore was opened on the property of the Arizona Commercial company in Gold gulch near Morenci.

MARICOPA COUNTY.

The Interior Mining & Trust Co. is to resume operations at its property near Wickenburg. The roads which were damaged by the recent rains are being repaired and a site graded for a new double compartment shaft which is to be sunk to the 500-ft. level before lateral work is started. F. X. O'Brien is manager. There is a 100-ton Nissen stamp mill and cyanide plant on the property.

MOHAVE COUNTY.

At the Tucker mine, six miles from Hackberry, there are several tons of shipping ore on the dump, and it is the intention of the management to forward it to one of the smelters shortly.—The cross-cut from the drift at the Gold Crown property, in the Union pass district, opened a 23-ft. vein of ore.

PINAL COUNTY.

The Imperial Copper Co. has a crew of engineers in the field surveying a line from the terminus of its railroad at Silverbell to some deep-water point on the Mexican coast. It is understood that the company is trying to secure the concession for the Arizona & Gulf line, a portion of which survey was run several years ago from Cape Lobos on the Gulf of California to the Mexican-Arizona border.—The Ray Consolidated Copper Co. has let a contract for the building of three miles of railroad from its smelter site to the Phoenix & Eastern line. The company expects the work to be completed before the end of the year.

YAVAPAI COUNTY.

The Dunkirk group of the Mount Tritle Copper Co. was purchased by H. R. Ward, of Grass Valley.—After 17 years of litigation the Crowned King mine, in the Bradshaw mountains, was sold by B. A. Turner, receiver, for the Crowned King Mining Co., to the Yavapai Gold, Silver & Copper Mining Co. for \$75,000, of which half was cash, the balance stock in the company. The property, including 18 claims, is equipped with a 20-stamp mill and is credited with a production of \$1,800,000. The company's plans include the erection of a reduction works at Crown King to treat the ore from the Crowned King, Wildflower and Tiger mines. O. Longacre will direct operations at the mine.—A carload of cobalt and nickel ore is being taken from the Red Bluff group in the Black Hills district for shipment to the refinery in New Jersey to determine the value of the ore. T. C. Jordan is manager for the company.—Operations have been resumed at the Leland group in the Big Bug district. The 500-ft. shaft is being re-timbered and the management has contracted for machinery and supplies. Joseph McDonald is manager.

YUMA COUNTY.

The shaft of the Planet mine, at Planet, is down 400 ft. and will be sunk to the 600 before any cross-cutting is done. At that point the vein will be opened to determine if sulphide ore exists below the water level.—The Bowyer Gold & Copper Co. is to open the Swastika group in the Dome Rock range. Joseph Bowyer, of Quartzite, is manager.—J. C. Rutherford and R. R. McDonald are erecting a small mill on their property near Wenden.

CALIFORNIA.

INYO COUNTY.

(Special Correspondence).—The Keane-Wonder mine, managed by Homer Wilson, is producing about 1500 tons per month of ore that assays \$12 per ton, all of which is treated by the 20-stamp mill and cyanide plant on the property. It is stated that an extraction of 95% is made. The mine is opened by four cross-cuts, and a 200-ft. shaft. The ore occurs in lenses within a well-defined zone. It is conveyed from the mine to the mill over an aerial tramway a mile long. The property is on the west slope of the Funeral range, over-looking Death Valley. The main office is at Rhyolite, Nevada, which is the supply centre.

Rhyolite, September 25.

The Bishop Creek Gold Mining Co. is installing a Sullivan compressor and drill at its property on Bishop creek. The compressor will be driven by a 5-ft. Pelton wheel.

NEVADA COUNTY.

The machinery at the Eagle Bird mine, near Maybert, which was recently injured by fire, is being repaired and the company is preparing to re-build the plant.—The 10-stamp mill at the Pittsburg mine, near Nevada City, has been started on ore from the 900-ft. level.

SAN BERNARDINO COUNTY.

At the Jumbo mine, near Hart, the new management has a shipment of \$50 ore ready to forward to the smelter. This was taken from a shaft that has been started in the cross-cut adit. Another cross-cut has been started 150 ft. north of the one that opened the 30-ft. vein.—Cross-cutting has been started on the 400-ft. level of the Oro Belle property, and the cross-cut on the 100 is expected to cut the ore shortly.—William J. Dingee, of Oakland, has acquired 30 placer claims near Johannesburg which contain large nitre deposits. An assay of the ground showed it to contain from 25 to 28% nitre.

SHASTA COUNTY.

G. P. W. Jensen has leased the 4-stamp mill on the Corte group, near Centerville, to Weed & Wickson who are operating near Igo.—The North Witten adit at the Friday-Lowdon property, near Kennett, recently cut a body of copper ore with a fair gold and silver content. S. E. Bretherton, of San Francisco, is manager.—The Shasta County Farmers' Protective Association has retained T. W. H. Shanahan, an attorney of Redding, to represent it in legal dealings with the smelting companies.—The Inca Treasure Gold Mining Co. has attached the property of the Delta

Consolidated Gold Mines Co., on Dog creek, to secure the payment of \$1233 alleged to be due the former company. —The machinery of the Bella Vista Oil Co. is being hauled to the company's property west of Bella Vista. —The Shasta Gold & Copper Mining Co. has been organized to open holdings between the Pit and McCloud rivers two miles north of Heroult.

SIERRA COUNTY.

The shaft at the Gibraltar mine cut the bedrock at a depth of 300 ft. At that point there was a fair amount of gold in the gravel but the owners have turned along the bedrock to get to the bottom of the channel. —The jig recently installed by Jason Fry on his property in Sailor ravine is making a high-grade concentrate which is being sacked for shipment to the reduction works.

TUOLUMNE COUNTY.

Ione Meinert has purchased the Contention mine with water-right and pipe-line in Knight's creek from Calvin F. Summers. —Work has been resumed at the O'Hara mine at Brown's Flat. —A 6-ft. vein has been opened on the Clark Brothers' ranch adjoining the Hazel Dell mine. —The mill at the Soulsby mine is being repaired and the company will soon be milling the rich ore recently opened. —The shaft at the Dutch mine has been re-timbered for 60 ft. —The Draper property was shut down for a few days pending the turning on of the current by the electric company.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence). —A rich find has just been made on the Lost Treasure property, on Columbian mountain. At a distance of 250 ft. from the entrance of the adit a streak of smelting ore has been cut that is 3 in. wide, and assays from 420 to 800 oz. silver per ton, with 20% lead. William Kramer is owner. —Work has been started at the Centennial mine, on Leavenworth mountain. The pumps have been lowered and drifts will be driven west from both the fifth and sixth levels. D. Kennedy, the manager, returned from the East, and it is expected to start work on the new 50-ton stamp mill sometime during the coming month. —Work on the chemical-electro plant being constructed near the Doric tunnel by the Western Metals Co., is well under way. A concrete wall 196 ft. long has been constructed to a height of 12 ft., and millwrights are now at work in framing timbers and in placing them in position. Grading has been started for the second building, which is to cover an area of 180 by 80 ft. The plant will be finished by the first of the year. —At the E. K. C. property, owned and operated by the Geneva Extension M. M. & T. T. Co., a 14-in. vein of smelting ore was cut in the east drift that assays 300 oz. silver per ton. John O'Dea is manager. —H. O. Marcey, of Boston, who recently purchased the Kelly adit holdings on Democrat mountain, has organized a company to drive it 5000 ft. A series of rich silver veins are owned. These will eventually be intersected by the Kelly bore at depths varying from 1000 to 2200 ft. —A number of mine operators in Clear Creek county have entered into contracts with the Modern Smelter Co. for the furnishing of a certain tonnage of ore. This smelter is located at Utah Junction, a short distance from Denver, and although the furnaces have not been started ore is being purchased, sampled and paid for. The first shipment from Georgetown was made by E. J. Butts, who is operating the Columbia property on Silver mountain. Two carloads have been sampled that were settled for at 2.30 oz. gold and 35 oz. silver per ton, with 5% in copper.

Georgetown, September 27.

GILPIN COUNTY.

A new hoisting plant has been completed at the Rockford mine, in the Russel Gulch district. The shaft is now down nearly 200 ft. and has opened a good grade of milling and smelting ore. Sherman Harris is in charge of operations. —The Evergreen Gold Mines & Copper Co. has let a contract to lay 1500 ft. of pipe from the reservoir to the company's mill. F. J. Crane is superintendent. —Operations have been stopped temporarily at the Argo mine in the lower Russel district on account of the heavy flow of water

due to the recent rains. —A new surface plant is being installed at the Hidden Treasure mine on Quartz hill. —A surface plant has been erected at the Gomer mine on the Pendleton-Gomer Mining Co. and the property is being unwatered. The shaft is now down 150 ft., and it is the intention of the company to sink an additional 150 ft. A. A. Johnson, of Denver, is manager. —The East Notaway shipped a carload of smelting ore to Denver last week.

GUNNISON COUNTY.

The dam at the Blaine mill, which was damaged by the ice last spring, has been repaired and the mill will be in operation some time this month. —Several carloads of ore were shipped by the Empress Mining Co. operating on Galena mountain.

LAKE COUNTY.

Regular shipments are being made from the Pearl mine in the Leadville district. The property is being re-opened by Charles J. Moore, of Denver. —William S. Jones is opening the vein of zinc carbonate ore recently cut in the Robert E. Lee mine and is storing the ore for shipment. —Work has been resumed on the Robert Emmet property and the company is preparing to ship 30 tons of ore per day. —The Horrigan Brothers shipped 50 tons of high-grade ore from the Highland Mary mine.

OURAY COUNTY.

The contact vein recently opened at the Antonio property on Red mountain has been driven upon for 60 ft. Assays across the face ran 100 oz. silver per ton as well as several per cent copper. —The ore from the Frank Hough mine, on Engineer mountain, is being packed to Ouray and shipped from that point on account of the washouts on the line between Animas Forks and Silverton. —A carload of \$60 ore was shipped from the Colorado-Eclipse mine.

PARK COUNTY.

The old sampling works at Alma have been remodeled and are again in operation. There is a crew of men at work grading the site for the new smelter, and it is the plan of the company to have it in operation before the end of the year.

TELLER COUNTY.

The air line from the John A. Logan compressor plant to the Pride of Cripple Creek property has been completed and the machine-drills started in the mine. Fred Johnson is superintendent. —S. N. Simmons has opened a vein of \$25 ore on the 180-ft. level of his lease on the Pharmacist mine on Bull hill. A drift has been run 50 ft. along the ore which has been of uniform grade the entire distance. The lessee will commence shipping at an early date. —Thirty tons of ore was shipped by the lessees from the Jolly Tar mine in Victor. The vein is 3 ft. wide, and is found between a phonolite dike and granite. There is considerable sylvanite in the ore which is estimated to run about \$40 per ton. —The Findley Consolidated company has commenced shipping from its lease on the Deadwood mine on Bull cliffs. —A rich orebody has been opened on the 1400-ft. level of the Golden Cycle mine at Cripple Creek. The ore from the 600 to the 800-ft. levels was low-grade but the value seems to have changed with depth as it did in the Vindicator mine. —Sinking is to be resumed at the Dante mine the early part of this month. The shaft is now down to the 730-ft. level, and the company will deepen this another 200 ft. —Edward Cookerly has discovered a 10-ft. vein of ore that assays \$20 per ton at his sub-lease on the Prince Albert mine. The shoot has been opened to a depth of 15 ft. for 30 feet.

IDAHO.

SHOSHONE COUNTY.

Grading has been started on the site for a 100-ton concentrator at the Orofino mine by the Orofino Mining Co. Some of the ore at this property is rich, running as high as 85% lead. This will be shipped direct to the smelter, the rest being concentrated in the ratio of 6 to 1. A lower adit is also to be started to tap the ore several hundred feet below the present workings. Patrick Burke is manager. —The vein which is being followed at the Reindeer property has widened to 18 in. and assays 20% copper. —

At the Rainbow group, southeast of Osburn, a 2-ft. vein of iron-carbonate, copper and silver was opened.—A 300-ton ore bin is being constructed at the Monarch mine east of Murray and the mill is being increased from 75 to 200 tons per day capacity. Work has been stopped in the raise, there being no place at present to store the ore.—A 20-ton furnace, the invention of Maurice Blanchard and C. D. Williams, of Portland, Oregon, is to be erected between Enaville and Enaville Junction, on the line of survey of the Idaho & Northern railroad. A company, known as the North Fork Mining & Smelting Co., is to be organized to operate the plant and to increase its capacity if it proves successful.—A 6-in. stringer of milling galena ore was opened by a cross-cut 100 ft. from the main vein at the Imperial property between Burke and Mullan.—A 300-ft. drift has been run on the property of the Samson Mining Co., on Eagle creek east of Murray, opening a 14-ft. vein of galena ore. The vein has been stripped on the surface for 200 ft. and it will require 200 ft. additional work in the adit to drive it under this portion of the shoot.

KANSAS.

CHEROKEE COUNTY.

A good find of shallow ore was made at Galena, on the Bonanza tract, at the depth of 28 ft. It extended for some distance and at 32 ft. it was estimated that the ore would run nearly 40%.—Buffalo, New York, parties are sinking a shaft on the De Graff land, at Badger, and have indications of ore at 106 ft. Five drill-holes on this land opened three runs of ore from 105 to 195 feet.

MISSOURI.

JASPER COUNTY.

(Special Correspondence).—Among the former properties being brought again into the producing list is the Big Three, west of Joplin. Operations ceased at this large mine some time ago on account of an injunction against it.—Operations have been resumed at the Mercedes, on Center creek. A lower royalty has been granted the company on account of the heavy flow of water.—The Chitwood Bessemer has been taken over by a new company who will reopen it for the pillars. The tailing is being treated in the concentrating plant.—The Old Hickory and Keno mines have been consolidated by J. E. Putman, and are again being operated. A tramway from the Old Hickory will carry the ore to the Keno bins.—The Mercantile Co. is building a new 250-ton mill on a lease north of Webb City.—The Gouverneur Co., on the Excelsior land at Four Corners, has just completed a new 200-ton mill. The company has recently acquired over 1000 acres scattered over the district which they will prospect and sub-lease.—The Tom Cat Co., west of Joplin, has now completed its development having two shafts and several drifts in ore. Work will be stopped until a suitable mill can be erected.—The D. S. & Y. is a new 200-ton plant just completed southwest of Joplin, near the Chicago-Joplin.—Another new plant west of Joplin is the E. J. C. mill near the Kohinoor. A good face of ore has been opened from 100 to 170 ft., running from 10 to 15% zinc. The ground has been well prospected, and a large tonnage of ore stored for treatment at the mill.—Five tailing mills are now working in the Chitwood camp on old tailing piles.—In the Joplin camp a good find of sheet-ore has been made on the Riseling land, the deposit occurring from 123 to 136 ft. The property adjoins the lease held by O. R. Symmes where a rich discovery was made last week.—A good find was made on the O'Keefe land south of Joplin where boulders of almost pure zinc are being taken out, some weighing 400 to 500 lb. There is also a large amount of fine ore mixed with the dirt. At Smelter hill, in sinking the Big Eight shaft, 40 tons of zinc were produced from 56 tons of ore.

Joplin, September 25.

MONTANA.

SILVER BOW COUNTY.

(Special Correspondence).—The death of W. H. Spooner, in Boston, recently, has temporarily delayed the plans for a resumption of work on the Ophir mine by the Butte Central Copper Co. There are two veins in the Ophir, the south one being opened from the 100 to the 500-ft. level. The ore

assays 25 oz. silver and \$2.50 gold per ton, the average in copper so far being around 1%.—Work is to be resumed at the properties of the Butte & New York and Butte-Milwaukee companies. The Butte-Milwaukee is the owner of the Colonel Sellers and Pollock group of claims, and the Butte & New York owns the majority of the stock of the Butte-Milwaukee. The Pollock has been a good silver producer in its time, and there are still large bodies of ore in sight in the mine, which has been worked mostly by lessees. The shaft on the Pollock is a small one and when the Butte & New York people became interested in the Butte-Milwaukee they sank a three-compartment working shaft 750 ft. between two veins which will be opened by cross-cuts when the shaft has reached down 1200 or 1500 ft. The recent discoveries in the Elm Orlu and Blackrock mines have considerably brightened the prospects of the Butte & New York company.—The Davis-Daly company has made temporary repairs at the Colorado, the hoisting engine of which was wrecked two weeks ago, and is operating again. The shaft is now considerably below the 1500-ft. point, and is still being sunk. At the same time development and mining is going on on the 1200 and 1400-ft. levels, the ore shipment being an average of 100 tons per day.—James A. Murray, owner of the fractional Ticon claim, situated in the North Butte group of claims, makes the announcement that he will not bring an action against the North Butte company over the apex of the Edith May vein, and that he has contemplated no such action. This being contrary to statements by his engineers and other statements made by Mr. Murray himself, indicates that a settlement has been made or he has been convinced that his claim of ownership of the Edith May apex is without foundation. The impression in Butte is that the North Butte will soon be announced the owner of the Ticon. The suit brought by the Ticon lessees in behalf of Murray, and with his backing, against the Anaconda company, is still pending in court.

Butte, September 24.

NEVADA.

ESMERALDA COUNTY.

The vein of the Victor claim of the C.O.D. Consolidated Co., has been opened by the cross-cut 90 ft. from the shaft. A dacite intrusion has changed the dip of the vein from vertical to approximately 25 degrees. I. K. Koontz is manager.—The Red Top Mining & Leasing Co. has completed the installation of a new surface plant to replace the one recently destroyed by fire and has resumed development. The raise from the 425-ft. level cut a quartz vein with a considerable copper content.—At the Goldfield Montgomery, six miles east of Goldfield, a 10-ft. vein with 2 in. of high-grade ore has been opened.

LINCOLN COUNTY.

A consolidation of the Nevada Utah and Ohio Kentucky mines at Ploche has been effected and operations have been resumed at both properties.

NYE COUNTY.

(Special Correspondence).—The Johnnie Mining & Milling Co., operating the Johnnie mine, 15 miles south of Amargosa station, is milling 80 to 100 tons of ore per day, the mill having 16 Nissen stamps, amalgamating plates, and a Chilian mill for re-grinding the battery-pulp, all operated by two Fairbanks, Morse & Co. gasoline engines. The operations are now under the superintendency of William A. Farish, Jr., of El Paso, and there are 45 men on the payroll.—Overbury & McMahon have a long-term lease on part of the Tramp Consolidated ground at Rhyolite, through which they will operate on the Eclipse and Hobo veins. A cross-cut has been driven to the Eclipse, and 1000 ft. of drifts run on the vein, opening a good tonnage of ore. A contract has been let for further development. The ore consists of a gold-bearing silicified rhyolite, which is of fair milling grade. A. Sydney Addison, of San Francisco, who is general manager for the lessees, is on the ground testing the ore, and drawing plans for a 10-stamp mill and cyanide plant, which will be erected this fall.—The Montgomery-Shoshone mine and mill, at Rhyolite, are doing well under the management of John G. Kirchen. Financial obligations

of the concern to the amount of \$275,000 have been paid within the last 14 months. The ore, a rhyolite-quartz, runs from \$7 to \$8.50 per ton gold, with 10 oz. silver to \$20 gold. The mill, which is in charge of E. M. Kirchen, is crushing and treating 6000 tons per month. The ore is passed through Blake crushers, followed by sizing and re-crushing through three sets of rolls, and re-grinding in two Monadnock Chilian mills, in cyanide solution. The pulp is then passed to Dorr classifiers, the sand being sent over Wilfey-tables and the slime to vanners. The resulting concentrate is then re-ground in an Allis-Chalmers tube-mill, in cyanide solution, and further cyanided in cone-tanks. The table-tailing is carried to the sand leaching tanks, the vanner tailing to the slime leaching tanks, the latter being provided with L. C. Trent agitators. The gold-bearing solution from the slime tanks is passed through Butters and Blaisdel filters before going to the precipitating tanks. At the mine the work is in charge of George Liles, and ore is being taken from six levels.—The Bullfrog & Mayflower Consolidated Mining Co., in Pioneer district, contemplates adding 15 stamps to its present 5-stamp mill. The mine is opened to a depth of 400 ft., and several lessees are at work. On the Aylward lease, a 300-ft. shaft is being sunk, and no lateral work will be done till that depth is reached.—E. P. Miner, of Rhyolite, has found sulphide ore in a 40-ft. shaft in Indian Springs district, half way between Rhyolite and Pioneer.

Rhyolite, September 25.

WHITE PINE COUNTY.

The Mulligan group of claims of the Boston-Nevada Mining Co., situated 2½ miles from Osceola, is being developed under direction of F. D. Goody, of Denver, who states that the development is by adit levels, and that a discovery of gold and silver ore was made recently.

OREGON.

BAKER COUNTY.

The Keystone Dredging Co. has completed payments on 440 acres of placer ground below Sumpter. The company has obtained options on several tracts of land and will do considerable prospecting to determine the value of the properties for dredging.—An order for 25,000 ft. of lumber has been placed with the Adams-Gardiner Lumber Co. to build a boat for the dredge at Gold Center. The machinery was previously mounted on trucks but these became clogged with the tailing and the company decided to construct a boat. J. B. Wetherall is in charge of the work.—The National Mining & Leasing Co. is installing a tube-mill and slime-filter in its plant at the Cougar mine. The capacity of the mill is 80 tons per day. There is a large amount of ore blocked out in the mine that assays between \$10 and \$20 per ton.—The Highland mine is shipping regularly to the sampling works.—The drift on the 200-ft. level of the Independence mine west of Sumpter opened a shoot of ore that assays from \$34 to \$220 per ton. Walter G. Gleson is manager.

JACKSON COUNTY.

There are 10 men working at the Braden mine which J. W. Dawson is operating under a lease.—At the Lucky Bart mine, in the Sardine Creek district, the owners are blocking out ore and repairing the wagon road.—The new machinery recently ordered for the Gray Eagle mine is expected to arrive any time.—The owners of the Blackhawk mine, at Drummond, are to commence operations shortly.—A 5-stamp mill will be erected at the Trustbuster mine, of W. R. Oxley, in the Sams Valley district within the next two months.

MARION COUNTY.

The vein recently cut at the Black Eagle mine, in the Santiam district, is proving very rich, assays having been obtained running as high as \$400 per ton.

PENNSYLVANIA.

SOMERSET COUNTY.

A unique discovery of vanadium in appreciable quantity was made recently in one of the coal deposits near Rockwood. Details of the new discovery are closely guarded.

UTAH.

BEAVER COUNTY.

J. C. Brownfield has purchased the Pay Day group of claims in the Beaver Lake district from Mell Smith and operations will be resumed at the property within the next two months. There is a 130-ft. shaft and a 100-ft. drift on the ore, which assays from \$80 to \$100 per ton.—A diamond-drill has been installed at the Blackbird mine. J. R. Steele is in charge of the work.

JUAB COUNTY.

The cross-cut to the southwest on the 300-ft. level of the Bullion-Beck mine of the United States Smelting, Refining & Mining Co. opened a body of copper ore of smelting grade.—The shaft of the Tintic Standard is now down 450 ft. The company will sink to the 600-ft. level and cross-cut from that point.—The Iron Blossom, Colorado, and Sioux Consolidated declared dividends of 8c. per share for the two former and 7c. for the latter.—Work has been started on the drainage adit at the Centennial-Eureka from the surface and the 500-ft. level of the shaft. The adit will be 3000 ft. long and save a lift of 500 ft. on the hoisting and pumping. The company is to install a heavier pumping plant owing to the heavy flow of water met in the shaft some time ago.—The shaft at the East Tintic Development Co.'s property, in East Tintic, is down nearly 500 ft. When the shaft reaches that level a station will be cut and laterals started to explore the ore. Six cars of ore have been shipped from the mine lately which have netted the company a profit over all mining and shipping expenses. Ralph Kellogg is manager.—At the Grutli property, in East Tintic, the shaft is down over 190 ft., and has cut the contact on which the orebodies are found. A station will be cut at the 200-ft. level and drifts run along the contact. The company is planning the erection of a power plant and the installation of machine-drills.—The injunction which restrained the Grand Central from operating on the 1600-ft. level has been dissolved and the company is cross-cutting there, to open the orebody found on the lower levels. On the 2000 and 2100-ft. levels a 6-ft. body is being opened that assays 7% copper, 10 oz. silver and \$9 gold per ton.

SUMMIT COUNTY.

The completion of the Ontario drainage adit at Park City has done much to relieve the water trouble at the American Flag property and the shaft has been drained to the 1100-ft. level. There is a large amount of milling ore blocked out in the mine and it is understood that the company is considering the erection of a mill. G. H. Rathman is manager.—A drift has been run 130 ft. on an 18-in. vein at the Silver King mine, the ore from which assays well in copper, lead and silver, with a small amount of gold. The management has ordered a skip and will install it in the shaft in place of the bucket it has been using.—Preliminary work has been started on the Snake Creek-Bonanza Flat-Daly-Judge adit by commencing the surface plant on Snake creek. The completion of this adit will open a large territory of mineral land in the Park City district, and insure good drainage to the mines along its course.

The Iowa Copper company at Park City has started shipping copper ore to the smelter.—The raise from the adit of the Baby McKee mine has opened a 2½-ft. body of ore that assays 8% lead and 75 oz. silver per ton.—On the 260-ft. level of the Uintah Treasure Hill mine a cross-cut is being driven toward the vein.

TOOELE COUNTY.

At the new smelter of the International Smelting & Refining Co., in Pine canyon, 12 of the 32 McDougall roasting-furnaces are complete. The brick flue has been started and the foundation for the stack finished. When completed this will be 320 ft. high. A number of pack trains are busy transporting material from Pine canyon for the aerial tram between the property of the Utah Consolidated and the smelter.—At the Silver Island mine the company is sacking ore for shipment that is worth about \$5 per sack. David Morrison is in charge of the work.

UTAH COUNTY.

A new body of lead carbonate ore has been opened at the

Mountain Dell property, near American Fork. The ore is being sacked for shipment at the mine.—At the Pacific property an orebody has been opened that assays 24% zinc, 15 oz. silver and a small amount of lead.—Operations have been resumed at the property of the Lulu Mining Co., on Deer creek. A 300-ft. drift has been driven along the vein opening a good vein of copper ore.—A contract to drive the adit 150 ft. has been let by the management of the Signet Mining Co. operating at Holman's flat.—The face of the adit at the Mineral Flat property is in a hard black limestone which overlies the ore-bearing porphyry. A 3-ft. vein of high-grade galena ore was recently opened in the mine and it is understood that the company is to commence shipping in the near future. Swan Nelson is superintendent.

CANADA.

BRITISH COLUMBIA.

The company operating the Blue Bird mine, near Ross-

assaying 2800 oz. silver.—Surface trenching on the Mann property at Gowganda opened a calcite vein in which there is from 2 to 4 in. native silver.—A cross-cut on the 120-ft. level on the Nova Scotia mine is being driven to tap the main Bilsky vein. A shaft has been sunk on this ore and at the bottom the vein contains from 3 to 4 in. of smaltite with native silver. The vein has been traced on the surface for 500 ft., and enough ore blocked out to keep the mill crushing at the rate of 75 tons per day for the next four years. R. S. Robertson, of the Peterson Lake Mining Co., has brought suit against the Nova Scotia company to recover \$1,000,000 damages for ore extracted by the latter company from the former's ground and to restrain the Nova Scotia from trespassing on the Peterson Lake property.—At the Temiskaming the crusher-house is nearly completed and the machinery is being installed. The ore will be dumped from the skips to the bins there, and be reduced before it is loaded on the aerial tram for the concentrator. In the mine the company is to sink to the 350-ft. level. The

Steam-Shovel Mining, Utah Copper Mine.

land, is preparing to open the mine on a larger scale. Ore taken from the surface workings of five veins netted the company \$30 per ton on a 10-car shipment.—The British Columbia Copper Co. has bonded three additional claims in the Kamloops district, the Irene, Sunset, and Shamrock. The veins on these claims will approximate \$20 per ton.

There are 80 men working in the Le Roi mine, and a good grade of ore is being stoped on the 600 and 700-ft. levels. The company is also carrying on considerable exploratory work with diamond-drills.—A Minneapolis company has purchased the Blair and Voigt coal claims in the Nicola valley

ONTARIO.

The new cyanide plant at the Buffalo mine in the Cobalt has been completed and is successfully treating the ore from the mine. The ore is ground fine, classified, and cyanided, the slime going to a filter press. The plant has a capacity of 50 tons per day.—S. W. Cohen, manager of the Crown Reserve mine, has been appointed consulting engineer, and John Carson, president of the Crown Reserve, has been elected president of the Silver Leaf company. This tends to confirm the report that the Crown Reserve has bought the controlling interest in the Silver Leaf property.—The Wettlaufer mine in South Lorrain shipped 25 tons of ore

shaft is now down 336 ft. with cross-cuts run at the 300-ft. point.

MEXICO.

CHIHUAHUA.

The Refugio mine, in the Parral district, is being unwatered. Thos. Sheppard, representing A. J. McQuatters, is in charge of the work, and has a force of men cleaning out and re-timbering the shaft. There is a 150-ton mill on the property, erected by Angel Garcia, the former owner. A crew of men is also at work repairing the spur from the Parral & Durango railroad to the mine.—The San Francisco del Oro Mines Co. shipped 500 tons of ore to Wales to determine the best method of treatment. There is a large amount of rebellious ore blocked out in the mine.—The Parral Consolidated Mines Co. has completed the foundations for its new mill on Prieta hill, and is erecting the framework. Several carloads of machinery are on the ground, and the company expects to complete the plant this fall.

COAHUILA.

The Sabinas Coal Co. has placed an order for 60 coke ovens to be installed in its plant at Rosita at an estimated cost of \$300,000.

Special Correspondence.

GOLDFIELD, NEVADA.

American Mining Congress. — San Francisco Delegation. — Mineral Palace. — Cave of Hampton Stope. — Splendid Rescue-Work. — Clermont Shaft. — Combination Fraction. — Daisy. — Diamondfield Black Butte Re-Organization

The twelfth annual session of the American Mining Congress opened in Goldfield on Monday, September 27, under most auspicious circumstances, and with a representative attendance of delegates from all parts of the United States. The San Francisco delegation, over 100 strong, and accompanied by a brass band, arrived in three special cars and did much to enliven the meetings of the congress and to strengthen the good feeling between the people of southern Nevada and the metropolis of the Pacific coast. Among the delegates and visitors from San Francisco who registered at the Mining Congress headquarters on the opening day were: Nat Boas, T. Gottfried, A. B. Ruggles, Herman Zadig, Francis Drake, K. C. Simpson, W. A. Gamont, C. T. Hutchinson, Leon W. Hall, E. O. Shreve, H. H. Haxon, R. M. Mein, Louis Rosenfeld, A. L. Langerman, Henry G. Meyer, William Sexton, E. P. Jones, E. B. Braden, R. L. Dunn, G. B. Lane, T. Rickard, H. F. Gerry, C. W. Wilson, N. Whitehead, W. A. Scott, W. B. Hinchman, J. H. Berghäuser, L. H. Van Wyck, William O'Connor, R. F. Coffin, J. C. Fitzsimmons, J. R. Ferguson, B. F. Shaw, E. Green, P. C. Jurs, G. W. Myers, W. R. Berry, William Bannon, William C. Ralston, E. H. Benjamin, and H. Foster Bain.

While the disastrous cave-in of the Hampton stope in the Combination mine prevented the delegates from seeing that famous portion of the workings, arrangements had been made by George Wingfield and J. H. Mackenzie to show them the Mohawk, and automobiles were placed at their service. A heavy rain during the greater part of the first day kept most of the delegates within doors, but they were afforded every opportunity of inspecting the mines and mills of the district. The town was gaily decorated with flags and bunting, and various forms of entertainment provided for both night and day, closing with rock-drilling contests for large prizes and a street carnival called a 'Malapai Mix-up.'

The first session of the congress was called to order at 2 p. m. Monday, in the Hippodrome by Joseph H. Hutchinson, chairman of the local executive committee, and formerly lieutenant governor of Idaho. Many of the delegates did not arrive until later. The San Francisco train was delayed several hours by a washout, necessitating some changes in the program. Governor D. S. Dickerson, who was scheduled to make one of the addresses of welcome on behalf of the State of Nevada, telegraphed that he was confined to his home by illness, but hoped to arrive before the close of the session. After making a speech in which he paid a high compliment to the San Francisco delegates, Chairman Hutchinson introduced Charles S. Sprague, president of the Goldfield Chamber of Commerce, who welcomed the visitors and who was followed by State Senator George D. Pyne.

J. H. Richards president of the American Mining Congress responded with an impressive address and paid a high tribute to the mining men of southern Nevada and the spirit which had conquered the desert and its hardships, and had built up a great and rich mining community. Edward H. Benjamin, of the Joshua Hendy Iron works, formerly prominent in the California State Mining Association, responded for his State and was succeeded by George W. Hall, mayor of Jerome, Ariz., J. A. Holmes, chief of the technologic branch of the United States Geological Survey at Washington, and E. R. Buckley of Missouri, one of the directors of the congress.

The most interesting feature to many, of the day's program was the formal opening of the mineral palace in which a collection of specimens has been assembled which, according to experts, has not been paralleled in any

state. The exhibit occupies the entire ground floor of one of the largest buildings in Goldfield, and is of great interest from the fact that every mining camp in the state is represented, and not only rich ore is shown but characteristic specimens of low-grade ore and country rock. The last legislature made a generous appropriation to provide for the collection of this exhibit, the greater portion of which will be donated to the Mackay School of Mines in connection with the University of Nevada upon the conclusion of the sessions of the Mining Congress.

The exhibit contains several hundred tons of ore and minerals, and shows in detail the character of the product of every mining camp in Nevada. A feature which is particularly attractive is a long white cabinet, faced with glass, and brilliantly lighted by electricity, which contains the richer specimens. During the last two days of the Congress this cabinet will contain the entire output for a week of both the Consolidated and Florence mills, and it is already an almost dazzling exhibition of gold, silver, and other metals and rare specimens. There are several private collections in the mineral palace, including the Helen M. Schneider collection which has taken numerous prizes at national exhibitions, and was shown throughout Europe. Other collections include that of the State School of Mines, the Loftus-Davis cabinet of Round Mountain and other specimens, and those of W. S. Elliott and Charles F. Kapp.

The disastrous cave-in of the Hampton stope on the morning of Saturday last, in which the lives of three miners were lost, has occupied the attention of mining men in the district to the exclusion of almost every other subject. Aside from the tragedy the loss by the caving of the workings will, it is said, be comparatively slight, although it will result in curtailing the Consolidated company's profits nearly \$60,000 monthly until the new mill is enlarged. It has been the intention of the management to dismantle the Combination mill, as the cost of ore-treatment in this plant has been considerably higher than in the new mill, and it stands over valuable orebodies which will be stoped to the surface. Nine of the large cyanide tanks, filled with 1% solution of cyanide and pulp, were precipitated into the great hole made by the cave, and the lower portion of the plant was completely wrecked. The entire building and equipment will at once be removed. It is probable that steps will be taken shortly to increase the capacity of the new mill on Columbia Mountain to 1000 tons daily.

The management of the Consolidated company is completely at a loss to account for the caving of the Hampton stope. Mr. Mackenzie had gone to the mine at an early hour, and was on the ground when the cave occurred. Mr. Canavan, the superintendent, had reported to Mr. Mackenzie that one of the shift-bosses had told him that the ground at the fifth level had the appearance of caving, and the superintendent immediately ordered all the men in the lower workings to collect their tools and leave the mine. The cave came while some were on their way to the surface, and two or three were struck by flying rocks or thrown against the walls by the concussion of air but none was badly injured. The first cave started above the fifth level and came with great suddenness. Mr. Mackenzie and Mr. Canavan at once descended to the fifth level to make an inspection, and while they were underground the second cave happened, taking the ground above completely to the surface, and leaving a gigantic hole into which a portion of the mill was hurled. Upon reaching the surface, Mr. Mackenzie learned that three miners working at a depth of 130 ft. in a new-cross-cut had not reached the shaft, and at once rescue parties were started to work from two points, the nearest being 35 ft. distant, necessitating a drift through solid and exceedingly hard rock. The distance was accomplished, working two machine drills side by side, and with an army of men working four-hour shifts, in less than 36 hours. Little hope was entertained from the first that any of the entombed men would be rescued alive, as it was apparent that the air-pipes must have been broken, but air was pumped into the pipes continuously, and the miners worked like demons, often refusing

to quit at the expiration of a shift. No cars were used, the muck being passed by shovel from one man to another, making a continuous line, and shooting was done every two hours. Men became sick from the powder smoke and were taken out and replaced by others, but there was not an instant's delay to let the smoke clear away, and every shot broke down at least 2 ft. of rock. When the cross-cut was finally reached, the body of Evan Reese, one of the miners, was found leaning against the sloping face of broken rock with his arms folded. The cave had left a space only about 10 ft. long, and in this he probably died from suffocation within 15 minutes. The other men, W. J. Bertsch and M. C. Matt, evidently tried to escape after hearing the first cave, and were caught beneath the falling upper ground, and were buried under thousands of tons of rocks. The search for their bodies is going forward night and day, but it may be weeks before they are found.

The Combination shaft and the northern portion of the Hampton stope are not affected by the cave, and the mine will now be opened from the fourth and fifth levels where it will be possible to extract a large tonnage of good ore more economically than before the ground fell. This territory will be opened by a system of 'glory-holing' to the surface, and nearly all of the caved material is of sufficient value to be put through the mill. Operations in the Combination mine will not be materially affected in any way by the mishap, but the company's production will be reduced for the time being by the amount treated heretofore by the Combination mill. There will be no curtailment of the tonnage handled by the 100-stamp mill as this can readily be taken from the Mohawk and Red Top mines.

Development from the Clermont shaft continues to produce the most gratifying results, and it is said on the highest authority that one of the best orebodies exposed on Consolidated territory is that which has been opened at the 860-ft. level where there is much high-grade ore in sight, and the ore-shoot is of large proportions. George Wingfield is here, having come from his home in Reno to attend the Mining Congress, but the caving of the Hampton stope has prevented his taking any active part in the work of the Congress. He has been at the mine with Mr. Mackenzie a large part of the time. The 600-ft. north drift from the Clermont has cut the hanging wall of the Red Top vein on the Lucky Boy claim, but the extent of the orebody at this point is still undetermined. At the 730-ft. level the ore has been followed for over 200 ft., and is from 12 to 25 ft. wide. The orebody lately opened in drifting from the 600-ft. level of the Mohawk is one of the richest exposed in the mine, and is in practically undeveloped territory with virgin ground all the way to the surface.

Reports from the Combination Fraction indicate that the orebody exposed a fortnight ago, and which has been opened at the 300 and 425 levels is maintaining its early promise, both in point of quality and volume. The seams of high-grade ore in which free gold is visible in abundance, and which appeared at first in the center of the vein, are now being found on the footwall as well, and it is said that the early averages of from \$120 to \$160 per ton across the entire breast of from 8 to 10 ft. are being maintained as the ore-shoot is further opened, and that the high quality of the ore has proved unexpectedly uniform. The output from the Fraction is about 80 tons daily, and the ore is graded for treatment to over \$40 per ton. The Fraction has a large tonnage of milling ore exposed at various levels, chiefly between the 250 and 450-ft. Another new vein of milling ore will add materially to the ore-reserves.

The Daisy mine is shipping two grades of ore, the first-class assaying from \$130 to \$160 per ton, and the second-class from \$25 to \$35. The mine has produced approximately \$250,000, and since the management has been in the hands of C. D. Wilkinson, now president of the company, barely one-tenth of the work has been devoted to production, the principal efforts having been confined to development. The mine has over two miles of underground workings and 50 men are employed on the ground. The deepest

shaft, 500 ft., is now being worked by two sets of lessees, and ore is being taken from the 200-ft. level and shipped to the sampler. The veins of the Daisy are of large size, averaging from 15 to 20 ft. wide, and the grade of ore is more or less irregular, though ore of excellent quality is found over a wide area. The equipment includes two electric hoists of 50 and 30 hp., a 100-hp. compressor, and an electric triplex pump which is installed at the 400-ft. level. Much of the Daisy ore is 'base,' and does not respond to treatment by the milling processes employed locally. With the completion of the Goldfield-Ely railroad, affording a short haul to the smelters of the latter camp, the Daisy will be enabled to market a large tonnage of ore which cannot be handled profitably under present conditions.

Three leases on the Daisy are in pay-ore. There are prospects that the financial difficulties involving the Diamondfield Black Butte Con. will be cleared up, and the company placed in a position to resume development. A plan of re-organization has been suggested by L. L. Patrick, president of the First National Bank of Goldfield and Frank M. Ish, president of the Black Butte, to whom the company is indebted in a sum approaching \$17,000. It is suggested that the property be sold to satisfy a judgment for the amount of the indebtedness, and that the two principal creditors accept the company's note for the amount, placing the note in the hands of a trustee or trust company by whom the re-organization shall be affected. Then it is planned to permit the exchange of the present stock for shares in the new corporation, share for share, upon the additional payment of 2 cents per share or, if the stock of the new company be made assessable, by the payment of $\frac{1}{2}$ cent per share. In the present company, which is capitalized for 2,000,000 shares, Mr. Patrick holds 120,000 shares, and Mr. Ish 300,000 shares. The smaller debts of the company have been paid during the past four months from royalties received from lessees and there is a small cash balance on hand, but not enough to begin mining operations. The mine, in which there are over 15,000 ft. of workings, has exposed large quantities of good milling ore, but a reduction plant will be required to make a profit from most of it.

Two deep shafts are being sunk on the Polverde claim, the joint property of the Consolidated and Jumbo Extension companies. Both shafts are to be sunk 1000 ft., and both will penetrate the Clermont vein in depth. All royalties from these operations will be divided equally between the two owning companies. The Grizzly Bear shaft on the Jumbo is close to the 800-ft. level, near which point it is expected to cut the Mohawk vein. Sinking will be resumed shortly from the 600-ft. level of the Nevada Gold Ore Mines Co.'s lease on the Gold Bar claim of the C.O.D. Consolidated, and the 500-ft. cross-cut from the latter company's Victor shaft has penetrated the vein, and a winze has been started in the ore. Thomas A. Lister is sinking on the C.O.D. claim at a point where high-grade ore has been found at the surface. The Pittsburgh Nevada Co., which recently acquired the Rialto group, giving it 91 acres about three miles east of the town, has cut through 35 ft. of vein at the 400-ft. level, the last 16 ft. being hard quartz, and the formation almost identical in character with that of the veins in the producing portion of the district. An 8-ft. vein was cut in the Rialto shaft yielding assays up to \$154 per ton. This shaft will be continued to a depth of 500 ft. Pay-ore is exposed at a depth of 600 ft. in the Stoneham-Moore-Griffiths lease on the Combination No. 2, near the bonanza Reilly lease, but a heavy flow of water has impeded progress of late. On the Red Hill but one lease is operating, that of the Mining & Ore Reduction Co., and this shaft will be sunk deeper. One drift on this ground has been driven 1800 ft. Local operators are working the Kendall shaft under lease, their territory embracing a portion of the Sandstorm. It is reliably reported that the orebody on the Goldfield Belmont is developing into one of great size, with assurance of a heavy production.

Railroad traffic has been so obstructed by washouts in every direction that the work of organizing the Mining Congress for effective discussion was considerably delayed.

GARDINER, MONTANA.

American Institute of Mining Engineers.—Tour of Yellowstone Park. —Transportation Difficulties.

The eastern members of the American Institute of Mining Engineers and their leaders who are journeying westward for the purpose of attending the sessions at Spokane, arrived at Mammoth Hot Springs, Yellowstone National Park, Saturday morning, September 18, a trip through the Park being one of the attractions incident to the meeting. From Chicago the party has been traveling in a special Pullman train, the cars being left at Gardiner, the gateway to the Park, where they will be held until this part of the trip is completed. The arrangements for the special train service had been made by Theodore Dwight, under whose charge similar parties of the Institute membership had been conducted on the trips to California, Mexico, Nova Scotia, British Columbia, and Alaska. Unfortunately Mr. Dwight's business engagements prevented him at the last moment from accompanying the party, but his place has been well filled by A. E. Vaughn who has been associated with Mr. Dwight on former trips, and who also managed the trip to Chattanooga last October. The service rendered by the Chicago, Milwaukee & St. Paul and the Northern Pacific railways in handling the train has been all that can be desired, the rather fast schedule arranged for having been exceeded in the accomplishment. This acted somewhat to the discomfort of one member who expected to join the party at St. Paul, and found that it had left an hour ahead of time. By a good sprint he caught up with the rest of the party at Mammoth Hot Springs Saturday morning. Saturday afternoon was spent in doing the usual tourist 'stunt' of going over the formation and enjoying the natural wonders of the Mammoth Hot Springs. Nearly everywhere one goes in the Yellowstone Park it is the formation that holds the attention.

On Sunday morning, almost in the cold gray dawn, well bundled up in sweaters and overcoats, the forty mile ride to Fountain Geyser and hotel was begun. Stop for lunch was made at Norris basin, and an hour or so was pleasantly occupied in going over the formation and receiving instructions from the guide in regard to the chemical and physical theories of geyser activity. More of formation was absorbed at the mammoth paint pots and the Taft geyser at Fountain, the geyser obligingly coming into play just at the brilliant sunset of what had been a cloudy gray day. In the evening after dinner, services were held in the large public hall of the hotel, Dr. Raymond addressing the company on the life and character of the apostle Paul.

Going through the Park is a strenuous occupation. Calls are made at 6 or 6.30 in the morning and no longer time than necessary is given for dressing and for breakfast, for the stages are at the door at 7.30 or 8 o'clock, and the starts are made promptly. There are consequently few temptations for late hours at night, and 10 o'clock sees the halls pretty well deserted. Monday morning was occupied in driving to Upper Basin where the star performer of the Park, Old Faithful, holds sway. Short stops at various formations along the route relieve the trip, but the performances of Old Faithful himself are the main attractions. The Institute party arrived at Old Faithful Inn at about 10.30 and although the day turned out to be one of wind and rain and snow, most of the travelers braved the elements and did the 'formation route' in regulation tourist fashion. "Day before yesterday" is, however, the proper time to visit this particular section of the Park, for then it is that the Grand, the Economy, and other spouters less regular than Old Faithful, have done their turns. Such at least was the experience of the Institute party. The illumination of Old Faithful by searchlight at night makes up for what one misses in other respects, however, and this effect at night, heightens the beauty of the eruption and is in itself worth the whole trip.

An early start was made on Tuesday morning for the ride across the mountains to Yellowstone lake, but the pleasure and comfort of the trip were marred by the cold weather and the snowshowers, and it was a chilled party

that arrived at the Lake Hotel that evening. A ride of eleven miles on Wednesday morning brought the party to the crowning glory of the Yellowstone, the falls and the Grand Canyon, and the afternoon was spent in the enjoyment of these wonders. The tour of the Park is well arranged to make these the last portion of the sight seeing, for it is bound to give even the most unappreciative visitor the feeling that he has had the worth of his money and has been repaid for the fatigues of his journey.

The opinion generally expressed was that in this day of electrical means of transportation, better methods for conveying tourists through the Park should be instituted. The old-fashioned stage is fatiguing and the travelers are rushed through the places of interest in a manner that detracts materially from the pleasure of a visit to this great public Park, dedicated to the "instruction and enjoyment of the people" but seemingly operated for the benefit of the Yellowstone Park Association. The roster of the Institute party as it toured the Park was as follows:

W. S. Ayres, Mrs. W. S. Ayres, Hazleton, Pa.; A. R. Bellinger, Syracuse, N. Y.; F. H. Bostwick, Mrs. W. H. Bostwick, Denver; D. Owen Brooke, Mrs. D. Owen Brooke, Birdsboro, Pa.; Dr. D. W. Brunton, Denver; Charles Catlett, Stanton, Va.; H. S. Chamberlain, Mrs. H. S. Chamberlain, Chattanooga, Tenn.; J. W. Dougherty, Steelton, Pa.; Miss J. L. Douglass, Brooklyn; Miss Anna Fries, Philadelphia, Pa.; Miss H. Gage, Denver, Colo.; Miss J. A. Glendinning, New York City; T. B. Greenfield, London, Eng.; Arthur Harrington, Miss Helen Harrington, M. H. Harrington, Mrs. M. H. Harrington, Philadelphia; E. S. Hutchinson, Mrs. E. S. Hutchinson, Newtown, Pa.; T. D. Jones, Scranton, Pa.; Reiji Kanda, Tokyo, Japan; Wm. Kelly, Mrs. Wm. Kelly, Vulcan, Mich.; Wm. Kent, Mrs. Wm. Kent, Sandusky, Ohio; A. H. Lawton, New York; John Lilly, Mrs. John Lilly, Wm. Lilly, Landisville, N. J.; Chas. McCrery, Birmingham, Ala.; W. S. Mitchell, Mrs. W. S. Mitchell, Haileybury; J. W. Nesmith, Mrs. J. W. Nesmith, Mrs. F. L. MacFarland, Denver; E. W. Parker, Washington, D. C.; J. G. Perry, Mrs. J. G. Perry, Denver, Colo.; Miss M. B. Pilling, Ross Pilling, W. S. Pilling, Mrs. W. S. Pilling, Philadelphia, Pa.; H. H. Pinkey, Thurmond, W. Va.; S. H. Pitkin, Cleveland, Ohio; Dr. R. W. Raymond, Miss Emily Saunders, Miss Jean Saunders, Miss Lopise Saunders, Mrs. W. B. Saunders, W. L. Saunders, W. L. Saunders Jr., New York; A. T. Shurick, Washoe, Mont.; Mrs. T. B. Smith, Norristown, Pa.; Dr. W. O. Snelling, Pittsburg, Pa.; Geo. Steiger, Washington, D. C.; Dr. Jos. Struthers, New York; A. E. Vaughan, Mrs. A. E. Vaughan, Brooklyn, N. Y.; S. T. Wellman, Cleveland, Ohio; C. R. Weiss, Philadelphia.

NEW YORK.

Nipissing Mines. — Dolores Dividends. — Camp Bird & Pachuca. — 'Porphyry' Coppers.—Guanajuato Consolidated.

At a meeting of the directors of the Nipissing Mines Co., held in New York this week, the regular quarterly dividend was increased from 3 to 5%. An extra dividend of 2½% was also declared. Up to the present time, Nipissing has been paying 3% per quarter regularly, and 2% extra. The Nipissing company reports \$8,000,000 as the value of the ore now blocked out. Veins 64, the Fourth of July, and the Meyer, are reported as showing \$3,000,000 in ore reserves, the Kendall and connecting veins, \$3,000,000, vein No. 122, which has been developed since June, \$1,000,000. The company has \$750,000 cash in the treasury, and \$500,000 worth of ore with the smelters. Upon the announcement of the increase in the dividend-rate, the stock sold up to \$13.50 per share, from which it has reacted about a point. The directors of the La Rose Cons. Mines Co. held a meeting at the same time. The La Rose dividend was not increased. The New York office of the Dolores Mines Co. reports a satisfactory condition at the mines at the present time. The condition, both as to ore reserves and earnings, is such that the directors have felt warranted in increasing the regular dividend from 12 to 18% yearly. It is reported that the next dividend will be on the basis of 24% annually. While on the subject of recent dividend declarations, it may be said that a prominent Camp Bird 'insider' states that Camp

Bird, Ltd., will at the next meeting of the board of directors, increase the regular dividend from 20 to 40% yearly. The same person states that the Camp Bird-Santa Gertrúdis deal will be closed within the next 30 days. A substantial deposit has already been made at the City of Mexico to bind the bargain, and it is regarded here as definitely settled that the ownership of this famous Pachuca property will finally land with the Camp Bird company.

The sensation of the week in mining circles is the hot fight being made by Newman Erb to wrest the control of the Davis-Daly from F. A. Heinze. Both sides have sent appeals to shareholders for proxies for the annual meeting which is to be held next Monday. Erb is making his campaign for control on the plea that the Heinze management has been extravagant, and that the situation requires conservative handling.

The announcement is made in New York that James W. Malcolmson has been appointed consulting engineer for the Lucky Tiger Combination Co. The Lucky Tiger is the mine recently examined by Thomas H. Leggett and F. Hellman, under an option at \$6,250,000. The option was allowed to lapse. It is reported here that other interests are negotiating for the property.

The chief interest in the New York mining markets continues to be in the so-called 'porphyry' coppers. The only one of these stocks which has shown any weakness of late has been Ely Central. It is reported that the Calumet claim of this company is not developing as well as had been anticipated, although the Globe claims have been developing exceptionally well. The weakness in this stock is partly to be explained by the above reason, but it is also partly due to one of the largest shareholders selling out for the purpose of obtaining funds to start a market campaign on another 'porphyry' copper property upon which W. A. Farish has just returned a rosy report. The rumor that the Cole-Ryan interests are to consolidate the properties in which they are interested at Ely, is gaining currency, and it is believed that an announcement covering the matter will soon be made. The Cole-Ryan people, besides owning control of the Giroux, have, as is well known, recently obtained control of the Butte & Ely, and a number of other properties in the Ely camp. It is stated that a consolidation will be effected on a financial plan similar to that employed by the Nevada Consolidated Copper Co. some time ago.

At the office of the Exploration Company of New York, the announcement is made that the earnings of the Guanajuato Consolidated Co. for August were \$47,700, as against only \$6000 in February. The installation of filter-presses and other modern metallurgical devices, and a slight increase in the grade of the ore, have accounted for a regular monthly advance in the output of this mine.

Thomas W. Lawson has started a new campaign, having for its purpose the bulling of copper stocks. As a result of his campaign, this time not by advertising but by circularization, there is increasing activity in Chino and First National, and a broadening market. These are the two stocks which Lawson is particularly booming.

MEXICO.

Petroleum Refinery.—Cia. Minera de Naica. — Seguranza, Zacualpan.—Santa Gertrudis Negotiation.

The petroleum refinery of S. S. Pearson and Sons' is situated at Minatitlán on the Coatzacoalcos river, about 40 kilometers above the town of Coatzacoalcos. The capacity is about 5000 bbl. per day, and about 200 bbl. of asphalt. A plant is also being erected for manufacturing lubricating oils. The oil fields from which the crude oil is obtained are about 25 kilometers further up the river at San Cristóbal. There is another field at Concepción. The oil is obtained at an average depth of 800 ft.; there are no gushers, all are pumping wells. The Mexican Fuel Co. struck oil recently in a well on the Santa Fe ranch on the Panuco river, about 45 miles from Tampico, and 25 miles southeast from the Ebano oil fields. The well was drilled in four months, and oil was struck at a depth of 2455 ft. The well was drilled without casing, and oil was found in the hard rock at the

depth indicated.

It is stated that the large percentage of salt water pumped up with the oil from the Ebano oil fields was the cause of the shortage in the supply of fuel oil, for the locomotives on the National railroads. Experiments are being made for the mechanical extraction of the water from the crude oil. The contract with the railroad specified that there shall not be more than 5% of water with the oil, and recently the amount of water in some cases was as high as 20%.

The silver-lead mines of San Pedro, at Naica, State of Chihuahua, owned by the Cia. Minera de Naica, have been splendid dividend payers in the last two years. From the start, the gross output of ore has amounted to \$5,449,568, out of which \$2,650,800 has been paid in dividends. The property consists of 48 pertenencias, or mining claims, and a narrow gauge private railroad from the mines to Conchos station on the National railroad, about 80 miles south of Chihuahua. This narrow gauge has a length of about 27 miles. The high-grade ores so far shipped average about 400 grams silver, and 3 grams gold per ton, with 22% lead, 20 iron, and 10 lime. The company has decided to erect a 600-ton smelter at Conchos, which it is estimated will cost a million pesos. The plans for the plant are now being prepared, and while it will be designed with special reference to the ores from this mine, it will also be a custom smelter.

G. A. Waddell, acting for the Seguranza company, has recently purchased the Ampliación Norte de Olvidado, near Zacualpán. This mine has 21 pertenencias, and adjoins the Seguranza on the north, being between the famous Carboncillo and Coronas mines. The group of mines now owned by the Seguranza company are of such importance that this concern ranks as one of the most important in the district. J. W. Nibel is general manager of the company's mines at Zacualpán.

The sale of the Santa Gertrúdis property, which was reported as practically settled, has been again postponed as the result of an extraordinary meeting of the stockholders held at Pachuca on September 13. After much discussion the meeting was adjourned for 15 days so as to consider the rights of the majority stockholders, and also to give time for a commission to report on the actual conditions of the property. The commission appointed consisted of consulting engineer Edmundo Girault, Julio Limantour, and an attorney named Elguero. It is interesting to note that a short time ago Girault claimed that the mines were worth a great deal more than \$9,000,000, whereas the report made to the board by José Calero, shows a total value, including ore blocked, and probable ore, of \$10,210,840.

The Monterey-Tampico branch of the National Railways which was washed out by the recent floods will not be open for traffic for six weeks.

BUTTE, MONTANA.

September Copper Output.—Parrot Development.—Minnie Healy.—North Butte Troubles.—Murray-Switzer Case.

During 28 working days in September the Butte mines yielded 380,240 tons of ore, producing 26,584,180 lb. of copper, an increase of about half a million pounds over August. The companies are represented in the totals, showing daily averages of ore and copper production, and average yield of copper per ton of ore, as follows:

| Companies. | Daily Tons. | Lb. per Ton. | Daily lb. Copper. |
|--------------------------|-------------|--------------|-------------------|
| Boston & Montana | 3600 | 76 | 273,600 |
| Anaconda | 3600 | 62 | 223,200 |
| Butte & Boston | 650 | 63 | 40,950 |
| Washoe | 550 | 62 | 34,100 |
| Parrot | 400 | 58 | 23,200 |
| Trenton | 405 | 61 | 24,705 |
| North Butte | 1395 | 84 | 117,180 |

The Parrot company is still finding the richest ore of the

Parrot mine on some of the intermediate levels, especially on the 1600 and 1800-ft. The two new levels at the 1900 and 2000-ft. are not showing up well, but during the past month a new and splendid orebody has been opened on the 1800-ft. from which 'glance' ore is being mined. The Parrot vein has always been erratic in size and richness. On the new levels the vein has maintained a good size, but the ore is low-grade. The Parrot is not yet at the depth at which the Anaconda company, in the adjoining ground, found its richest ore.

The recent find in the Minnie Healey mine at a depth of 1700 ft. by the Butte Coalition company continues to improve with development. Four veins have been cut by the cross-cut from the 1700-ft. station of the Tramway shaft, two of the veins being new and not known to exist above the 1400-ft. level, where the apex was cut. The second of these veins, less than 170 ft. from the shaft, may be a branch of the Minnie Healey, but that has not yet been determined. It has a width of 6 to 12 ft., though it narrows at places to a foot. Driving is being done, and the ore in the entire width is said to average 36% copper, and much of it as high as 54 and 60. The main Minnie Healey vein, is also being driven on, though the vein has not yet been traversed. Ore in the face of the drift assays higher than 6% copper, though it is not expected that the entire vein will be found to contain such a high average.

James A. Murray, a millionaire banker, who has brought suit against the Anaconda company over the apex of a portion of the Bell-Speculator, or Edith May vein, is now engaged in a litigation by which he hopes to get control of the Butte Monitor Tunnel Mining Co. for \$20,000. A great deal of the stock of the company is owned by Easterners, but the majority of the 3,330,000 shares is, or was, owned by William S. Switzer, the original owner of the property, a feeble old hermit, about 85 years of age. Recently 1,500,000 shares of the stock owned by the old man was in danger of being sold by the sheriff to satisfy a judgment for \$17,500, and a money broker advised him to borrow sufficient money from Murray to pay off the judgment. He got \$20,000, and paid \$2500 of it for commissions, agreeing also, so he says, to pay a reasonable interest. He discovered that he agreed to pay \$10,000 for the use of the \$20,000 for four months, and now Murray is suing to enforce the transfer of about 2,200,000 shares which Switzer thought he had put up as collateral security. Murray claims that he bought the stock outright for \$20,000, and merely gave Switzer an option to repurchase his own stock for \$30,000. Switzer has repeatedly refused offers of \$75,000 to \$500,000 for his controlling interest in the company, but he is now in danger of losing it all for the \$17,500 judgment which Murray paid off for him. The company owns seven claims on the east side of the Butte district. A tunnel 1600 ft. long has been driven on one claim, cutting seven veins, giving at a depth of 200 to 300 ft., some fair copper and silver assays. Much of the stock of the company is owned in Ohio and New York, and the stockholders will probably be interested in the news that Murray may get control of the company.

The Eastern stockholders of the North Butte Extension Development Co. are still holding meetings and conducting investigations. A few weeks ago a committee of stockholders made a report but no serious recommendations or findings were made, so far as the Butte stockholders have heard. Notice was given later of another 'informal' meeting to be held in New York September 30 'for the purpose of inquiring into the affairs of the company'. This was sent out by Joseph O. Morris and E. S. Thatcher. It announced that F. O. Weeks, of New York, Dudley A. Tynge and A. M. Andrews, of Chicago, would be invited to be present.

The company has lost its options on the fractional interests in the Occidental, Free Trade, and Overman claims, but it owns some undivided interests in those properties, and owns outright two mill-sites and a small fractional lode-claim on which the company's shaft is situated. It is probable that the company can obtain a renewal of the expired options, if it ever gets into financial condition to indicate its ability to do business. It has no indebtedness, and a large majority of its stock remains in the treasury, but among all the new companies organized in the Butte

district none has been so unfortunately managed as the North Butte Extension. Its property is favorably situated, and the belief is general that had the company been given a fair chance by its officers it would have developed into a producing mine.

TORONTO, CANADA.

Provincial Mine Sold — Waldman Mine. — Colonial Mill. — Cobalt Output. — Buffalo Cyanide Plant at Cobalt.

The sale by the Ontario Government of the Provincial mine on the Gillies timber-limit has been effected, the price received being \$113,111. The purchaser was F. M. Connell, of Halleyburg, whose tender was the highest received. The mine was sold subject to a 10% royalty on the gross output. There is a good plant, including a 100-hp. boiler and an air-compressor with pumps, and two shafts down 140 and 70 ft. respectively, from the younger of which considerable driving and cross-cutting has been done. Fifteen other properties on the limit, also subject to 10% royalties, were likewise sold, which comprised a total acreage of 319 acres, realizing \$109,943. The highest price received for any lot was \$20,600, and the lowest \$2250. The recent discoveries on the Waldman property had a marked influence in stimulating competition, the bids being considerably higher than those received at the previous sale. So ends the Ontario Government's policy of operating mines, which will be a sore disappointment to the advocates of public ownership, who regarded Premier Whitney as a staunch upholder of their principles. It is understood that one of the main reasons which induced the Government to get rid of the Provincial mine was that the officials of the Department of Mines might be free to undertake a thorough exploration of the Gillies Limit, only the fringe of which has yet been gone over. As it comprises in all 64,000 acres, much of it still thickly wooded, this will be a difficult and tedious task.

The principal interest as regards Cobalt now centres around the Waldman silver mines. The organization of a company has been completed, and development, which is being vigorously pushed, has fully confirmed the promise of the surface explorations. The shaft is down 42 ft. in good ore. An assay of ore from the 30-ft. level showed 10,668 oz. silver per ton. Fifty men are engaged in surface trenching. Ore is being taken out at the rate of about 40 bags per day. At the Temiskaming the shaft is being put down from the 300 to the 350-ft. level.

After having installed a test leaching plant, which proved unsuccessful because of its small capacity and mechanical inefficiency, T. R. Jones, superintendent of the Buffalo property, at Cobalt, still maintained that cyaniding was essential to the most efficient treatment of the ore. After three months of testing it was decided to erect a slime-plant, and further experimenting was carried on. The cyanide plant, which is now in operation at the Buffalo has a capacity of 50 tons of dry slime per 24 hr. In the concentrating plant the ore is crushed and jigged and then classified for concentration in a drag classifier, designed by Groch Bros. The sand is concentrated on Wilfley, James, and Deister sand-tables, and all of the slime, including that formerly treated on the Deister slime-tables, is sent to the top of the cyanide plant, by a Morris centrifugal pump, where it is sampled by an automatic clock sampler, and passed through a screen into the collecting vats. The thickened pulp is drawn from the bottom of the collecting vat through a 6-in. pipe, and is deposited by gravity into the dewatering tank, which is fitted with vacuum filters. The cakes are dropped off of the filters and agitated by air with the solution and are then pumped back to the treatment-vats when it undergoes an agitation of 48 hr. This is done by means of mechanical and air-agitation combined. The filtering plant is of the vacuum type, with stationary, vertical filters of the style originally designed by F. G. Underwood in the Black Hills. The clear silver-bearing solutions through the vacuum pumps are pumped from the filter-tanks to the pregnant-solution tanks, from which they are drawn off to the zinc-boxes for precipitation. By means of zinc shavings in upward flow zinc-boxes, 95% of the silver is deposited, the remaining 5% being carried continuously in the

solutions. The recovery from the ore is 85%. The successful cyanidation of Cobalt ores opens up a new era for the camp, as lower grade ore can be treated. Frank Groch has been in charge of the operations and N. C. Groch has been assisting in the erection and installation.

GUADALAJARA, MEXICO.

Guanajuatillo Mine, Tepic.—*San Fernando, Durango.*—*Smelter at Choix.*—*Mina Grande, Hostotipaquillo.*—*Chapala Hydro-Electric and Irrigation Co.*—*Oro Grande Flotation, Guanajuato.*

The old Guanajuatillo mine, in the Territory of Tepic, has been partly unwatered by the Castellana Consolidated Mines, Ltd., of London, and good ore has been found in the old workings that can now be entered. The Guanajuatillo was at one time a rich producer, and according to its history high-grade ore was being secured when the workings were flooded and the miners driven out. The company has gone to considerable expense for unwatering the property, having installed a hydro-electric plant and electric pumps, but it expects to be rewarded when the deepest workings are emptied. The Castellana Consolidated was organized eight years ago to take over and work the old Castellana mines in Tepic, and it has been very successful in its operations. However, the Castellana mines are regarded as practically worked out, and attention is being centered on the Guanajuatillo. A reduction plant at La Playa, on the Santiago river, is also the property of the company. The Casados Mining Co. has secured control of the old Amajac reduction plant in the Hostotipaquillo district of Jalisco, and will use it for experimental purposes, preparatory to the erection of a 100-ton plant of modern construction at the Casados mines in that district. The Amajac plant has been owned by Carlos Romero, and has been doing considerable custom work. Stockholders of the Copper Range Mining Co., of Chicago, owning copper properties in the Autlán district of Jalisco, have brought legal action to secure an accounting from C. D. DuBois, the president and general manager. They charge that he has been neglecting the interests of the company. The company was organized a few years ago to acquire the Autlán properties, but little work was done up to last year, when development was resumed under the direction of Mr. DuBois. Soon after the organization of the company equipment for a 50-ton smelter was purchased and shipped to Guaymas, where it remained until early this year, when it was moved to the Jalisco port of Chamela and unloaded. A wagon-road from Chamela to the mines has been under construction. A. H. Harrison, an English mining man who recently secured an option to purchase the old Refugio mine in the Hostotipaquillo district of Jalisco for \$80,000, has allowed the option to expire. He took the contract to England, but failed to make a deal. Mr. Harrison owns the La Luz copper mines in the Ayutla district of Jalisco.

A report that a big body of ore averaging 1 oz. gold and 15 oz. silver per ton has been opened in a new working on the vein of the old San Fernando mines in the Topia district of Durango, not a great distance from the Sinaloa boundary, recalls the fact that the Fernando Mining Co., of Boston, after purchasing them for \$250,000 and spending several hundred thousand dollars in development work and equipment, made a present of these properties to John T. Canfield, of Culiacán, Sinaloa. Mr. Canfield has sold an interest in the mines to H. G. Zeigler, and a reduction plant it now planned. Mr. Canfield, a well known American business man of Culiacán, was authorized to sell the mining, hydro-electric, and reduction machinery that had been installed, and later the titles to the mines were turned over to him as a gift. New development has been in progress for some time, and according to late reports there is now promise that the mines will become big producers. It is expected that work will be resumed on the Kansas City, Mexico & Orient railway in Sinaloa soon after the close of the present rainy season. The line has been completed for a distance of 80 miles east of the port of Topolobampo. The Choix Consolidated Mining Co., of Los Angeles, plans to build a 100-ton smelter near the point where the railroad will cross the Fuerte river, about 125 miles from Topolo-

bampo. It will be a custom plant. A body of 8% copper ore, with a good silver content, has been opened in the Plátanos property of the Plátanos Development Co. in the Choix district of Sinaloa. The Plátanos ores will be treated at the Choix Consolidated smelter.

Francisco J. Fournier, the Frenchman who developed the great Dos Estrellas mine in the Talpujahua district of Michoacán, is one of the men behind the plans for the extensive development of the old Mina Grande in the Hostotipaquillo district of Jalisco. He has taken a big block of the stock of a company recently organized with a capital of \$300,000. The Mina Grande was recently purchased from the Dwight Furness Co., of Guanajuato for \$75,000, and since that time several adjoining claims have been bought from Frank G. Stevens and others for \$20,000. Mr. Fournier is the principal stockholder in the Dos Estrellas Mining Co., and his Dos Estrellas dividends have made him a millionaire. The Chapala Hydro-Electric & Irrigation Co. has secured a loan of \$2,200,000 from the Caja de Préstamos, of Mexico City, and part of the money will be spent on the transmission line from Guadalajara to the Etzatlán and Hostotipaquillo mining districts. The iron towers for the cables are being erected, and power is now promised Etzatlán concerns by January 1, 1910, and those of the Hostotipaquillo district by the following March. H. E. Crawford, representing the Marcus Daly estate, is shipping some high-grade ore from the Cinco Minas in the Hostotipaquillo district. The \$200,000 worth of development machinery recently ordered by Mr. Crawford has been unloaded at the present Southern Pacific terminus beyond Tequila, and some of it is on the way to the mines. Arrangements have been made for its immediate installation. A. J. Vick, of San Antonio, Texas, who last year purchased the old Deseada, Espada, and San José mines in the Hostotipaquillo district for \$150,000, has bought the Esperanza and San Pablo, extensions of the San José, from Alfred Lundvall for \$50,000. A reduction plant with an initial capacity of at least 100 tons per day will be built. The Peñoles Mining Co., owning the custom smelter at Mapimí, Durango, has purchased the Resolana, La Perla, and Dewey mines in the Parral district of Chihuahua, and shipments from the properties to the Mapimí plant will soon be in progress. The mines will give the Peñoles company a steady supply of silicious ores. The Llanitos Consolidated Mines Co. of St. Louis, Missouri, now in control of the Llanitos group of mines at La Portilla, Durango, is installing a hydro-electric plant to furnish power for electric drills and other mining machinery. A 50-ton stamp-mill and cyanide plant will be built next year. Plans for extensive development have been made.

The Cubo Mining & Milling Co., of Chicago, operating the Cubo group in the Guanajuato district of Guanajuato, has completed La Loca tunnel to the old Villapando mine, and that property will now be cleaned out and further developed. The tunnel was started many years ago by an English concern, and is one of the longest in the Guanajuato district. The present Cubo reduction works, consisting of 20 stamps, Huntington mill, concentrators, and cyanide annex, is soon to be replaced by a big plant of the most improved construction. E. N. Funston is now in charge of operations for the company. It is stated that the Securities Corporation, Ltd., which is handling the Oro Grande flotation, is meeting with success, and that money for the proposed operations in the old La Luz camp of Guanajuato will soon be available. The Oro Grande Mines Co. was recently organized to take over and re-open the old La Luz, Refugio, Bolañitos, Melladito, and Tolentino mines and build a reduction plant of 1000 tons capacity. In the event the flotation is a success it is probable that the Mexican Milling & Transportation Co. will build a railroad to give La Luz connection with the National Railways. This latter company was organized a few years ago to operate milling plants and build a belt-line to connect the principal mines and mills of the Guanajuato district with the Mexican Central, now a part of the merger system (National Railways). However, there is no doubt of the belt-line plans being carried out. A rich find was recently made in the Tajo de Dolores mine, which is controlled by the Proprietary Mines Co. Some of the ore assayed as high as 55 kilos silver and 240 grams gold.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Dredging on the Fraser River.

The Editor:

Sir—The fact that dredge mining on the Fraser river, British Columbia, has so far failed despite the enormous harvest of gold its bars yielded in the early history of the province has been a cause of wonder to mining men. At the present time the Fraser river is condemned as a dredging field by the majority of mining men who have examined it, for what might seem the good and sufficient reason that during the last 10 years several companies have operated and gone out of business. The Fraser river, in spite of all this, affords as good opportunities for dredging as many districts where the industry is on a sound, paying basis. I have been actively connected with the dredging industry on the Fraser river for over six years, and I have had several years' experience in New Zealand and California, so I feel that I can speak with some authority on the subject. Before dealing with the causes of the failure of dredging in this district, a few words on the auriferous deposits of the Fraser river will be necessary. Starting at Hope on the Fraser river, 88 miles from Vancouver, and extending to the town of Lillovet, a distance roughly of 120 miles, one finds at frequent intervals large gravel bars, some of them over 100 acres in extent. These bars in most cases show at low-tide, but during high-water, in the months of June, July, and August, are partly submerged. It was from the surface of these bars that the large amount of gold produced on the Fraser river during the last 50 years has come. Dredging on these bars at different points has shown the value to be from 10 to 25c. per cubic yard. The total available area for dredging should be close to 3000 acres.

To turn to the causes of failures: At Lytton the first so-called modern dredge on the Fraser river was built by the Cobeldick Dredging Co. in 1900. This company, disregarding the large gravel-bars lying above low-water mark built a dredge that could work only in the bed of the river. The best returns were obtained along the edges of the bars, and the operation with this boat proved that the gold was concentrated on the bars. Although in many respects this boat was capable of excellent service, in other ways it proved unsuitable; the gold-saving tables were inadequate, not having area enough for the scaly nature of the gold. Although alterations could have been made at a slight expense, the directors of the company decided to discard the dredge and build a new one. This dredge was supplied by an English company with very little experience in the business, and proved a total failure. The machinery was too light, no allowance being made for wear at all; the length of ladder only allowed it to dredge to a depth of 25 ft., so that a rise of a few feet in the river put it out of commission entirely. Furthermore, the dredge had so little freeboard that it was almost im-

possible to move it in the current. Only after weeks of delay, strengthening different parts, and altering others, was the dredge got to work; then all it was fit for was prospecting. Several bars were prospected with it, and the results were so encouraging that the directors made repeated efforts to raise capital to build another dredge, but the stockholders cried 'enough'.

The next company to operate on the Fraser river was at Lillovet. Unlike the Cobeldick company at Lytton, this company made provision to work the bars on their property, that they had prospected beforehand with highly satisfactory results. This dredge has been at work several years with varying success. The first season's run proved profitable, but litigation among the stockholders tied up the dredge for a lengthy period. This property has recently fallen into the hands of a Boston company which operated it for a season. This dredge is at present leased to a party of experienced dredge-men, who are working with satisfactory results.

In 1906 a third company was organized by one of the most successful dredge owners in New Zealand to work a 15-mile tract leased on the Fraser river at Yale. This company repeated the mistake of putting on a dredge without a stacker, and in not acquiring the right to dredge the bars. The unprecedented cold weather of that winter caused the dredge to be frozen in for some months, so eventually they were glad to sell to a company owning an adjoining bar-lease. The company acquiring this dredge operated for some months at a profit, but during a heavy freshet in the river the dredge was wrecked beyond all hope of salvage. I believe that the Fraser river offers today splendid opportunities to those looking for dredging property. The greater part of the area can be prospected with the Keystone drill.

Mention is often made of the difficulties met with in dredging on the Fraser river, and no article would be completed that did not refer to these. Most of these difficulties are found in the attempt to dredge the deep channels. In many places the bed of the river seems to be literally paved with rocks. While they can be handled by the dredge-buckets, yet they entail heavy wear and tear on the dump-chutes and grizzlies. In the bars, however, this feature is absent. Then the 'mush' ice running in the river in winter causes delay by choking the pumps and pipes. A dredge working in the bars, and away from the current, avoids this, and the same applies to the swift current at high-water. Another point is that the gold being of a scaly character requires a larger spread of tables to treat the material lifted, and a separate engine for the pump must be employed, so that the supply of water to the gold-saving tables can be regulated according to the character and amount of material being lifted. This was not done in two of the dredges referred to in this letter, and was a bad feature of their design. The working season should average 10 months. During the last 10 years there have been some when a dredge would only have lost a few days on account of cold weather. On the other hand, however, an exceptionally long cold winter might tie a boat up for three months.

Pierce, Idaho, August 10.

JOHN WATT.

MODERN PROGRESS IN MINING AND METALLURGY IN THE WESTERN UNITED STATES.

By DAVID W. BRUNTON.

*The more recent and important improvements in our Western mining practice which have contributed most toward the advancement of the art may be briefly summarized as follows.

Mine-Mapping.—Not many years ago most mining companies thought it amply sufficient to have a surface map of their properties and a composite map showing the different underground workings in their mines. Today, almost every important concern maintains, in addition to the above, both stope and assay-maps, while many of the larger companies add individual-level horizontal and vertical cross-section maps showing the underground geology in full. Upon these maps conventional designs in black ink are used to designate the various rocks, while the different veins or vein-systems are shown in colors. These sections are frequently drawn also upon glass sheets, which are then inserted in wooden frames provided with vertical or horizontal slots or grooves cut at the proper relative distances apart to correspond with any desired planes of cross-section or with the working levels of the mines in question. The great advantages of such plans and sections cannot be overestimated. They not only show at a glance the tonnage and value of the ore in sight, but also afford a guide for development, whereas the old-fashioned maps were nothing but a record of the work performed, and were practically useless for any other purpose. The improvement has led to another advantage the importance of which is just beginning to be recognized. I refer to the employment by large mining companies of economic geologists, who are not burdened with the duties of surveying, directing workmen, etc., but give their whole attention to the geological problems found in the work. The advice of such experts in the purchase of property, the running of exploration-drifts, the location of shafts, etc., and the interpretation of local fault-systems, and other structural features, has already proved of inestimable value to their employers.

Surface Mining.—Large orebodies occurring near the surface can, in many cases, be most cheaply and satisfactorily mined by stripping off the overburden and loading the mineral into cars by either the 'milling' or the steam-shovel system. In the West, steam-shovel mining is confined almost entirely to the low-grade copper deposits at Ely, Nevada, and Bingham, Utah. The system employed follows closely that of many iron mines of Minnesota; and 95-ton shovels, with 3.5 cu. yd. (7-ton) dippers, are in common use. At Bingham, the Boston Consolidated Co. stripped the overburden from its deposit at the rate of 200,000 tons per month. The maximum amount handled in a calendar month was 282,903 tons, in August 1907, and the maximum output for a single day, with four shovels, is 15,000 tons. The Utah Copper Co., immediately adjoining this, is also carrying on equally extensive stripping and mining; and as many as 13

steam-shovels and 26 locomotives have been counted at work within a radius of half a mile.

Rock-Drills.—The great improvements in core-drills, both diamond and calyx, enable us today to explore ground hundreds of feet in advance of the actual openings, and afford great aid in all development. Power-drilling has now almost entirely replaced hand work, and a vast assortment of drills has been placed on the market, from which a careful engineer will often have extreme difficulty in selecting the machine best adapted for a particular service. Rock drills, reciprocating, air-hammer, and electric-air, are all in successful operation today; and with the steady improvement, both in design and material employed in construction, there is every reason to believe that the drill of the near future will be even more nearly perfect than those now in use.

Hoisting.—Thirty years ago, while immense hoisting plants were in use on the Comstock, they were far from efficient, and were not copied even in miniature on smaller mines. The favorite plant in Colorado in the early days was called the Gilpin county hoist, and consisted of a drum securely fastened at one end to a large wooden pulley connected by a slack belt to a stationary engine running continuously at a slow speed. When the signal was given to hoist, the operator opened the throttle of the single-cylinder engine and brought the necessary working tension on the belt by means of a tightener operated by a hand-lever. Today these primitive machines, large and small, have all been succeeded by direct or gear-connected steam engines, equipped, whenever the tonnage is sufficient to justify the expense, with variable cut-off valve-gear, post-brakes, and every modern improvement. Steam-hoists, capable of handling from 10 to 20 tons of total load, from depths of from 4000 to 6000 ft., at speeds varying from 4000 to 5000 ft. per minute, are now not at all uncommon. These immense plants are fitted with every imaginable device for increasing the efficiency, rapidity, and safety of operation, and the skill and artistic ability displayed in the design of some of the later Nordberg creations bring them to a point where they can almost be considered works of art. In many places where water fit for use in boilers is scarce and electric current cheap, as at Cripple Creek, the electric hoist has almost completely replaced the steam-hoist. When large electric hoisting plants were first installed it was found that the great amount of current necessary to start and accelerate the load brought a very objectionable 'peak' on the transmission line. This difficulty has now been overcome by the Illgner and other similar systems, in which the energy stored in a large rapidly revolving fly wheel cuts down, if it does not entirely prevent, the objectionable peak. Safety devices likewise have been very much improved; and a recent invention, whereby the cage tender is in constant connection with the engineer, should do much to decrease the number of shaft accidents.

Underground Tramming.—When mines were shallow, shafts numerous, and hoisting facilities inadequate, hand tramming was almost universally employed, but with increase in depth came the necessity for better hoisting machinery and a reduction in the

*Presidential address before the Spokane meeting, September 1909, Amer. Inst. Mining Engineers.

number of shafts, thereby increasing the distance over which ore had to be trammed. Then it was found that a high priced man constituted a very expensive motive power for pushing cars; horses and mules were put into commission; and, still later, air and electric locomotives have come into very general use. There has been much discussion concerning the relative merits of the two latter systems of underground haulage; but there is no doubt that each has its own field. Where the openings are dry and the roof sufficiently high and firm to carry the trolley-wire insulators, there is not question as to the desirability of using electricity, but where these conditions unfortunately do not obtain, the compressed-air locomotive is an excellent substitute.

Timbering.—Where the orebodies do not exceed 10 or 12 ft. in thickness, and have a firm hanging wall, nothing can exceed the cheapness and simplicity of stulls; but when larger orebodies are opened and timbering is necessary, the system employed is that of square setting, invented by Deidesheimer and first used at the Ophir mine on the Comstock lode in 1861. Timber is yearly becoming more expensive, does not usually last well underground, and when the orebodies are large, especially if there is a tendency to movement in the walls, square sets made from square timbers are apt to 'swing' and afford little vertical support. When large quantities of timber are required for square setting, in situations where the distance from the forest to the mine is not too great, round timbers are much cheaper and more durable than square. A round log has about double the strength of a square timber cut from the inscribed square on its small end; and since, in the round log, the concentric rings of growth are unbroken and each protects the ring immediately underneath it from decay, the comparison, both in cost and in durability, is very unfavorable to square timbers. Automatic framing machines can now be had which utilize the full strength of round timbers by making a bevel-joint outside of the square tenon necessary in all square set timbering. This additional segmental contact-area in the joints braces the round timbers so that they are much less liable to 'swing' in large stopes than the square.

In some cases 'cut and slice' and 'caving' methods are employed, in which the hanging wall is allowed to come down and rest on each successive floor as the ore is stoped out, and is prevented from mixing with the ore by a mass of crushed timbers and plank which follows down on the top of the receding ore. In the Utah Copper and Boston Consolidated mines, at Bingham, Utah, about 4000 tons of copper ore are mined per day by the 'caving' system. In some large mines the stopes are filled with waste as fast as they are freed from ore, and the ground above thereby prevented from caving, in the same way as if stulls or square setting were used. Steel and concrete are coming slowly into use in shafts, stations, and tunnels, and with the natural decrease in the price of iron and cement on the one hand and the rising cost of timber on the other, it is easy to see that the more durable forms of construction will eventually supersede wood on all permanent work.

The direct-replacement system employed in the

Rio Tinto copper mines in Spain succeeded perfectly in holding both walls and surface in place on a vein from 200 to 260 ft. wide, and, by taking advantage of the wonderful skill of the Spanish miners in building dry stone walls, gives a new method of safely and economically mining the lower portions of the lodes which cannot be reached by the open-cast systems extensively in vogue there.

Pumping.—In the United States during recent years the direct-connected steam pump has been developed into a most efficient pumping machine with duplex, triple expansion engines and every refinement possible in modern steam engine practice. These have in many places been superseded by the electric-driven plunger-pump, in which the high speed of the electric motor has been reduced by suitable gears. Later, quite a large number of electric pumps have been built in which the gear is entirely eliminated. The speed of the motor has been reduced, and that of the plunger raised, forming a combination known as the express pump. Pumps of this class, with capacities of 1600 gal. per minute, raising water 1550 ft., are now being successfully employed in unwatering the Comstock Lode at Virginia City. Within the last few years great improvements have been made in the electric-driven turbine pump which, with its entire absence of valves and reciprocating parts, promises to become a dominant factor in high-lift pumping. Already we have single-stage turbine pumps raising 35,000 gal. of water per minute 150 ft. high; five-stage pumps raising 10,000 gal. per minute 600 ft.; six-stage pumps raising against 800 ft. head; and eight-stage pumps raising 400 gal. 1400 ft.; and responsible firms are ready to contract to raise water by this system to any elevation up to 2000 ft., and guarantee a pump efficiency of from 60 to 75%, according to conditions of service.

Lighting and Signaling.—Incandescent electric lighting has long since driven oil lamps and candles out of the underground stations and permanent levels in which any large amount of work is carried on. The recently invented tungsten lamp with its high efficiency, giving 20 c.p. with an expenditure of only 25 watts per hour, makes it economically possible to extend electric lighting very greatly throughout underground workings. In some of the largest and most progressive mines, candles and oil lamps have already been replaced in the stopes by acetylene, which is not only cleaner and safer, but gives a much greater illumination for a given cost. For mine signaling, the flash-light system operated by interrupting, by means of well protected switches, the current passing through the station lamps, is rapidly replacing the old fashioned cumbersome bell cord; and the latest moisture proof mine telephone gives instant communication throughout the underground workings, and to and from the surface, with little danger of interruption.

Explosives.—The use of modern high explosives in mining and tunneling is now universal; but there is a crying demand for an explosive which can be more safely handled, and which on explosion or detonation will produce a smaller amount of noxious gases, which not only injure the health of the miners, but delay the resumption of work after each round of

shots has been fired. Irregularities in the composition of explosives, variations in the strength of detonators, and differences in the speed of fuses are all fruitful sources of mine accidents; and, while too much 'paternalism' is certainly to be avoided, it is doubtful if anything short of Government regulation and inspection of explosives, detonators, and fuses will ever bring about the uniformity necessary to safety.

Ventilation.—Less progress has taken place in this department than in almost any other, although the means for moving large quantities of air under slight pressures have been very much improved. The ventilation and cooling of metal mines have not yet received the attention which their importance demands. In this respect Western engineers could take profitable object lessons from their brethren in the coal-fields. Very few of our Western mine operators go to the trouble of recording temperatures and making ventilation maps, showing the direction of the air currents, etc., all of which data are necessary before a satisfactory system of either natural or artificial ventilation can be planned. As most of the Western mines are in hilly or mountainous situations, it is generally easy to provide two openings at greatly different elevations, so that the heating effect of the workings can be depended upon to control the direction of the air currents to such an extent as at least to cool and ventilate the workings partly. When these advantages cannot be obtained, centrifugal or forced-draft blowers, driven either by steam or by electricity, furnish an easy means of obtaining the desired results. The latest high speed electric direct-driven centrifugal compressors give pressures up to 45 oz., and have been built in sizes up to 40,000 cu. ft. of free air per minute; but there is apparently no limit to the size of the machines which can be built under this system.

Tunneling.—As the United States continues to grow in wealth and importance, tunneling operations increase in like proportion, both in number and in magnitude. New York City and its environs are now underlaid by a network of tunnels, and other cities are rapidly developing underground systems, since through the increase in population business and travel become congested. All over the United States water supply, hydro-electric power, and the reduction of grades on railways are requiring new and expensive tunnels, to which, in the West, are added the great irrigation tunnels called for in both Government and private enterprises. The result of all this activity in tunneling has been a vast improvement in both machinery and methods, and a greatly increased number of thoroughly trained and skilled workmen, so that records formerly unattainable in the United States are now being made in widely separated localities.

Dredging.—Chain-bucket dredging for gold was first attempted in 1867 in Otago, New Zealand, and the first steam actuated dredge operating on this principle was built on the Molyneux in 1881. From a few small dredges copied after those in use in New Zealand, gold dredging in this country has grown into a great industry, which is carried on successfully from the frozen gravels of the Arctic to the sun

scorched riverbars of the tropics, and at all altitudes from 10,000 ft. down to sea-level. Under stress of competition and the necessity of meeting new conditions, dredges have grown both in capacity and efficiency to a point not even dreamed of a few years ago. Dredges are now built with close connected buckets, of capacities up to 13.5 cu. ft., and capable of handling 10,000 cu. yd. of gravel in 24 hr.; some have been built with bucket-ladders capable of digging 67 ft. below the waterline and 20 ft. above it. A new stacker now under construction will deliver tailing 160 ft. away from and 60 ft. above the deck of the boat. Improved construction and better man-

Gold-Washing in the Middle Ages, (From Agricola)

agement have rendered dredging operations less dependent upon weather; and last winter in Colorado a dredge was operated continuously at an altitude of 9990 ft. where the temperature on several occasions fell to 20° below zero.

Electric Transmission.—No sketch of this kind would be complete without some notice of the immense service which the mining industry is receiving from long distance electric transmission. While a few mines are favorably situated for the utilization of adjacent water power, many of the principal mining districts of the United States are at altitudes so great that any available water power is far below them. Again, as in the case of Nevada, Arizona, and portions of Utah, the mines occur in an arid country where it is difficult to obtain sufficient water for domestic purposes, to say nothing of power. Already the electric current is carried to all elevations from sea-level to timber-line, and there is scarcely a desert

mining camp of sufficient size to justify the erection of a pole-line that is not equipped with electric power. The ease with which this overcomes the old and apparently insurmountable problems of scarcity of water and fuel constitutes one of the delights of modern mining. The use of electricity has also completely solved the old vexed problem of underground sinking and hoisting, so that these operations are now as readily carried on from deep tunnel levels as from the surface. Transmission lines of all lengths up to 220 miles are in daily use, with carrying capacities ranging up to 40,000 kw. Long-distance transmission systems are in many cases operated at 100,000 volts, and new lines are building to utilize even higher pressures. Recent improvements in insulation promise to make still higher voltages possible, which would mean a corresponding increase in the distance to which current could be profitably carried.

Sampling.—Few departments of mining engineering have shown greater advance than ore-valuation. In milling and concentrating plants, where fine crushing is a necessary preliminary, sampling is a comparatively easy and reasonably accurate operation, but where the ore is to be treated in the blast-furnace, crushing of any kind is objectionable and fine subdivision is prohibited. Forty years ago, for the valuation of coarse ore, 'grab' sampling was in common use, and this method was replaced in slow succession by Cornish quartering, fractional division, and split-shovel sampling. Then came automatic sampling in many forms, but all taking a portion of the ore stream continuously. In 1884 a new system of sampling was invented which automatically deflects the entire ore stream for a varying portion (usually one fifth) of the time into the sample division. Numerous different machines working on this principle are now in use; and these types of sampling plants have been perfected to such a degree that where the hopper ore-cars which are now coming into general use are employed, ore may be unloaded, crushed, sampled, and re-loaded into the outgoing cars, and the ground sample delivered in a locked steel box, without ever having been handled—the entire chain of operations being performed automatically.

Concentration.—The separation of valuable minerals from worthless gangue must have been one of the earliest operations in the history of metallurgy. Up to less than 100 years ago the pan, tub, and inclined plane, which are all so graphically illustrated by Agricola, continued to be the only devices in use. Hand-jigs were first introduced for the separation of coarser particles than could otherwise be handled, and the principles involved are in use today, although improved mechanical appliances have changed and enlarged operations to such an extent that the primitive origin would scarcely be recognized. About 35 years ago the use of air as a concentrating medium was successfully introduced, and, despite its many disadvantages, this system, assisted by numerous mechanical improvements, still exists and manages to hold its own where water is unobtainable or, for some reason, cannot be used. In skillful hands, some of the pneumatic separators give wonderful results, but the delicacy of the adjustments and the attendant

dust will undoubtedly prevent any extensive employment of this method. The pulsating water current recently applied by a distinguished investigator to the concentrating field has already won a place for itself in both sizing and jigging operations, and promises to become a most important factor in concentrating work. Specific gravity is, however, no longer the only principle taken advantage of in mechanical ore sorting. To these have been added magnetic and static electric separation, and many different methods based on the surface tension of water (with or without the assistance of oil or acid), resiliency, and affinity for grease. The latter method, used very sparingly in this country, finds its chief application in South Africa, where it is used in the separation of diamonds from other stones. The recent discovery by Kunz and Baskerville that the use of the ultra-violet light would enable an observer to determine by inspection, with reasonable accuracy, the percentage of willemite in tailing from concentrators, has already found commercial application on a very large scale, and opens up a wide field for speculation as to what the future may hold in store for us in this field. The enormous size of some of the new concentrating plants erected in the West exemplifies in a marked degree the magnitude of the operations now being carried on. At Anaconda, Montana, the Amalgamated Copper Co. has an eight-unit concentrating plant, each section of which handles 1000 tons in 24 hr.; and some of the new plants at Ely, Nevada, and Garfield, Utah, are but little smaller in size.

Roasting for Blast-Furnace Smelting.—The earliest roasting furnaces to prepare sulphide ores for blast-furnace smelting were small hand operated reverberatories, with or without fusion hearths. These were followed by revolving cylinders and various types of mechanically operated reverberatory furnaces, all of which were not only expensive to operate and keep in repair, but yielded a product very badly adapted to blast-furnace work. Today these old fashioned furnaces, both hand and mechanical, have been almost entirely superseded by blast systems like the Huntington-Heberlein, Carmichael-Bradford, and Savelberg, which make it possible to utilize the many advantages of blast-furnace smelting for the treatment of concentrate, fine ore, and flue-dust at very low preparatory costs. These systems marked a wonderful advance over the old reverberatory roast with its pulverulent product; but they were still open to the serious objection of requiring a large amount of manual labor in charging and discharging the pots and breaking up the sintered product. In spite of this drawback, the results obtained were so desirable that study and invention along these lines have been stimulated to such an extent that there are already in use mechanical roasting and sintering-plants (system of Dwight and Lloyd), to which ore can be fed in a steady stream, and which will automatically deliver a desulphurized, sintered, and broken up product in the best possible condition for blast-furnace work.

Lead Smelting.—Progress in this department of metallurgy during the past decade, in the West, has been much hampered by three conditions: (1) all the lead smelting plants operate almost entirely on

custom ores; hence the supply is irregular in volume, grade, and composition; (2) the great extension of the leasing system throughout the West tends to bring ore into the market in very small lots, thereby increasing the difficulties and cost of storage and bedding; (3) eight years ago nearly all of the principal lead smelting plants in the United States passed into the hands of a corporation organized for that purpose, and the industry was thereby deprived of the stimulus of healthy competition. The largest lead furnaces in the United States have hearths 180 by 44 in. and treat daily from 150 to 225 tons of ore, according to its character. Mechanical charging is used in some cases; but while it slightly reduces operating costs, it is no improvement metallurgically. In Australia, where different conditions prevail, the improvements in lead furnaces have kept pace with those in iron and copper smelting.

Reverberatory Copper Smelting.—In 1867, when Richard Pearce (afterwards president of the Institute), built his first reverberatory furnaces at Black Hawk, Colorado, they were considered the acme of metallurgical perfection, and their successful operation did wonders for the mining industry of the State. The hearths of these furnaces were only 8 by 12 ft. in size, and their daily capacity was 12 tons. As the quantity of ore produced increased and the necessity for handling larger tonnages became apparent, the reverberatory furnaces have been steadily enlarged and improved, until today they have attained almost incredible dimensions, having a hearth area of 19 by 116 ft., and a daily working capacity of more than 300 tons, which, in the case of easily smelted ores, has risen to over 400 tons. These large furnaces secure great saving of heat and uniform, continuous operation, for reasons into which I need not enter here.

Blast-Furnace Copper Smelting.—The early water-jacketed blast-furnaces for smelting copper ore were small, round, wrought-iron affairs, about 30 in. in diameter, and rarely smelted more than 12 tons of ore in 24 hr. From this puny beginning, keeping pace with the rapidly growing copper industry of this country, furnaces have increased steadily in size and improved in mechanical construction, until they have reached the enormous dimensions of 87 ft. in length by 4 ft. 8 in. in width, with a daily smelting capacity of 3000 tons of charge. These furnaces are mechanically fed, work under an air pressure of 40 oz., and give infinitely less trouble than their smaller progenitors. The water-jackets are completely sectionized, and it is possible to renew most of the sections without stopping the furnace. At first only one tier of jackets was used, then two tiers came into use, and now some of the most recent furnaces have air or water-jackets replacing the brick superstructure, thus doing away with much of the roof accretion nuisance. On furnaces built with a crucible, baby water-jackets have replaced the old cast-iron plates, and water-jacketed nose pieces have greatly lengthened the life of the furnace discharge spouts. The credit for the latest improvements in design and increase in size of both reverberatory and blast-furnaces is due principally to E. P. Mathewson, whose untiring energy as an investigator and skill as a metallurgist have made the Washoe plant, at Anaconda,

the Mecca for progressive engineers from every country. The recently invented acetylene blow-pipe promises to be of great service to blast-furnace engineers, as through its use it will soon be possible to obtain welded water-jackets entirely free from the objectionable lap seams and rivets.

Electrical Smelting.—A great amount of experimental work has lately been carried on by engineers in various parts of the world having for its object the utilization of the electric current in metallurgical operations, and there is no doubt that in the near future many minerals now smelted with fuel will be reduced to metals by electrical processes. The electric current possesses the great advantage of allowing a most efficient utilization of the heat; and also complete control of the exposure of the molten metals to air or gases.

Briquetting.—At many blast-furnace plants the fine is made into briquettes with the ordinary die-and-plunger machines; but if free acid or copper sulphate be present, the surfaces of both dies and plungers are rapidly corroded, which obviously increases the diameter of the dies and diminishes that of the plungers. As this solvent action continues, a point is soon reached when the plunger no longer fills the die opening, and pressure forces the material through the space between them, instead of consolidating the mass. When a sufficient amount of plastic material, such as slime, can be obtained to mix with fine ore and flue-dust, so as to give the mass the property of flowage under pressure, it may be briquetted in machines similar to those used in making building brick by the 'stiff-tempered' process. Solvents do not interfere with the operation of these machines, and by constructing the working parts of steel and phosphor bronze, it is possible to make briquettes dry enough to pass directly into a blast-furnace at the rate of 600 to 800 tons per day for each machine employed, at a cost of less than half that of the die-and-plunger system.

Chlorination.—Chlorination is confined almost entirely to sulphide gold ores having so little silver that its loss may be disregarded, and which require a preliminary roasting before treatment. The early methods of tank leaching have been superseded by barrel chlorination, and in some of the latest plants chlorine is produced by electrolysis instead of by the decomposition of bleaching powder with sulphuric acid. The largest plants operating under this system treat custom ores, and the stress of competition, together with the necessity of handling constantly increasing tonnages, has brought about great improvements in both machinery and methods. The most desirable features of this process of gold extraction are the high percentage recoverable, and the rapidity with which clean-ups can be made, rendering it easy at all times to know exactly what results are being obtained. The largest plants operating under this system are situated in Colorado City, Colorado, where two mills owned by one concern have an aggregate capacity of 800 tons per day.

Cyanidation.—While the first patent for extracting gold from its ores by cyanide solutions was issued in 1867, it was not until McArthur and Forest took it up in 1889 that practical results of any value

were obtained. Since that time the use of the process has increased by leaps and bounds in all of the principal gold producing countries, and today it is the principal factor in the world's steadily increasing gold production. Cyaniding seems to work with equal facility on raw ore, roasted ore, and tailing, and with the steady improvement in the mechanics as well as the chemistry of the process, it bids fair to do even greater things in the future than it has done in the past. Nor is its use confined entirely to the extraction of gold. In many districts it is operating with great success on mixed gold and silver ores. At Millers, Nevada, two plants with an aggregate capacity of 700 tons per day are operating on Tonopah ores, in which the average ratio of silver to gold is 80 to 1. The largest and perhaps the most complex cyanide plant in the United States is the Golden Cycle mill, at Colorado City, Colorado, which has a daily capacity of 1000 tons, and treats exclusively Cripple Creek ore, all of which requires careful roasting and very fine crushing. The Homestake cyanide mill handles a larger tonnage, but treats only tailing. Next to this plant in point of size and importance, and handling ore of much higher grade, is the new mill of the Goldfield Consolidated Co., of Nevada, which has a capacity of 600 tons per day, and contains the very latest improvements, culled from American, African, Australian, and Mexican practice.

Fume Recovery.—No department of metallurgy has made slower progress than this most important division, but now, through an unholy alliance between the unscrupulous contingent fee attorney and the greedy land owner, the success of 'smoke-farming' is compelling the smelting companies to do for self preservation something which they should long ago have undertaken for profit. Out of the almost numberless devices which have been tried for fume recovery, the bag house affords the best solution of the problem yet devised. Bags were used for the recovery of both zinc oxide and lampblack more than 50 years ago, but were not used for fume recovery until 1878, when Bartlett set up a small plant at Portland, Maine. The first large successful installation of this kind was erected by the Globe Smelting Co., in 1885, and has been in continuous operation ever since. While the bag house has been eminently successful in the recovery of blast-furnace fume, it cannot be used on fumes from reverberatory roasting or smelting furnaces, owing to the fact that a portion of the sulphur dioxide formed by the oxidation of the sulphur is raised to sulphur trioxide by contact with incandescent ferric oxide. At the United States Smelting Works, in Utah, provision for protecting the bag house from sulphur trioxide is made by blowing into the flues zinc oxide, which immediately absorbs the sulphur trioxide present to such an extent that it has been found quite possible to use cotton bags. The bag house has proved very efficient in recovering fume from lead refineries and all lead smelting operations excepting roasting. In large copper smelting plants, where large volumes of gas are produced carrying a sufficient amount of sulphur trioxide to destroy woven fabrics, three systems are in use—namely: radiation, decreased

velocity, and friction—and in many cases two or more of these methods are combined. At the Washoe plant, in Anaconda, long steel covered flues of enormous cross-section have been installed for a number of years, and, while this system does not effect a complete recovery of the fume, it is as nearly perfect as it is possible to make a plant today. At Great Falls, Montana, the Boston & Montana Co. is installing the friction system at a cost exceeding \$1,000,000, which includes the construction of a stack 506 ft. high and 56 ft. in diameter and a dust chamber in the flue system, of such width that the furnace gases will pass through it at a velocity considerably less than 500 ft. per minute. From the roof of this flue chamber more than a million steel wires will be suspended, an arrangement which experiment has shown to increase greatly the settling efficiency of the dust chamber. This installation is practically completed, but it will be some time before the results obtained can be accurately determined. I need not add that where (as in some Eastern works), metallurgical and commercial conditions permit the manufacture of sulphuric acid from the fumes, this method offers special advantages.

Conclusion.—The subjects already alluded to occupy but a small portion of the field covered by our 4000 widely scattered members, but I hope that enough have been mentioned to serve as topics for discussion at this meeting. The ever widening range of operations, the constantly expanding magnitude of mining undertakings, and the continually increasing complexity of both machinery and methods are daily creating new openings for mining engineers. To meet this demand our technical schools and colleges are yearly sending out an increasing number of graduates, whose opportunities and responsibilities will be even greater than those of the engineers controlling the activities of today. Even now, one change very much to be desired is beginning to become apparent. Heretofore it has too often been considered that an engineer's accountability ended when he discharged his full duty to his employer. Today we are beginning to realize that the public forms a third party, vitally concerned in the results of the work in which mining engineers are engaged. As large investments are usually held by divided ownership and stocks are often scattered far and wide, so that the owners of small holdings have little or no opportunity to become conversant with the exact conditions of the properties they represent, an engineer's first duty should be to see that no word or act of his can be construed so as to give one man an opportunity to take advantage of, or mislead, another. Everyone, no matter what his station, has a duty to society and his fellow men which can never be either ignored or neglected. The employer, whether an individual or a corporation, is entitled to all of the information and data which experience, diligent investigation, and careful study can bring to light, and while an engineer has a right to state probabilities from both indications and analogy, he should never assume the gift of prophecy and thereby delude both himself and others. Finally, a career has been a failure except one can say 'No man is poorer because I am richer'.

GAS ENGINES.

Written for the MINING AND SCIENTIFIC PRESS
By MARK B. LAMB.

When it pays the Steel Corporation to use gas instead of steam engines, though coal costs it far less than it costs the metal miner of the West, it would seem advisable for the latter to at least look into the matter. The huge steel plant at Gary, Indiana, has a number of such gas engines deriving their power from blast-furnace gas of low heat value, which would otherwise be burned under boilers with much less economy. The purchase of this equipment of gas engines was the largest single order for this class of engines ever placed in this country and was for the largest engines of this type ever built. The steel in-

tion alone required 2300 freight cars for its transportation.

The gas supply for these engines contains 27% CO and the estimated 45,000,000 cu. ft. daily capacity of the battery of blast-furnaces would generate 500,000-hp., if used exclusively in gas engines. Accompanying diagrams show graphically the great difference between gas and steam engines as regards thermal efficiency. Tests of the engines already in operation show an actual thermal efficiency of 23 to 24% and better results are expected when the complete plant is in operation. Of the amount of gas stated above, only 57% is destined for use in the engines, the remainder to be used for the various heating processes in the plant.

One great improvement in the design of the mod-

Cylinder-End, Gas Engine Frame, 2500 Kilowatt Unit.

dustry of this country as a whole is today operating gas engines totaling 400,000-hp. A few years ago it was the fashion to decry the conservatism of American steel makers while lauding the Germans. Now the conditions are reversed and though the manufacturer here has been slow in accepting the gas engine, he has profited by the experience on the other side.

The Gary plant of the Steel Corporation includes 33 of the largest units. Of these, 17 are twin engines with four cylinders 44 by 54 in. They are of the four-cycle, double-acting type, and the arrangement of the cylinders gives two impulses per revolution. The 17 are direct connected to 2500 kw. alternators. The other 16 provide compressed air for the blast-furnaces and are direct connected to 'Slick' blowing 'tubs' of special design. They deliver 30,000 cu. ft. of air per minute each against 18 lb. pressure. A total of 150,000-hp. of these engines has been ordered to date. The shipment to the Steel Corpora-

ern gas engine is shown in these machines in the perfection of governing and of uniformity of revolution attained. For the work of running alternators, governing must approximate perfection. Compressed air is used for starting, and on account of the four cylinders the start can be made from any position. Even with the tandem, double-cylinder unit engine, the high compression prevents the engine from stopping on the center, and no difficulty is experienced in starting.

The cleaning of the gas has been given careful attention. The Thiessen washer is one of the interesting machines of this series. Briefly, it consists of an outer cylinder and an inner revolving drum. The inner drum is provided with vanes which throw the gas against the inner surface of the cylinder which is kept continuously flooded with water. The last remaining particles of dust are thus thrown from the gas against this film of water, and removed.

Although, as has been said, this group of engines

is the largest, nevertheless, a multitude of power users are saving by means of producers and gas engines. The Port Washington, Wisconsin, power-plant of the Milwaukee Northern Railway Co. has two double-acting, twin, tandem gas engines of 2000-hp. connected direct to two alternators. The valve-gear is of the standard A-C Co. stratification type, the engines operating with constant compression and governing by variation of the amount of gas admitted. A modern Loomis-Pettibone producer-plant furnishes a gas of 125 B. T. U. per cu. ft. The producers operated with a down-draft avoid the use of an auxiliary equipment for extracting tarry products from the gas. Any soot which is formed in the gas of such a producer is removed with much less difficulty. Such a producer makes a gas containing over 80% of the heat units contained in the fuel used. In the every day operation of the plant, reverse runs of steam are made at regular intervals, which adds a quantity of water-gas of high heat value to the gas-holder mixture. The effort with all producers using coke and charcoal is simply to reduce as large a proportion of the fuel to CO as is economically possible. The less the fuel burned to CO₂ and the less the radiation and other heat losses, the higher the efficiency. When wood, peat, lignite or bituminous coal is used as fuel, part of the gas produced consists of hydro-carbons, varying in formula with the chemist analyzing. Besides the combustible constituents of the gas, nitrogen and carbon dioxide are present.

As the smaller engines, ranging from 200 kw. capacity upwards have been placed on the market, power users, other than street railways, have begun to appreciate and obtain the advantages of this method of generating power, and it is such moderate sizes which are of special interest to the mine and plant operator of the West, of Mexico, of Africa, and of other places where fuel is expensive. A number of power plants consisting of several such engines are in use. The plant at Santa Barbara, Chihuahua, was at first operated on imported coal of various grades. Finally it was found that native fuel was suitable, and at times the plant has even operated on wood-gas exclusively. The same may be said of the gas engines at Nacozari, in Sonora. At the Waihi G. M. Co.'s plant in New Zealand, five gas engines of moderate capacity (200-hp.), operating on producer-gas have been placed in the Waikino mill, besides numerous smaller engines, and a pumping-plant, including two 370-hp. engines, has been ordered.

It should be noted as an important consideration in the decision as to the suitability of gas engines for any particular work, that on account of the necessity for cleaning the electrodes and cylinders at intervals, it is better policy to divide the power-load between several engines, rather than to be obliged to shut down the plant for this necessary cleaning, unless there are regular stoppages for other purposes. As such units can be obtained in any desired size up to many thousand horse-power, the question of relative cost is alone involved.

For the mining power plant, a gas producer is a necessary part. The producer is now made so simple, effective and automatic that the troubles which the

gas engineer experienced in the past have been practically eliminated. For the smaller sizes, suction producers are reliable and less expensive. For the larger sizes the pressure producer is favored. The choice is largely a matter of local conditions, a fact occasionally proven in a most practical manner. For example, the blowing section of a producer in a plant containing several 2000-hp. engines was put out of commission for several hours by a careless employee. Until the necessary repairs were made the gas plant delivered its product to the engines as a suction producer, with no ill effects or difficulty.

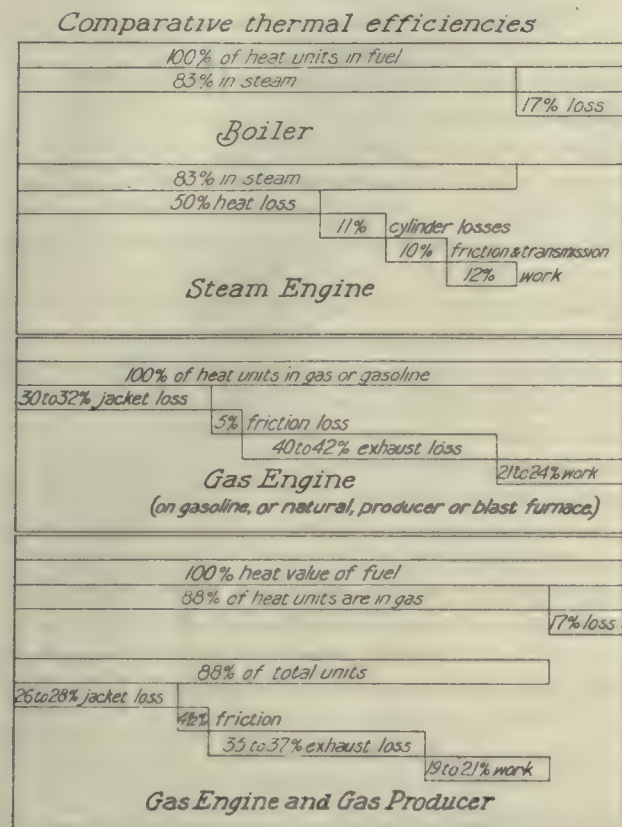

Although in the majority of cases in the East, coal or coke is used in the producer, plants of 100-hp. and over are running in many parts of the world using wood as fuel. A bed of incandescent coke is maintained in the bottom of the producer as a final 'fixer' of the tarry products distilled from the wood. The simplest form of suction gas producer (in which the gas is taken from the top of the fire and is, therefore, not obliged to pass through an incandescent bed), must be fed with fuel which produces no considerable amount of tarry or other condensable gas.

In Europe it is customary to grade coal for producers between $\frac{1}{2}$ and $1\frac{1}{2}$ in. in size, which adds somewhat to the cost of the fuel. Where charcoal is used in small plants it is best to seive out the fine coal and dirt, in this way reducing the dust taken up by the gas, as well as the amount of clinker and ash. In addition, the fire burns more nearly evenly, and for a longer time without cleaning. A suction producer and engine of 115-hp. is operating in South Africa, 130 miles from the railway. The fuel is charcoal and 1-hp. per hour is regularly developed with from 1 to 1.25 lb. of fuel. The engine runs a rock-breaker, crushing-rolls, elevators, screens, jigs, Wilfleys, pumps, etc., for a copper concentrator and its regulation is reported to be perfectly satisfactory.

The general design of the Gary engines can only be lightly touched upon here. The most striking feature is the massive frame. This frame alone weighs 100 tons, and the factor of safety used in the design of the strain-resisting parts is so large that the normal load is but a small part of the total strength of the machine. Although the shaft of the direct connected engines, which must carry the weight of the revolving field of the alternator, is 3 ft. in diameter, the lower shell of the main bearing is provided with a spherical seat to allow for deflection of the shaft. The deflection of the piston-rod under the weight of the huge piston is met by giving the rod a slight initial camber. All surfaces exposed to the ignited charge such as cylinder walls and heads, piston, piston-rod and exhaust-valve, as well as the lower shells of the main bearings, are water-cooled. The valve arrangement is simple with the inlet valve on top and the discharge below. The timing of the air and gas valve is such that sufficient air is first admitted to clear the cylinder, then gas and air follow, and finally the gas valve closes first, thus permitting a layer of air to lie between the explosive charge in the cylinder and the inlet valve. Two independent electrically operated igniters are fitted into each cylinder near the heads. The timing of these is taken care of by sets of brushes bearing on make

and break collector rings mounted on the eccentric shaft, and regulated by a single hand wheel.

The Western lignite, owing to difficulties in firing it successfully, is not suitable for use under boilers,

but is entirely satisfactory in producers designed for its use. One horse-power can be delivered from two pounds of such fuel when it is used in a gas producer and gas engine. In fact, the manufacturers of producers are now successfully gasifying practically all

plant (per 24 hours and based on 3% charge), is 275-hp. At this rate the possible development of power at the various copper smelting plants in the United States, which operate under similar conditions, can be readily estimated.

All over the West occur opportunities for large saving in fuel cost and as the gas engine has now passed the experimental or uncertain stage in its development, there is no good excuse for failure to use it extensively. The manufacturers will now supply the engines and alternators and guarantee results, which is all that the steam engine manufacturer can do, and in fact, is all that he is asked to do.

APPLICATION OF STEEL TO MINE TIMBERING.

By R. B. WOODWORTH.

*The use of steel for the construction of tipples, smelting houses, boiler houses, and the like, in above-ground construction, is not new. It came into use early in the history of extensive mining operations in the United States. The use of steel in constructions of this character is subject to well-known laws such as obtain in the design and use of mill-buildings, boiler plants, and other structures. There are special considerations in connection with the use of steel underground for gangway supports, pump stations, and so forth, where temperature-conditions are different and where the loads to be carried must be investigated in the light of experience rather than from determinable principles of engineering design.

The first use of steel for the support of roofs in mining operations, of which I am aware, was in 1878, when it was attempted to use old rails as head-pieces in the mines of Commentry, France. The best results were obtained when they were placed edge-ways, but they were liable to breakage. Iron bars of rectangular section 3.15 by 1.18 in. by 12 ft. long were ultimately adopted in preference to rails and other sections, as they are easily straightened, and great rigidity is not necessary. In 1889 some of the bars had been re-used 200 times. Breakages were rare, as iron or steel bends under stress before it breaks. The roof in this mine was probably of first-class character, otherwise, owing to the weakness of the form of section employed, the sections in use would not have given the satisfaction which they seem to have rendered. Previous to 1884 old iron and steel rails had been used at the Thorncliffe collieries in England, but about 1884, according to *The Journal of the Iron and Steel Institute* for 1887, I-beams of mild steel were installed in these collieries for props and roof-supports, and their behavior is noted with great satisfaction. At these collieries it was difficult and expensive to maintain a gang-way with wood, and it was noted that the steel-beams proved to be much better than iron or steel rails. They did not break as often but would bend 9 in. in the centre of an 8-ft. span without showing signs of fracture. "So far, out of some thousands in use, only nine have broken; of these, five were 10 ft. long by 6 in. deep, and broke without much deflection; one was 9 ft. long and 5 in. deep and broke with a deflection of 6 in; the remaining three were each 8 ft. 6 in. long and 5 in. deep, and were considerably bent before breaking." This experience is in line with sound engineering principles which demonstrate conclusively that for roof-supports the I-beam is the ideal form of section. In 1888 iron and steel frames had been installed in the Creusot mines in France, the Prussian Government lead mines in the Harz mountains, the Altenwald coal mine near Saarbruecken, Prussia, and the Segur mines in Austria, and since that date the use of steel in the English and Continental mines has had a continual and satisfactory development. The advantages in their use as compared with wood,

apart from considerations of fire protection, were their greater durability, the possibility of re-use, lightness and handiness, increased space for ventilation, and less deterioration of the air of the mine from decaying timber.

The earliest use of steel in the mines of the United States for roof and gangway supports followed the lines of previous history on the Continent; that is to say, worn-out steel rails were used, to be followed in turn by steel beams supported on masonry, or on solid coal, or on timber supports embedded in the coal. The Carnegie Steel Co., in 1894, made designs for the substitution of steel in place of wood in the lighter operations, but the first use of square timber-sets of structural shapes for main headings seems to have been in 1897 at Stearns' shaft, Susquehanna Coal Co., Nanticoke, Pennsylvania, under the supervision of R. V. Norris, consulting engineer. These timbers were put in 540 ft. below the surface, and the conditions which caused their use were the large spans at the foot of the shaft and the great pressure under which 24 in. yellow pine timber collars lasted only about 8 months. This steel is still in position, and in excellent condition, exposed to constant contact with mine-water, without signs of failure or corrosion, and without other protection than good heavy coats of paint.

About 1897 the Lehigh Valley Coal Co. also installed at the Hazleton shaft colliery, No. 40 slope, under the supervision of S. D. Warriner, chief engineer, and W. A. Lathrop, general manager, a pump-house framed with square timber-sets composed of 12 in. 35 lb. beams, connected by castings, and lagged with old rails. This pump-house is 51 ft. 3 in. long by 24 ft. 5 in. wide, and shelters a Corliss cross-compound surface-condensing pumping-engine of 35,000 gal. capacity per minute, under a steam pressure of 100 lb. per sq. in. and 550 ft. vertical head. The pump-house is in the bottom rock of the Wharton vein, 1085 ft. above sea level. Since 1897 the success which has attended the installation of steel gangway supports has led to a gradual increase in the number of installations, and in the last two or three years more rapid progress has been made by reason of the introduction of forms particularly adapted for use as legs of the square timber-sets, props, and the like. As already noted, early experience indicated that the standard I-beam was the section best adapted for collars and for roof-supports generally, as this form of section combines a high degree of resistance to bending, with a minimum of material. It is not, however, suitable for use as the legs of the square timber-sets, or as isolated props, by reason of the fact that the radius of gyration of the section is low, and it is not, therefore, adapted to resist compressive strains, to sustain which a shape is needed equally strong about both axes of symmetry. Hollow tubes possess these requirements in a theoretically ideal manner, but suffer from the disadvantages of relatively high cost, and the difficulty of making proper connections, which have practically prohibited their use in building constructions above-ground except those of the simplest character. For the legs of the square timber-sets, and for the isolated mine-props, the ideal

*Paper read before the American Mining Congress, Goldfield, Nevada, September 27, 1909.

rolled section of sufficient strength for most ordinary conditions is given us in the H-section, a form of rolled shape which possesses a large radius of gyration, and the most economical distribution of material in comparison to its weight. The first manufacturer to furnish these in the United States was the Carnegie Steel Co., and its 4, 5, 6, and 8 in. sections have been designed as the result of careful investigation into mining conditions with an especial view to use in mining operations. The 4 in. section, first rolled November 11, 1907, weighed 13.6 lb. per lineal foot, and is equivalent in strength to an 8 in. yellow pine timber; the 5 in. section, weighing 18.7 lb., first rolled December 4, 1907, the 6 in., weighing 23.8 lb., first rolled August 23, 1907, and the 8 in. section, weighing 34.6 lb., are equivalent in strength to 10, 12, and 15 in. round southern yellow pine timbers. Experience in their use has demonstrated that it will seldom be necessary to go beyond this range of sizes.

As already noted, steel was first used for roof-supports in the form of rails, to be followed by rectangular bars, and finally by the standard I-beam supported on the coal, or on the rock, or on short wooden posts, or, as is quite common in the permanent gangways of the English mines, on long walls built from waste rock or brick. An example of this latter form of construction is to be found also in the Leggitts creek colliery, Delaware & Hudson Co., Scranton, Pennsylvania. This is the simplest use to which steel can be put in the mines, and noteworthy examples are to be found in the bituminous fields of southeastern Ohio. At the Boggs mine, of the Youghiogeny & Ohio Coal Co.'s No. 3 mine, at Barton, Ohio, a similar installation is in place on an entry 16 ft. wide, in most cases 6 in. beams being used, and taking the place of 10 by 12 in. timbers, the average life of which is only one and a half to two years. At drift No. 1, Roby Coal Co., Adena, Ohio, steel is being used to form a permanent gangway 9000 ft. long, the construction being similar to that followed in the mines of the Youghiogeny & Ohio Coal Co. In cases where the coal is good and solid, and not liable to crush, this simplest form of construction finds ready use, places of unusual weakness being taken care of by short timber-posts supported on props of longer or shorter lengths as conditions may require to obtain solid bearing. It may be said that there is a divergence of opinion as to the propriety of supporting beams directly on the solid coal, and in some States that form of construction is not acceptable to the mine inspectors. At all events great care should be exercised not to permit any excessive loads to come on the coal.

The next simplest form for the use of steel for gangway-supports is to be found in an installation made at the Adrian mines of the Rochester & Pittsburgh Coal & Iron Co., Punxsutawney, Pennsylvania, where 50 tons of 4 in. H-sections 13.6 lb. per foot, are used to replace wooden timbers 8 in. square. These H-sections are spaced 4 to 5 ft. centres and are supported at their ends on round timber-posts, making a very solid and substantial construction. In this mine the question of head-room was of prime consideration, and the additional 4 in. gained by the use of steel was an item of the utmost importance. The

4 in. H-sections used in this mine were the first of this size rolled in the United States.

In the form of construction originally designed by R. V. Norris for the Stearns shaft, Susquehanna Coal Co., Nanticoke, Pennsylvania, the collar is composed of a standard I-beam which frames at each end between two channels separated by gas pipe separators and resting at their bases on a cast-iron shoe of circular form which in turn fits into a cast-iron base. Pin connections are used at the top of the legs, one passing through the beam and channels and the other through the channels only; steel wedges are driven under the collar so as to distribute the weight on both pins. In this form of construction, for a standard single-track gangway, it is necessary to assemble 31 pieces; in ordinary practice these are bought from the different makers and the cost of this form of timber is comparatively high. An installation of this character, however, can be adapted to almost any requirement of strength and the largest stretches of steel timber gangway work in the anthracite regions are timbered after Mr. Norris' design. The Summit Branch Mining Co., for example, has a single stretch of 1500 ft. at its Williamstown, Pennsylvania, colliery, while other long stretches are to be found in the mines of the Lytle Coal Co., Minersville, Pennsylvania, Lykens Valley Coal Co., Williamstown, Pennsylvania, and the Windber mine No. 36, Berwind-White Coal Mining Co., Windber, Pennsylvania. In the latter installation the collars are 12 in. beams 12 ft. long; the legs are composed each of two 8 in. channels and the cotter-pins are $1\frac{3}{4}$ in. diam. The cast-iron bases rest on brick piers 18 in. square, and the lagging is composed in part of 30 lb. rails and in part of timber. The plain material was bought from the rolling mill and the fabrication was done in the shops of the Berwind-White Coal Mining Co. Observation and experience, however, indicate that inasmuch as wood gangway-supports used in square timbering are not adjustable, it is needless and uneconomical to provide adjustability in steel mine timbers, consequently different designs have been worked out by which the use of rocker-castings at the bottom and pin-connections at the top have been eliminated. Sets have been constructed of various modifications between these limits, the simplest form in which the double channel-leg can be used in combination with an I-beam collar, in which the two channels forming the legs are connected in the shop by bolts and separators. They carry angle-brackets at their tops, on which the beam rests, and to which it is connected by bolts to permit easy removal, and they rest at their bottoms on steel-plates to which bars are riveted forming slots for holding the channels in position. In this form of construction, when the material reaches the point of erection there are only five pieces to take care of; the single beam-collar, the two legs, and two base-plates. If the footing is good, even the base-plates can be eliminated. The angles riveted to the webs of the channels transmit the load from the collars to the legs, and the bent angle-brackets prevent undue side motion.

In the large majority of cases and up to the limit of their strength the H-sections will be found the ideal form for simplicity and economical construc-

tion. The simplest form adapted for square timber purposes consists of a beam-collar, two H-section legs with lug-angles at the top to prevent side-motion, and absolutely plain plates for bearings. If the plain plates are omitted, there are practically three pieces to handle. The set can be put together on the ground, and raised into position with a minimum of difficulty and in this form the steel square timber-set is the exact equivalent of the three-piece wooden set in such common use. The first sets of this design used in the United States were installed in October, 1907, in the pump-house of the Midvalley Coal Co., at Wilburton, Pennsylvania, and the steady demand for them indicates their perfect adaptation for the usual purposes of timbering gangways. Examples of their use are now to be found in the mines of the Lytle Coal Co., Summit Branch Mining Co., Berwind-White Coal Mining Co., Alden Coal Co., Susquehanna Coal Co., Pine Hill Coal Co., and the Greenough Red Ash Coal Co. The bent lug-angle which prevents lateral motion may be replaced by a steel bar, and sets of this character may be found, among other places, in the Maxwell colliery of the Lehigh & Wilkes-Barre Coal Co. In fact the ease with which steel can be adapted to any condition of service is exemplified in the various simple modifications which have been made in the construction of mine-timbers.

In the endeavor to obtain adjustability in a simple way a steel gangway support has been devised in which a set consists of an I-beam collar and H-section legs connected to each other by rocker-castings, and resting at the bottom on a casting exactly similar to that at the top, allowing free motion both at the top and the bottom. There will be few cases, however, where it is necessary or desirable to go to this refinement in ordinary mine-construction. An example of its use, however, is to be found in the mines of the Copper Queen Consolidated Mining Co., at Bisbee, Arizona, 60 sets being installed in 1908. Examples are also to be found in the mines of the Delaware, Lackawana & Western Railroad at Scranton, Pennsylvania.

The forms of lagging for use with square timber sets vary, of course, with conditions in the mines and the materials readily at hand. In some cases short round poles are used, in other cases planks $1\frac{1}{2}$ to 2 in. thick which have served their period of usefulness outside, and in other cases old rails. An excellent installation consists in the use of concrete arches of slight depth, sprung in between the gangway timbers. Endeavors have also been made to lag with thin slabs of concrete made on wire netting, expanded metal, and other forms common in building construction. The most complete and modern installation, however, is to be seen in the pump-house at No. 5 mine, Pennsylvania Coal & Coke Co., Ehrenfeld, Cambria county, Pennsylvania. This pump-house is 36 ft. long, 19 wide and 13 high in the clear of roof-support collars. The framing is built up from 11 sets of mine timbers with 6 in. H-section legs and 6 in. H-section collars. The collar is supported in the middle by a 20 in. 65 lb. I-beam, which carries the trolley for handling all machinery, and rests on three 6 in. 23.8 lb. H-section posts at centre

and ends. The legs rest on concrete bases; between the legs and the collars are framed short lengths of 6 in. 12.25 lb. beams, and between the legs and the collars are framed short lengths of 6 in. 12.25 lb. beams, and the whole structure is covered completely by $\frac{3}{8}$ in. steel plates. These plates are cut to short lengths for easy assembling and are held in position by $\frac{5}{8}$ in. bolts. No wood being used in the construction of any portion of the pump-house, the structure is absolutely fireproof.

So far as isolated mine-props are concerned, I have been unable to learn of the use of steel in the United States, and would be glad to obtain detailed information on this application of steel to mine timbering. Timber conditions in the United States are such that it has been possible heretofore to obtain prop-timber in sufficient sizes and quantity for all practical purposes. In the English mines, however, forms of steel-beams approximating the H-section have come into extended use. In 1905, for example, the Sandwell Park colliery, West Brownwich, England, was using 5 by 4 in. beams with $\frac{1}{2}$ in. webs weighing 22 lb. per foot in lengths up to about 7 ft. for prop-purposes and 6 by $4\frac{1}{2}$ in. beams with $\frac{1}{2}$ in. webs weighing 26 lb. per ft. for roof-supports. At the Bargood colliery of the Powell-Duffryn Co. the props were made by cutting out the webs of the beams at each end for 3 or 4 in. back and bending the flanges over so as to form a bearing for the steel. This construction gave fair satisfaction, but suffers from excessive cost in manufacture. At other collieries the Mannesman Tube Co.'s system of collapsible tubes was in use. These tubes are made in two parts, the top section fitting inside the bottom, and are held in place by set-screws and other devices, giving a strength up to 16 tons direct compression. Many devices have also been patented in the United States to accomplish the same purpose, most of which, however, are based on ideas involving large expense, and all departing from that simplicity which is found in the use of wood. The forms of mechanical prop used in German mines are made in a collapsible form, and the cost is practically prohibitive so far as American conditions are concerned. It does not seem to be necessary to provide much variation in the length of props, and the simplest and cheapest form in steel which can be devised under present mining conditions is an H-section cut to length resting on a $\frac{1}{4}$ or $\frac{3}{8}$ -in. plate on the floor, and having a similar cap wedged against the roof by wooden wedges, or the H-section may bear against wooden blocks at each end.

So far as I am able to ascertain there are no well-defined rules by which the strength of square timber-sets or props may be calculated, and conditions in the mines vary so much that no set rules can be laid down. Experience governs the use of wooden mine-timbers in such conditions as timbering is required, and experience in the use of steel must necessarily follow experience in the use of wood. Tables of equivalent strength of wood and steel beams, columns, and so forth, enable the designer readily to substitute steel for wood in existing operations. In new operations the design must follow observed conditions elsewhere, but at all events the variety of

sizes and weights rolled by the steel makers is sufficient to permit a close approximation to the strength desired, so that there may be absolutely no waste of material. There is this difference between the behavior of steel and wood under service-conditions: steel deflects gradually under pressure, and will bend greatly before breaking; indeed unless there are defects in the steel itself, there is no reason at all why a steel-beam should break under any conceivable load in the mine, whereas wood, in addition to the pulling apart of the fibres longitudinally, will also break transversely. As a consequence of this difference in the behavior of the material, wood, which has been in place and is overstrained, is worthless; the steel which has deflected so far as to decrease the head-room in the roof-supports below the clearance-lines may be taken out, straightened, and replaced. Some of the bars in the Commentry mines, France, have been used 200 times. Another item of consideration is the fact that under temperature and moisture-conditions wood rapidly deteriorates, while steel remains unchanged, except so far as it may be liable to the ordinary processes of corrosion.

A pound of steel in beam-shape is, roughly speaking, equivalent in strength to a board-measure foot of the best southern yellow pine or white oak, and under present market conditions the cost of steel in Pennsylvania is about twice the cost of the wood used in square timber-sets, so that if the first cost of the installation is considered, the advantage will lie with the wood. Where, however, the gangway has to be maintained over a number of years, and the workings are in any sense permanent, the steel is economical on the basis of ultimate cost by reason of its long life and endurance. In the Maxwell colliery of the Lehigh & Wilkes-Barre Coal Co. double-track gangway-sets, consisting of 24-in round yellow pine collars 17 ft. long, with legs 10 ft. 6 in. long, weighing approximately 6280 lb., needed replacement in 2½ years. The cost of the timber-set was about \$10 for the timber, or \$15 erected. These sets were replaced in 1908 by 20-in. 65-lb. beam-collars and 8-in. 34.6-lb. H-section legs. The cost per set erected on concrete bases was \$40. At the lowest assumption the steel should last 15 years, whereas during the same length of time six wooden sets would be required. Capitalized at 8% compound interest, at the end of 15 years the cost of the steel-set will represent an investment of \$95.86, while the six wooden sets would stand on the books at \$153.56. The steel when replaced, at the regular market price for scrap will be worth \$12.03, while the value of the wood will be nil. On this basis the saving on the steel can be put down at \$69.73 per set, which means a saving per set per year of \$4.63. The tendency in the price of timber, however, is constantly upward, whereas the price of steel should remain fairly uniform, so that year by year the economy in the use of the steel should increase.

In the long run true economy is not so much a consideration of first cost as a question of life and durability. The large use of steel in American mines has been so recent that only problematical figures can be given for its durability. The assumption made above of a life of fifteen years is believed to be exceed-

ingly conservative, for the reason, in the first place, that steel mine-timbers exposed to temperature and moisture conditions have been in use in the Stearns shaft of the Susquehanna Coal Co. since 1897, and in the second place because English practice has given us records extending over a much longer period. The average life of steel-props in Warwickshire is said to vary from 10 to 13 years, as compared with three months for timber including in this estimate the time for re-setting the timber and its ultimate use for sprags and lids, so that by the use of steel-props a saving of one penny per ton of coal mined has been effected. The life of steel for props in all likelihood would be much shorter than the length of its service in square timber-sets, owing to the more severe handling the former experiences in removal and re-setting, so that it may be assumed as reasonable to expect steel square timber-sets to last as long as required in any one mine, however large the property may be, and however long it is necessary to maintain the gangway. This saving of 2c. per ton would mean, under present mining conditions, a reduction of timber-cost from 7.7 to 5.7c. per ton in the anthracite region, and is in itself an item for careful consideration. The life of the square timber-sets at the Maxwell colliery of the Lehigh & Wilkes-Barre Coal Co., above referred to, is considerably longer than the average in the anthracite region, where the workings are deep and the moisture-conditions deleterious to wood, and as a general rule it may be laid down that the longest possible calculation of the life of steel and the highest possible duration of wood, due to peeling, seasoning, and preservative treatment, steel is truly economical when its first cost can be kept down to three or four times the price of the timber it displaces.

By the substitution of steel for wood in this particular instance 4 in. of head-room was gained and 32 in. in width; that is to say, had the steel been used for wood in the first place, the excavation could have been made 4 in. lower and 32 in. narrower, which is quite a large item where the headings are driven partly or entirely through rock. In the installation at the Adrian mines of the Rochester & Pittsburg Coal & Iron Co., above referred to, the 4-in. beams took the place of 8-in. timbers, resulting in the saving of 4 in. of head-room, and as a general proposition this item is worthy of consideration in connection with the first cost of installation. The presence of decaying timbers in the mine is quite a large factor in the deterioration of the air and the consequent comfort and healthfulness of the operations, and is a large agent in the extension of deterioration to other timbers. It is plainly apparent that anything which will tend to improve atmospheric conditions will be steps in the direction of true economy, and such aid is to be found in the use of steel.

Inasmuch as all the timber for underground work has to be handled down the shafts or over the tracks, the reduction in weight to be handled effected by the use of steel is an item of large importance leading to cheapness in erection, and therefore to reduction in first cost of the installation. The wooden timber-sets for the Lehigh & Wilkes-Barre Coal Co.

required the handling in erection of 126 cu. ft. of wood, weighing approximately 6280 lb., whereas the steel weighed approximately 1690 lb. per set, without the base-plates; the saving in freight and cost of erection is apparent. With the steel there is no handling of excess material, as it is furnished by the manufacturers ready to assemble at the mines without waste. The wood, however, has to be framed, with a consequent loss in time and waste in material. A number of square timber-sets, at the Allport mines at Barnesboro, Pennsylvania, were handled by three men without difficulty, and erected in 15 minutes. No skilled labor is required, as in outside building work, the installation being conducted by the ordinary workmen. In this particular installation the sets weighed about 372 lb. each, complete, and were lagged in place by 2-in. plank. The ease of erection was so great, and the cost so small, as to be a surprise to the mine-owner. As a general proposition, the cost of erection of steel mine-timbers should not exceed 30% of the cost of wood of equivalent strength, allowance being made for waste and excess weight.

Another advantage of steel as compared with wood, of large importance, is its fireproof character, and if there were no other reasons for using steel in the mines, at least at pump-houses and at the foot of shafts, steel mine-timbers are to be recommended for commercial and humanitarian reasons, as its use in the situations exposed to fire will obviate to a large extent the destruction of life and property. Statistics of destructive fires in mines are not available, but at the Avondale shaft, Avondale, Pennsylvania, in the early sixties, occurred one of the disastrous mine accidents in the anthracite region which entailed the loss of the lives of about 100 persons, and which shut down operations for a considerable period. At one of the Shamokin mines within the past four years fire started in the dry timbers of the pump-house which resulted in the shutting down of the colliery for about four months with a loss to the coal company of the profit on 160,000 tons of coal. In the same vicinity, about the same time, a fire occurred which caused the loss of several lives, the shutting down of the mines for over two years, and the loss of profit to the mining and transportation companies on over 700,000 tons of coal. The use of steel, of course, will not prevent fires from gas explosions, but it has already demonstrated its usefulness in mines where explosions and fires have occurred, as, for example, at the Courrieres mines in France, and though it is possible to displace steel and to bend it so as to require re-straightening, it cannot catch fire. If stables, pump-houses, and the foot of slopes and shafts, were properly timbered in steel, the fire-risks in mining operations would be cut down to causes in a large measure not subject to human control. Another advantage in the use of steel as compared with wood which has especial reference to isolated props is the matter of re-use. Under present conditions the props are seldom withdrawn, and are usually utterly worthless when the time comes for their replacement. The timber in wooden gangway-supports likewise suffers from the same deterioration. Steel, however, will stand severe punish-

ment. As already narrated, in English mines roof-supports have been taken out, turned and used 200 times over, and the experience is fully corroborated by such use as has been made of steel in the United States. It is seldom that steel gangway-supports need to be removed, as they are usually put in permanent workings; at the same time the details are so simple as to offer no difficulties in the way of such removal and re-use, and even when the steel has served its purpose, and under heavy loads which taxed it beyond its strength, it has been so crippled and twisted as to be no longer safe for mine operations, it still possesses a relatively high value for sale as heavy melting-stock.

My experience in the use of steel mine-timbers has been confined to the anthracite and bituminous coal mines of Pennsylvania and Ohio. I have mentioned in passing an installation in the mines of the Copper Queen Consolidated Mining Co. at Bisbee, Arizona, where certain sections were put in a year ago. Recent reports from this seem to indicate that these sets, which were installed as an experiment, were found to be impracticable in swelling ground. A number of these were placed in only moderately heavy ground, and most of them are standing well. These are in drifts in which timbers rotted very quickly, and they used generally the 5 and the 4-in. H-sections which took a permanent-set after some length of time. Later the heavier sections were tried in a part of the mine which was extremely heavy, but which it was necessary to keep open, where 12 by 12-in. Oregon pine timbers crushed in about a month or less. At this point the Copper Queen used some sets of 6-in. H-section collars and posts, and a few other sets of 6-in. H-section collars and posts formed of 8-in. channels, pinned and bolted together. In this heavy ground they failed in about the same time as the timber, the posts bending out of shape and crippling badly. The double channel-legs were not so satisfactory as the H-section legs, and several H-section collars were crushed at the ends to about one-half the original height. This seems to indicate that the sets in question were too light for the service contemplated. As already noted, in the use of mine-timbers experience must be the guide in the absence of well-defined and accurate knowledge on which true engineering design may be based, and the comparative failure of the few sets under extraordinary conditions where results demonstrated that the sets in question were too light for the service, cannot be considered as an objection to the use of an article, the excellent character of which has been amply demonstrated in other situations.

In the iron mining districts there has been an ever-increasing use of steel for lining shafts, and excellent installations in which the new H-sections are used are to be found in the mines of the Newport Mining Co., together with large uses of steel of standard structural beams, angles, and rails, in the mines of the Oliver Iron Mining Co.

A company operating under the name of the Cia. Mexicana de Acero Productos Químicos, S. A., has entered into a contract with the Mexican Government for the manufacture of calcium carbide and other chemical products.

PARALYSIS OF MINING DISTRICTS.

By EDMUND B. KIRBY.

***The Mining Boom.**—The young man, who for the first time follows a mining rush to the point of some new discovery, sees an interesting and, to him, a strange phenomenon. Men by dozens, then hundreds, then thousands, are hurrying to the spot, followed by supplies of every kind. Ore is accumulating on dumps, or moving out on road or trail. Around the lucky discovery, as a centre, is a busy scene, the ever widening area of active claims, driving shafts and tunnels into the ground, searching for ore. Beyond them are the miles of claims staked by later comers. As each new point of discovery is announced, an outlying camp springs into existence. Buildings and towns appear as if by magic. At the focal point men swarm, and money pours in from every part of the country. Trading progresses night and day; the buying and selling of claims; the capitalization of hopes and chances into stock issues and the sale of these to an excited country which uses them as chips in the great game of the stock exchanges. Fortunes are made on every hand; a few out of ore, but the majority out of other people. The game is wild, boldly played, and with big stakes.

He comes a few years later, and the scene has changed to an industrial one. The few fortunate mines are digging, shipping, milling, and smelting. Their employees and the merchants who supply their wants are prosperous, but with pay-roll prosperity. All others have disappeared. The day of fortunes has gone. Around the industrial centre is a scene of desolation and waste. Digging there has ceased and the surrounding hills have become a cemetery. In every direction appear decaying head-frames and mine buildings, and the scars of innumerable excavations, each one marking the grave of some buried hope. The swarming town has shrunk to a factory village. In the outlying camps is the silence of industrial death. Then the years roll on, and as the discovered ore becomes exhausted, one by one the great mines stop, and the desert, calmly waiting, resumes its ancient sway.

And, after the man has seen other booms, and has learned of mining in other lands, and other times, he awakens at last to the fact that the life-process he has been noting is the same for every district, differing only in its length, or in details, which depend upon the country and the character of the discoveries. But, what is the reason for such a process? What is it that so quickly stops exploration? What is that strange paralysis which appears so promptly at the extremities of the district, and presses so steadily and resistlessly toward its centre? To such questions, the inquirer receives from mining men the ready answers: Perfectly natural! Necessary reaction! No ore! Dug out! Game over! Everybody gone home! But, suppose he has a brain which thinks, which is not put to sleep by ready-made answers, but wants to know: Why is paralysis natural? Why did the digging for ore stop so suddenly and

simultaneously, and why does it stay stopped? Was all the ore in this great area discovered in that brief spurt? Were those holes the intelligent work of experienced miners, or the reckless attempts of ignorant speculators? Is the camp really dug out? Why did everybody have to go home? Are such questions any more foolish than those of the men who first asked: Is smallpox natural? Is diphtheria necessary?

Land Withdrawn from Use.—Investigate the paralyzed area and on nearly every claim we find that the owner, whether an individual or a corporation, has practically finished all the digging he is ever going to do there. His money has run out, or the chances on that claim are too poor, in his judgment, to warrant the risk of more; or, he has never intended to do any more than the 10-ft. discovery hole and the pretense of annual assessment work necessary to hold the claim; awaiting the development of the country; improvement of transportation; methods of treatment. The vast majority throughout the West and Alaska are of the latter class. Not 1% of idle claim-owners seriously intend to dig, or make active efforts to raise money for that purpose. All are waiting. Much of the dead area is owned by defunct mining companies. Their stocks are scattered over the country; their officers have vanished and any attempt to do business with one of these concerns is a task the difficulties of which can be appreciated only by those who have tried it.

Examine the work done on each claim and we find that in the great majority referred to, the trifling discovery and assessment work has been merely perfunctory, and has furnished little or no evidence as to the mineral chances of the ground. These are still unknown; they are as good or as bad as they were before. In the cases where some real digging has been done, it is often found misplaced, or so unwisely executed that it has not settled the question at issue. Hence, most of the area tied up is still untested; still capable of discoveries, great and small. It still needs the work of the prospector and the miner, but has been permanently locked up beyond their reach.

Extent of the Paralysis.—Analyze all the varied plans and motives of these idle claim-owners, and we find that most of them are waiting either in the hope of profiting in some way by the work of other men, or with the expectation that in the distant future, investors will pay prices which they now decline. The dead-lock thus produced is the deadly paralysis which curses the mining industry today. There is nothing to break it; nothing to force action. There are no expenses. The assessment work of \$100 annually for unpatented claims, is usually faked, and the taxes are nothing, or so trifling as to be merely nominal. Owners can wait forever, and they do wait generation after generation, hoping that some time, in some way, the worn title deeds, or faded stock certificates, will enable them to extract a fortune from other men. And so, a great industry languishes, while paralysis, partial or complete, blights every district from the Mexican line to the frontiers of Alaska; prospectors have no where to go, and miners lack work, while investors and the rep-

*Address delivered before the American Mining Congress, Goldfield, Nevada.

representatives of mining capital are searching this and other countries for opportunities to mine.

That the mining industry can move at all under this handicap, is proof of its vitality. It is always struggling, ever breaking through the spell into new life here and there. Nature is prodigal, and the desire to mine is strong. Men still pay the price and take a chance. Some camps are so rich that development discoveries have slowly grown and extended for many years, bringing to life again, for important periods, large portions of the dead margin. In others, the great mines have lasted for generations. Sometimes new discoveries, or improvements in methods of mining and reduction, have brought dead tracts to life again. But, over the greater part of the vast mineral area, paralysis reigns supreme. The industrial life appearing and re-appearing here and there is, at best, only a mere indication of its latent possibilities; of what the mining industry might be if the disease which now represses it was eradicated. Dug out! Why, mining in this country has only just begun!

Difficulty of Compelling Operation.—Now, idle claim-owners, whether large or small, are doing only what any other men would do in their places. They are operating within the rules of the game. So are the *bacilli* of tuberculosis or of typhoid. But, the disease which such ownership produces in the industrial system has always been evident to the perceptions of all men. The common sense of miners has always declared that rights to mineral, like rights to water, should exist only with use. To hold them otherwise, is an injury to all. In the freest and finest expression of that common sense, the old District Mining Laws of the West, made and enforced by the working miners, two intentions always appear; first, to prevent monopoly and give everyone a chance; second, to force every claim-owner to dig or to get off so that others may dig. The principle of the latter requirement still appears in the present United States law in its provisions for annual assessment work, the continuous operation of tunnels, and the like.

The history of mining law shows that men have always maintained a difference between the right to mineral and that to other forms of land. It was clearly seen that mineral is valuable only when discovered and mined, and that it is injurious to the State to permit such private ownership as will hold it out of use. For centuries past, mining laws have been saying that no man has the right to hold mineral land idle; that he must dig, or allow others to dig. The application of this principle was effective in small frontier camps where the miners who made the law stood on the ground to enforce it, but as it passed into general law covering vast areas and became dependent upon the cumbersome machinery of government for enforcement, it was found impossible to compel the continuous operation desired. Some codes were more effective than others, but even the old Mexican law, the finest product of accumulated experience, was only partly successful in this matter. The reason for this strange fact is simple. It seems easy to frame a law which will order a man, under penalty, to dig continuously, but

as a matter of fact this is so difficult that it never has and never can be accomplished. How much digging, how shall it be measured, and by whom? In what place and at what rate? How about delays from misfortune, delays to supplies? What single rule will fit the poor prospector and also the rich corporation? Who is to stand over half a million claims and see that the work is done? At whose say shall a man lose his property? By the time all these points have been provided for, they have so weakened the law as to make it ineffective, and all that it is capable of doing is to retard, more or less, the progress of paralysis.

As another remedy, a penalty-tax upon idle claims has often been proposed, but when the attempt is made to define the difference between idle and working claims, all the difficulties aforesaid at once appear, and it is evident that this plan has no possibility of success.

The New Remedy.—But, the world is progressing not only in electricity and aeronautics, but also in other branches of knowledge, and a new light has been thrown upon the problem which has so baffled past generations. It has been discovered that the way to force the use of any natural resource is to tax it, not lightly in the ordinary way, but heavily enough to make it uncomfortably expensive to hold without using. The holder is then impelled either to let go, or to utilize it in some way. Here, at last, is a new way to solve this old problem, a way to accomplish perfectly what the mining world has always been wanting and trying to do. It is the way to end promptly and forever the paralysis of mining districts. The old method was to give men orders which could not be enforced. The new method gives no orders. It lets every man do as he wills, but it applies to each man a new and subtle force, continuous, persistent, unevadable, the force of his own pocket, making him now want to dig, or get off the claim.

But the question may be raised; how can it help an industry to tax it? The answer is that the industry, the digging out of the mineral, is not taxed. Every man is made to pay for occupancy; for holding a reservation of mineral ground away from other people who want it. Such a payment, when made just large enough to be uncomfortable, or painful, on an idle claim, would be only a small item in the expense list of an operating claim, for it takes money to mine. Such an item would never stop, or discourage digging. In producing mines, it would be far less than the royalties now paid everywhere by miners to idle claim-owners. When a man has to pay for the privilege, he will not hold more ground than he intends to work. When the privilege of holding is free, he will naturally grab everything in sight and wait in order to hold up some one else who may want to use it. Let the dog in the manger pay for his manger.

Strange as it may seem at first sight, the way to boom an industry is to tax the natural resources it uses. The way to discourage it, is to tax anything else it uses, or to tax its products. This scientific principle of modern taxation is now as firmly established as any law of chemistry or physics, and is

slowly but steadily, forcing its way into the tax-systems of civilized countries. If you want to encourage the utilization of water-power, tax water-falls so heavily that no one can hold one idle, or away from would-be users, and only actual users can pay the tax. To discourage use, tax the buildings, machinery, supplies, or income. The best and the scientific method of applying the tax to claims would be by assessment according to their actual values. But any method will work, so long as it is carried far enough to produce the effect. It will, of course, be necessary to prevent tax-dodging. Any State, or any county, may apply the remedy at will, for even if there are limits to the tax-levy it may impose, there are none to its powers of assessment. It can apply the pressure and steadily increase it, watching the effect, until this has reached the point desired.

As a starter, which will serve to give partial relief promptly and generally, a certain improvement may be made in the United States assessment law. This is to change the present requirement of \$100 worth of assessment work per year on unpatented claims, into a cash payment of \$100. The object of this change would be to make a weak law more effective by converting it into a taxation scheme. At present, it is better than nothing, but still a failure, for the simple reason that there is no way to stand over hundreds of thousands of claim-owners and see that each one does his work, and that it is really worth \$100, and so this provision is evaded in various ways. The payment of \$100 in cash, however, would be clear and definite, and much harder to evade. Dodging may be prevented entirely by suitable provision in the law. This amount, acting as a tax, and made non-evadable, would set free for the prospector at least one-third of the claims now held in the United States and Alaska. The remaining work would have to be done by State and county taxation, and by Congress for Alaska. The present assessment law is all that is left of past efforts to make men dig or get off the claim, and it should not be altered, except for the deliberate purpose as aforesaid of converting it into a more effective instrument. It may be added that an incidental advantage of the improvement suggested is that the record of payments made will do away with many of the present title uncertainties now due to pretended assessment work.

Relief to Prospectors.—It will be argued that a tax of \$100, to say nothing of additional State and county taxes, would ruin the prospector. As a matter of fact, it will have exactly the opposite effect and nothing can be more to his benefit than measures which tend to check monopoly and force every one to dig, or get off the claim. Suppose he has to let go of his single claim? What has he made out of it? It has never yielded him anything but dreams. Are not hundreds of thousands of claims, just as good or better, now thrown open to him to prospect, or to hold when he pleases? It is simple arithmetic. Lose one and gain a hundred thousand, which is the better? Will not the surface of the earth once more be open to him to prospect as in the old days? Today it is shut off, staked and monumented as far as the

eye can see. He is like the Indian and the cow-puncher. His business is gone. The wonderful judgment and skill in finding ore deposits, gained by years of experience, are now useless. A few young and less experienced men may reach the unstaked frontier in Alaska, but he cannot. He asks despairingly, Where can I go? What can I do? So, he settles down upon some fourth-class chance, which the crowd of claim-stakers have passed by, or abandoned, and hangs grimly on to his last hope.

Let us look squarely at the facts. A very small percentage of the idle mineral claims are owned by prospectors. The overwhelming bulk is held by mining companies, or by individual investors, who have shut off the prospector and destroyed his business. In most cases, the few claims he is supposed to own, are, in reality, only part his. The investors who furnish his grub, own from a half to a three-quarter interest and the tax-money would, like other expenses, come from them. The prospector is virtually only their watchman or care-taker. The fact is that the prospector himself is not a success at the game of idle claims, and rarely makes it pay. His real business is not claim staking, or watching stakes, but the discovery of ore-deposits. Give him back his regular business, and his chances of making a fortune will be multiplied a hundred fold. The prospector does not have to be mollycoddled. He can stand any laws which are necessary for his own and the general good, and can raise tax-money, when wanted, in the same way that he now raises his expense money. Mining investors are always eager for opportunities and every prospector who makes a real discovery, worth holding, is promptly beset by men who crowd their money upon him. If the claim is not valuable enough to interest others, he will not hold it, and so will pay no tax. If it is desired to force large companies with areas of two, four, ten square miles of valuable mineral land to dig or get off the claim, the prospector must do likewise. A far more profitable business awaits him, and with the flood of prosperity which will follow more digging and free mineral land, he will never want a job or a grub stake, or financial backers and purchasers for his discoveries. Abolish the claim-staker and give the real prospector a chance once more, and you will hear of new discoveries from every quarter. Dig or get off the claim!

The question may present itself whether a tax of \$100 per claim, while applying the necessary pressure to ordinary claim-holders, will not be too small to be felt by mining companies. This would be true in many cases, but this tax is only suggested as a convenient and universal starter. The further pressure needed in such cases must be applied by State and county taxation. As a matter of fact, however, nothing is more sensitive than the pocket of a corporation, particularly if that corporation be idle, or the pocket empty. Even the tax of \$100 will have a wonderful effect in causing mining companies to trim their edges, and further pressure may be made to squeeze their holdings down to actual working needs.

Investors Attracted.—Another question which will be raised is whether the taxation of mining claims

would not interfere with property rights; destroy the value of investments; scare away investors. What rights? The right to hold a claim without using it? Don't you want to discourage that? Has not the mining world for centuries forbidden it and tried in every way it knew to prevent it? Investments in what? In idleness? In a hold-up of industry? Don't you want to destroy the value of such investments? Scare what investors? Those who want to dig; to do real mining; to build mills; smelters; railways; towns? On the contrary you will draw them in swarms, because when holders have to dig or get off the claim all who have claims worth mining, will make their offers for working capital attractive enough to get it.

What first excites and draws investors into mining ventures is the chance to find ore by actual digging. This is what they ask for. It is the chance of discovery, and not the acreage of a property which brings their money. At first they are not, as a rule, interested in the other game of waiting to hold up some future producer, and, in fact, do not even think of this, unless fortune turns against them and work comes to a stand-still. Then they naturally want all the chances for salvage that the rules permit, and paralysis ensues. Is it not right to say to these men: you have had a miner's chance, sorry your money is lost, but it is gone and there is no reason why you should take it out of some other man's pocket; these claims are worthless until ore is discovered and mined; the State wants this done, and will not let you paralyze its mining industry; if you are through digging, get off, so that some one else may dig? That is what the common sense of miners has always said. It is what the mining laws of the world have always said, but with a feeble voice. Is it not time to say it now with a loud voice and make it go? Dig, or get off the claim!

Advantages to Claim-holders.—Even idle holders themselves see that they have brought on a dead-lock which is not to their own advantage. Very few really make any money at it. Men grow old and sink into the grave, still dreaming of the purchaser who never comes. In the great majority of cases, all that holders will really lose by the proposed change in the rules, are their visions, their hallucinations. In exchange for these, there will be the countless opportunities of a rejuvenated industry. Is it not as clear as day that by the pressure of increasing taxation, every claim may be forced into use, or released? When from Mexico to Alaska every claim is either working, or open to prospectors, does it take a prophet to see the result? Does not every prospector know of areas he would like to explore? Does not every miner, every operator, know of places where he would like to dig? After the real mining industry begins, cannot every one foresee in its general, steady and permanent prosperity, a better living and more chances for a fortune than are possible under the present paralysis?

Men of the mining world, the new era awaits your call. You have but to say the magic words, Dig, or get off the claim!

Traction is directly proportional to the load, and inversely proportional to the diameter of the wheel.

DEFLECTING ANGLES WITH A 30-FT. TAPE.

Written for the MINING AND SCIENTIFIC PRESS
By LEE FRASER.

A 30-ft. length of tape is a convenient device for the measurement of deflection angles, when no greater accuracy is required than within 0°30' to 1°0'. Presuming that the slight amplification to the tape has been made, as indicated in the figure, reference to the accompanying table will disclose the proper distance to be taken on the tape for deflection angles from 0° to 90°. The operation of deflecting an angle consists in first stretching the 10-ft. base on the line from which the angle is to be turned, and securing it by pins as indicated. The remaining 20-ft. length of loose tape is now taken, at a distance from zero corresponding to the distance in feet in the table, opposite the angle it is desired to deflect, and upon stretching the tape, holding at the distance corresponding to the angle in the table, the required deflection is made. The values in the accompanying table were calculated from the equation of the ellipse for every five degrees, interpellations being made two times for the intermediate degrees. It was not found practicable to continue the computations for deflection-angles of greater magnitude than 90° on

CYANIDING CONCENTRATE AT TARACOL, KOREA.

Written for the MINING AND SCIENTIFIC PRESS
By J. D. HUBBARD.

The old percolation process is regarded as a bit out of date at the present time, but there are still odd corners in the mining field where conditions make it necessary. Here in Korea it has been found profitable, although far from the high metallurgical standard of modern practice. The 'modus operandi' obtaining at the cyanide plant of the Oneutar Consolidated Mining Co., at Taracol, Korea, might be of interest to the metallurgical profession.

The concentrate treated consists of marcasite, 56%, galena, 36, sphalerite, 6, and arsenopyrite, 2. These percentages vary on different levels in the mines, but do not affect the extraction of the precious metals contained, as all these minerals (with the possible exception of arsenopyrite) offer no great obstacle to successful cyaniding.

Sizing tests on this concentrate also vary from time to time, and these materially affect the extractions. Two sets of sizing-tests showing about the limits each way, are as follows, the results being the average of several tests:

| No. 1. | | |
|------------|-------|-----------|
| Screen. | | Per cent. |
| On 50 | | 16.4 |
| On 80 | | 18.2 |
| On 100 | | 12.0 |
| On 150 | | 18.0 |
| On 200 | | 3.4 |
| Passed 200 | | 31.9 |

| No. 2. | | |
|------------|-------|-----------|
| Screen. | | Per cent. |
| On 50 | | 23.4 |
| On 80 | | 20.1 |
| On 100 | | 19.3 |
| On 150 | | 19.1 |
| On 200 | | 4.1 |
| Passed 200 | | 13.4 |

In treating a product like No. 1 an actual extraction of 86% of the total head is obtained, and on No. 2, 80%. All the product passing a 100-mesh screen gives a high extraction by percolation (over 90%), but this would not be possible if the fine product were treated by itself, as it would pack heavily. It is necessary to have a certain amount of coarse material to afford a proper leaching medium. This coarse product, that is, all material that is caught on a 100-mesh screen, contains most of the remaining gold after leaching, and this is the main defect of the percolation process for cyaniding concentrate. It will be necessary to re-grind this coarser product to obtain a better extraction, and the company is planning to this end. A tube-mill and agitation plant is to supersede the percolation plant.

The present plant consists of 18 circular percolation vats, 22 ft. diam. and 6 ft. deep, of riveted sheet-iron. A grating of wood is fitted into each tank, 10 in. from the bottom. This allows the necessary space for air and solution. On this grating a burlap filter-cloth is placed, and carefully wedged down

around the edges. On top of this burlap filter, Korean rice-straw mats are placed, to protect the burlap from the points of the shovels. Sixteen mats are used to cover each filter-bottom, and cost 22½c. each. They last one year, and the burlap filter-cloths from three to five years. These rice-straw mats are unaffected by strong cyanide solutions, and only have to be changed when the mesh becomes filled and cemented with fine concentrate. Aeration prolongs the life of both filter-cloths and mats, by forcing the fine concentrate up and out of the mesh.

Four settling tanks, each eight feet square and four feet deep, receive the gold-bearing solution from the percolation vats. One tank is used for wash-water, one for weak solution, and two for strong solution. Proper piping connects the percolation vats with the settling tanks. Aeration is carried on through the same pipes, by using an extra valve on each pipe from the main air-pump line.

Eight zinc precipitation-boxes, 14 ft. 10 in. long by 2 ft. 15¼ in. wide, are used for the precipitation of the gold and silver from the solutions. There are eight compartments in each box, each compartment 18 by 34 by 24 in. deep, and containing 9 cu. ft. of zinc shaving. One box is used for weak, one for wash-water, and six for strong solutions. There are three circular, riveted sheet-iron sump-tanks, 25 ft. diam. and 10 ft. deep. One is used for strong solution, one for weak, and one for wash-water. Duplicate 4-in. centrifugal pumps handle the solutions with ease and economy. One pump is held in reserve in case of accident to the other. A Hampton zinc-lathe with 36-in. mandril, cuts the necessary zinc shavings. From 1800 to 2600 lb. of zinc shaving is used per month. Vacuum and air-pumps, filter-boxes, a small crusher for slags and fluxes, also melting and roasting furnaces, complete the equipment. There is a well-stocked laboratory for testing and chemical analysis.

The fresh concentrate from the mills is trammed by gravity in one-ton cars to the cyanide plant, weighed on platform scales, and net weight of wet concentrate recorded in the scale-book. Two samples are taken from each car, one for assay and one for moisture. Care is taken that the sample-rod be driven to the bottom of the car, to insure a good sample. The day's run of fresh concentrate is then dumped into the vat ready for it. A few cars of coarse sand from the 'spitz' boxes in the mill, are mixed in with the concentrate in the charge, at the discretion of the operator. The concentrate is drawn off the vanners in the mills with from 30 to 50% sand. This mixture has been found to be necessary in practice, to secure a good percolating medium, and a better extraction. Without the sand, the charge 'packs' in the vats, and a poor extraction results. Lime is also mixed with the charge at the rate of 2½ lb. per ton. This gives us a protective alkalinity of between 0.50 and 0.60% (in terms of N/10 oxalic acid), which is just right for the solution. A lower protective alkalinity causes a higher consumption of cyanogen, and a higher one causes a crust to form in the sump and main pipes of lime and iron carbonate. This caused considerable annoyance and loss of time, with the protective alkalinity.

ity at 0.70%, as the pipes had to be disconnected and the crust cleaned out. This question of protective alkalinity has been experimented on and discussed by many prominent metallurgists, with varying results. Some claim a regeneration of cyanogen by carrying a high protective alkalinity; the regeneration obtaining from the double cyanide of zinc, the alkali decomposing the same, forming zinc hydrate and liberating cyanogen. This is not the case here. After a series of careful tests, covering several months, on working and sump-solutions, I found that excessive protective alkalinity did not regenerate cyanogen in the working solutions, and but slowly in the sump-solution. Tests on a sump-solution allowed to remain quiet, showed a slight regeneration of cyanogen from day to day, until, at the end of two weeks it remained stationary. The solution on entering the sump tested as follows, these results being the average of several tests: total cyanides, 0.48%, free cyanide, 0.23%, protective alkalinity, 0.76%. After one week the free cyanide increased to 0.26%, and after two weeks to 0.28%, where it remained. Tests on the main working solution, constantly in circulation, did not show regeneration, and as the pipes caked so rapidly as to become ineffective in four days to one week's time, I was obliged to drop the protective alkalinity to a normal point, which was found to be 0.55%. A few hundredths either way did not cause any inconvenience or loss. I hope to take this matter up more fully in a future article.

After the leaching vat is charged to its proper capacity, a wash of clean water is run on and allowed to percolate for 24 hr. This water is heated in winter. The water-wash carries out all soluble sulphides and acts on the lime which removes all traces of acidity, and leaves the charge alkaline, and in a receptive condition for the cyanide solution. This wash is run directly to waste, as it is very low in value, 0.02c. being the average per ton of solution. This small value is taken mainly from the pipes in passing through.

In the past, a preliminary weak-solution was run on the new charge, and allowed to flow through the weak zinc precipitation-box. It caused all kinds of trouble, a large quantity of the soluble matter settling in the head-compartments of the weak-precipitation box, necessitating the cleaning up of the same every other day. It also gave from 200 to 350 lb. of practically valueless matter in the precipitate, which had to be melted down with the rest on the clean-up. The preliminary water-wash does away with this trouble.

After 24 hr. washing, a strong cyanide solution is run on the charge (0.48% double cyanide, or $2\frac{1}{2}$ lb. KCy per ton of concentrate); and allowed to percolate for 16 days. Then a weak wash for 12 hr., and a water-wash for 12 hr., thence to the dump. The charges drain down to 18% moisture before going to the dump. Each charge is changed twice during its cycle of treatment (18 days), by shoveling over from one tank to the other. This labor is done by the Korean coolies, 12 on each shift. The 18 percolation vats in use are divided into six series of three vats each. This allows two complete changes or turning over of the charge. One vat is discharged to the

dump each day, and one vat filled. At present the mill is treating 2100 tons of fresh concentrate per month, or 70 tons to each charge.

Aeration is carried on intermittently, two vats at a time, for a period of one hour each. A two-cylinder, clack-valve, plunger-pump, made in the company's Taracol shops is used. It only consumes $3\frac{1}{2}$ hp., and requires little attention beyond oiling. Constant aeration is an important factor. Without it the total extraction not only falls off alarmingly, but necessitates a frequent renewal of working solutions.

The gold-bearing solutions from the percolation vats are run to settling tanks, and from there to the zinc precipitation boxes. The rate of flow for each box is $10\frac{1}{2}$ gal. per minute. The total extraction is excellent, the head varying from \$1.40 to \$3 per ton of solution, and the tailing from a trace to 0.06c. per ton. From the precipitation boxes the solutions are run to the sumps, where they are strengthened by the addition of the necessary KCy, and from there pumped back onto the charges. Clean-ups take place twice a month. The first clean-up is only a partial one, three or four of the head-compartments in each of the strong-solution boxes being cleaned. An accumulation of precipitate in these head-compartments, below the screen, prevents the free circulation of solution, necessitating a clean-up. The precipitate is run to a filter-press, where the solution is separated from the slime or precipitate by a vacuum-filter. When dry, the slime is removed to the strong-box to await the final clean-up at the end of the month. On the 30th of each month the regular clean-up is started. The strong-solution boxes, launders, filter-boxes, precipitate box, and others are unlocked and made ready. The clear solution from the zinc-box compartments is siphoned off carefully and goes to the sump. The zinc is then removed and well scrubbed by the Korean boys. These Koreans are not as thick-skinned and immune to cyanide sores on the hands and arms as the Kaffirs, so each boy greases his arm to the elbow with vaseline. The slime is tapped off through the lower plug in each compartment, and run to the filter-box, and the vacuum-pump started. The compartment is then washed thoroughly, the plug and screen replaced, and the washed zinc put back. The short-zinc goes to the head-compartment in each box, and is all consumed by the following clean-up. Fresh zinc is placed in the compartments not filled by the old zinc. The practice here is to let the zinc run down pretty low in the compartments by the clean-up, thus giving less bulk to handle. Care is taken of course that the solutions do not 'channel' or make holes in the zinc, and it is found that the precipitation is just as good. Care is taken not to stir up or disturb the zinc shavings in the compartments during the month, but to add fresh shavings on top of the old, very carefully, when needed. Every time the zinc shavings are agitated or stirred (to loosen the slime), a considerable loss occurs; much fine precipitate is carried over to the sump, where it is lost. As the precipitated gold is then in an allotropic form, it is not re-dissolved in cyanide solution, and consequently, when the sump solution is pumped back for leaching, the precipitate is caught in the charge and lost.

An operator, in describing this slopping around of the zinc-shaving to shake the precipitate off, will say, "after allowing the slime to settle," the "solution is turned on." But if any operator can make this same slime 'settle' naturally, and a portion not rise and overflow the instant the solutions are turned on (I do not care if he settle them a full month), I will confess I had something to learn on that point. This class of practice parallels the decadent mill-man, who has his secret 'dope' to put in his batteries, thereby saving more gold from the ore than Nature originally put there. When the compartments get 'dead' or in bad shape, they are cleaned but never stirred up. After the boxes are all cleaned and the slime collected in the filter, and vacuum-filtered dry, it is removed to the precipitate box, preparatory to roasting.

About 100 lb. of the slime is charged into the roasting pan, and spread out evenly. The furnace is then fired with wood. The slime is not disturbed until the pan-liner shows red through the cracks in the charge, and then the lumps are carefully broken with a hoe made for that purpose. This causes a minimum of 'dusting'. Continual stirring and breaking up of a charge in the pan always causes a maximum of 'dusting'. There is a hood over the pan, and dust chamber 6 by 3 ft. 18 in. of riveted sheet-iron, and using the greatest possible care in roasting, there was still obtained in the past year a little less than \$500 from the dust chamber. When the roast is 'sweet', or will not show any sparks on stirring, it is carefully removed from the roasting pan to a fluxing pan, and then taken to the scales. The fluxing charge consists of 45% borax, 30 old slags (preferably from the assay office), and 25 coarse sand, and is mixed with the roasted precipitate while hot. This also avoids loss by 'dusting'. The coarse sand contains a quantity of pyrite, and this materially assists in the formation of the matte on the gold button. This matte is a benefit, as it keeps the slag values down. One month clean sand, free of pyrite, was tried, and scarcely any matte was formed, the slag running up in value.

A former operator here informed us that the iron to supply the "matte forming element" was derived from "scales from the roasting pan", but this is not so. No iron scales are obtained until roasting the last charge is finished, and these scales are picked out and thrown with the slag, as they contain trifling amounts of gold. They will not even melt in the crucibles, but hold back when the gold button is poured.

The melting furnace consists of three circular pits, 30 in. deep and 22 diam. These pits are on three sides of the stack, and the roasting furnace is on the fourth side. Charcoal is used for fuel, as it is the most readily obtainable. The price of either coke or oil is prohibitive. No. 80 black-lead crucibles are used, as they have proved to be the most economical size for this size of furnace. These crucibles are charged three times for each melt, and then poured into a conical mold. When cool the top slag is knocked off, and the gold button with the matte-capping put in the safe.

American or English crucibles are good for from

14 to 20 melts, while the Japanese crucibles are only good for 7 to 11 melts, although cheaper in price. The American or English crucibles have proved to be the most economical in the long run here. After the month's run of slime is all melted down into buttons, the matte is separated from the gold, and put through the crusher. It is then charged into the crucible with alternate layers of borax, matte, cyanide, and sand, and given two full heats in the furnace to 'cook' it thoroughly. The sand retards the reducing action on the crucibles, thereby prolonging their use. The resultant button is high in silver, and contains a small amount of gold. An average bullion-assay on the matte-bars gave, gold fineness 42.96, silver fineness 269.51, and base 687.53. Sometimes the silver will run up to 600, but the gold remains the same. The gold buttons are run into bars. The slags from the clean-up, assay from 22 to 60c. per pound, and are treated in a special blast-furnace.

There are two other cyanide plants on the concession, one at Candlestick, and one at Kuk San Dong. The Candlestick plant is shut down at present, as the mine was behind in development. When it starts again there will be some radical changes, as the agitation process did not prove altogether a success. The chief troubles were the high cost of treatment, and the errors made in the mechanical construction. In practice it was found that the agitation plant was only able to handle the pulp from five stamps, instead of ten. The extraction was good.

The Kuk San Dong cyanide plant is operating on a low-grade concentrate with satisfactory results. Practically the same conditions obtain there as at Taracol, and the same process is used. It is intended shortly to install tube-mills for re-grinding the concentrate, and change the plant, to secure the highest economical extraction of the gold and silver in the pulp.

ASPHALT PRODUCTION.

According to the United States Geological Survey, the output of natural asphalt, related bitumens, and bituminous rock that entered the market from quarries and mines in the United States in 1908, together with refined asphalt produced from the crude material, was 185,382 short tons, valued at \$1,888,881, as compared with 223,861 tons, valued at \$2,826,489, in 1907. The largest item in the 1908 output was oil asphalt, which amounted to 102,281 tons, valued at \$1,322; this also showed a decrease from the 1907 output. Bituminous rock (37,371 tons, valued at \$146,821), gilsonite (81,533 tons, valued at \$61,824), and maltha (12,875 tons, valued at \$162,000), were next in order of importance. The imports of asphalt in 1908, mainly from the island of Trinidad, but in part from Bermudez (Venezuela), Cuba, Germany, Italy, Mexico, and a few other countries, were 151,674 tons, valued at \$624,979. During the fiscal year ending June 30, 1908, domestic asphalt and manufactured asphaltic material to the value of \$451,968 were exported from the United States, an increase of about 20% over the exports in 1907.

The output of gilsonite exceeded 10,000 tons. This asphaltic mineral came exclusively from Utah, where it occurs in veins of great size.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Magnesite was imported into the United States in 1908 to the extent of 84,494 tons, having a market value of \$736,763, or \$8.72 per ton.

Foliated is proposed by E. S. Bastin as a convenient comprehensive term to include all rocks showing foliated structures other than bedding planes. Its use avoids frequent repetition of the two terms schists and gneisses and avoids any postulate as to the primary or secondary character of the foliated structure.

Graphite is concentrated by log-washers and bud-dles. The product is then dried and subjected to further cleaning by air-jigs. Re-grinding is also practiced, the tube-mill commonly being employed for that purpose. The finely ground graphite is then refined by pneumatic separation in machines specially designed for that purpose.

Tantalum is used chiefly in the manufacture of incandescent electric lamps. Such lamps are said to consume fewer watts per candle-power, and to produce a light of exceptional whiteness and brilliancy. Also they will stand sudden increases of current without burning out. A tantalum lamp will last from 400 to 600 hours, requiring from 1.7 to 2.1 watts per candle-power.

Trinidad asphalt is well known. The surface of the famous pitch lake is about 138 ft. above the sea; its area is 100 acres, and borings have shown that it fills a bowl-like depression with steep sides and a depth of more than 135 ft. This lake has been estimated to have a minimum available content of over 9,000,000 tons. More than 2,000,000 tons have been removed and exported since records have been kept. The exports in the year ending January 31, 1909, were 150,557 tons, of which 98,098 tons came to the United States.

Map models may be conveniently made by marking on separate glass plates the working for each level. The individual plates should then be placed one above the other in a rack, the vertical distance between plates being proportional to the distances in the mine between levels. While the workings may be painted on the glass. A quicker and more convenient way is to use strips of adhesive tape such as is sold by stationers for passe-partout work. This tape can be obtained in various colors, but will usually need to be trimmed to make it conform to the scale of the model.

Carbon or so-called safety inks are used for drawings, drafting and the drawing of monetary instruments. They are always thick, stringy and are unsuitable for a free flowing writing fluid where anything else can be used. They, as a rule, are made by triturating lampblack with gum arabic and oxalic acid, and are thinned with water. Ink so made, while resisting acids and the alkalis, will oftentimes yield to the washing with pure water, as they do not

penetrate the paper to any extent. Skillful manipulation of the acids and alkalis separately or together will remove them. The only safety in their use is in connection with sensitive or safety paper.

Ammonia is a solvent for the native carbonates of copper, malachite and azurite, as well as for both cupric and cuprous oxides. Ammonium carbonate also dissolves these salts. Concentrated ammonia is not necessary for this purpose. The only drawback is the cost of ammonia. If a large demand were made in the vicinity of coalfields it could be cheaply obtained as a by-product in retort coking; but copper ores are usually nearer available supplies of cheap by-product sulphuric acid, which is practically better for leaching and subsequent precipitation. We are not aware of ammonia-leaching being practised on a working scale in the United States.

Tellurides of gold and silver are capable of completely precipitating gold from its solutions. This was shown by experiments made by Lenher and Hall on gold-chloride solutions. The association of free gold with tellurides is due in part to reconcentration from gold carried down in veins by descending waters, the tellurides serving as the precipitating agent. Also free gold is thrown down in the same way from ascending solutions. This is thought to have occurred in the Kalgoorlie district, in western Australia. The tellurides are almost universally associated with gold ores, accompanied with iron pyrite and other sulphides. It is generally conceded that the presence of tellurides indicates a deep-seated origin of the gold-bearing solutions.

Mineral paints may be divided into three groups—(1) natural products such as ochre, umber, sienna, hematite, siderite, limonite, ground slate and shale, which after mechanical treatment, such as cleaning and grinding, are either used directly as pigments or are first roasted to give certain desired colors; (2) chemical products, such as zinc oxide, leaded zinc oxide, zinc-lead, sublimed white lead, and sublimed blue lead, which are made directly from ores of valuable metals; and (3) chemical products such as basic carbonate white lead, litharge, red lead, orange mineral, lithopone, and Venetian red, which pass through several metallurgical and chemical processes in their preparation from the original ores.

Costs of open-cut mining vary with conditions. At the Boston Consolidated, in Utah, the following figures are given:

| | |
|--------------------------------|----------|
| Supervision | \$0.0034 |
| Operation, well drills | 0.0134 |
| Operation, air drills | 0.0066 |
| Blasting | 0.0308 |
| Operation, steam shovels | 0.0588 |
| Operation, railroad | 0.0435 |
| Dumps | 0.0147 |
| Operation, tram and ore-bins.. | 0.0020 |
| Shop, tools and machinery.... | 0.0078 |
| Maintenance of buildings | 0.0002 |
| Miscellaneous | 0.0013 |

Total, per ton.....\$0.1825

PRE-CAMBRIAN GEOLOGY OF NORTH AMERICA. By C. R. Van Hise and C. K. Leith. U. S. Geol. Survey, Bull. 360. Pp. 939, 2 col. maps. Washington, 1909.

This report is a revision of the Correlation Essay published in 1892, and a compendium of pre-Cambrian geology, with a general account of the pre-Cambrian rocks, followed by summaries by districts.

Catalogues Received.

THE CYCLONE DRILL CO., Oroville, Ohio. Bulletin No. 3. Mounted Core Drills. Illustrated, 44 pages, 6 by 9 inches.

INGERSOLL-RAND CO., 11 Broadway, New York. Bulletin 4004, 'Arc Valve Tappet Rock Drills'. Illustrated, 12 pages, 6 by 9 inches.

ERNST WIENER CO., 50 Church street, New York. Catalogue No. 200. Industrial Cars and Track Material. Illustrated, 130 pages, 6 by 9 inches.

D. D. DEMAREST CO., 503 Market street, San Francisco. Circular 27. 'Pacific Stamp Stem Guides'. Descriptive of an all-metal renewable guide of stamp stems. Illustrated, 8 pages, 7 by 10 inches.

THE HAYWARD CO., 50 Church street, New York. Catalogue No. 36. Digging Machinery. Contains a great many excellent views of engineering work where Hayward buckets have been used. A terse explanation accompanies each picture and makes the book of great value. Illustrated, 111 pages, 9x6 inches.

Wire-Rope Sockets.

All wire-rope users will want a copy of a little booklet just issued by the John A. Roebling's Sons Co., Trenton,

New Jersey, entitled 'Wire Rope Sockets'. It contains a minute description of the right way to attach sockets to wire-rope. The instructions are made clear and more interesting by the use of a number of admirable illustrations, one of which is reproduced herewith. It is certain that fewer accidents, due to failures of cables, would occur if all

connections were made in accordance with this method. Included in the booklet are illustrations of numerous wire-rope fastenings and hooks.

New Inverted-Type Assay Balance.

Recently in America there has been a revival of the inverted-type of assay balance, one of the earliest designs of European makers of precision balances, although now given an inferior position abroad, due largely to the more energetic development of the familiar form with dependent pointer or indicator. The accompanying illustration shows a new model just put out by a leading maker, and having numerous improvements over existing types.

The beam is of truss design, made of hard rolled magnesium, an alloy equal in strength and of about one third the weight of the brass or bronze commonly used, effecting thereby a reduction in the inertia of the moving parts with a consequent increase in speed and sensibility. The rider-carriers have no metal-to-metal surfaces in sliding contact, hence are smooth in operation under adverse working con-

ditions. The graduations are in hundredths, on a celluloid index, each division representing 1/100 of the weight of the rider used. The end-bearings are of one solid piece of agate, supported by agate contact-points when at rest, and the releasing mechanism is of improved design, thereby eliminating the disadvantages of earlier balances of this type, operating absolutely without 'kick'.

The unite-base carries the entire mechanism above the glass base, and maintains perfect alignment under all conditions, and having less than one half the parts of other balances of this type, its simplicity and the ease with which all parts may be removed for cleaning and replaced without disturbing their adjustment will appeal to users, at a distance from the factory. This balance is made by William Ainsworth & Sons, makers of balances and engineering instruments of precision, Denver, Colorado, and is fully described in Bulletin A-9.

ACCORDING to an advance chapter of 'Mineral Resources of the United States, Calendar Year 1908', just published by the Geological Survey, the production of natural mineral paints in 1908 showed little change from that of 1907, increasing by only 1307 tons, or \$6056. The 1908 output was 49,853 tons, valued at \$536,544. The production of pigments made directly from ores was 75,133 tons, valued at \$6,946,283, as compared with 95,211 tons, valued at \$8,939,332, in 1907. The output of chemically manufactured pigments amounted to 182,364 tons, valued at \$20,708,940, as compared with 186,677 tons, valued at \$23,119,692, in 1907.

L. VOGELSTEIN & Co. give the following figures of German consumption of foreign copper for the months January to July 1909:

| | Tons. |
|----------------------------|--------|
| Imports of copper..... | 94,681 |
| Exports of copper..... | 4,512 |
| Consumption of copper..... | 90,169 |

as compared with consumption during the same period in 1908 of 89,819 tons. Of this quantity 86,813 tons were imported from the United States.

Uses and Limitations of Electrolytic Amalgamation.

By J. H. JORY.

Brief outlines have been given of the methods of electrolytic amalgamation, in regard to the forces employed, the manner in which these are controlled, and the results obtained in practice. It may be again said that the system comprises mechanical, chemical, and electrical processes, so combined as to produce, almost instantly, a powerful amalgamating force on all precious metallic particles present in pulverized ores, as they flow through the apparatus in a stream of water.

Under this force all such particles are carried to the lower plate, which serves as the cathode, where they become amalgamated and adhere; uninfluenced by the scouring action of the flowing sands. The results obtained are a very perfect recovery of gold and platinum from all kinds of sands or ores, no matter how coated these precious metals may be, or in however finely divided a condition they may be found, depositing metals in suspension as readily as those in solution. It performs this work in the

Jory Electrolytic Amalgamator.

one operation, without re-handling of the ores; there is no loss of time in concentrating, leaching, or filtering; and the expense is as low as one fifth of that in other operations, approaching this in efficiency. This system of recovery applies to every form of gold-bearing sand, and may be used by the hydraulic miner, or the gold dredger.

The system may also be used by the quartz-miner in the extraction of gold, whether these ores contain sulphides or not.

In the cut, illustrating this article, is shown a carefully constructed sluice employed in electrolytic amalgamation. This is now being used in the laboratory of the Noble Metals Recovery Co., in San Francisco, for testing purposes. It has a capacity of six tons of ore per 24 hours, and is the smallest size designed for practical work. It may be used for prospecting either on quartz, or in placer claims. A larger apparatus capable of treating 100 tons is the standard size, as now contemplated.

For hydraulic mines it will take the place of the under-

current. On the dredge several of these sluices may be used to take the place of the apparatus now relied on. In the stamp-mill it simply takes the place of the well-known plates, and is designed to produce results rendering unnecessary both the concentrator and the cyanide process.

In connection with the sluice shown in the illustration, there has recently been introduced into this laboratory, a new system of assay by electrolysis. It has been found perfectly reliable for a number of determinations which aid greatly in arriving at a knowledge of the conditions necessary to perfect work on a larger scale, as well as in giving the exact values of ores and sands operated on. This electrolytic system of assay takes the place of the fire assay in its control of the amalgamation process, as it is found as reliable as the latter in its determinations, and is more flexible in its range of work, as it may be operated equally well on quantities as large as ten assay tons, as on one-fiftieth of that amount.

As this forms a part of the same electrolytic system as the larger apparatus, and is controlled by the same conditions, the electrolytic assay serves as a reliable check on larger operations.

There are certain limitations to the perfect work of the electrolytic amalgamation system. In common with all processes, there are conditions which must be complied with, in order to obtain the required results. In the first place, the apparatus must be properly constructed so as to act automatically in its discharge of sands, and to be readily and precisely adjusted to the varying differences in the gravity of ores, and the quantities that may be introduced.

It is necessary that the apparatus be so constructed as to cause no impediment to the flow of sand or difficulties arise. The construction must also be such that every particle of flowing sand must pass between the two poles of the apparatus (the anode and the cathode), or else no perfect work can be done. Such materials must be used in the construction as will not act adversely to the operations or corrode, and lessen the electric conductivity. The dynamo must be of proper capacity, and adapted to the work in density and tension of current, and the recording instruments must be of the proper range, and correctly set up, for without these the operator is as much at sea as the mariner without a compass.

In performing the work it is always necessary that the anode and the cathode be both in connection with the flow of the sand that passes between, or else no work is done. There is no such thing as the 'electrolysed water' we sometimes hear about. All work is done at the anode and cathode surfaces.

Sand from placers generally needs only to be screened from the coarser material to give perfect results; but ores require to be pulverized to the fineness that is found necessary to free the gold from its matrix, a requirement, be it noted, that extends to every hydro-chemical process where a full recovery of metal is required. In the electrolytic amalgamation system, each ton of ore, of whatever kind, is handled and finally disposed of in less than 15 minutes.

Commercial Paragraphs.

The KELLY FILTER PRESS Co., Salt Lake, Utah, has installed a filter press in the Star mill, Cherry creek, Nevada.

J. V. N. DORR, Denver, Colorado, reports among other recent sales of the Dorr Classifier; shipments made to Costa Rica, France, South Africa, and Ecuador.

The TRAYLOR ENGINEERING Co., Allentown, Pennsylvania, has opened an office in the Newhouse building, Salt Lake, Utah, with William T. Stephens as manager for Utah, Idaho and Montana.

The SULLIVAN MACHINERY Co., Chicago, announces that the Northern Canada Supply Co., Ltd., Cobalt, Ontario, has been appointed as its agent for the northern Ontario territory. The Rossland, B. C., agency of this firm is now in the hands of the Rossland Engineering Works.

EDITORIAL.

TO date Mr. Peary seems hardly to have established the proposition that Cook should be spelled with an r.

BY ERROR two papers appearing in this issue and read before the American Mining Congress are marked as written for the MINING AND SCIENTIFIC PRESS. We may only claim that they were written for us, in common with all others interested in the mining industry. We regret that we do not have more frequent exclusive contributions from Mr. George Otis Smith and Mr. J. A. Holmes, the authors, but are glad to share, at least in publishing such good material.

SILVER is not to become an issue. This we judge from the cool determination of the men who refused to give it standing at the American Mining Congress. The appeal was made to those interested in the expansion of Oriental trade, but the alliance failed. We say this without feeling or prejudice. The silver miners find hardships in the present situation, and Mr. Moreton Frewen and his friends may be right in regard to the need of bi-metallism; but the beginning of a period of business revival would be an ill-selected moment for introducing uncertainties into the financial world. The American Mining Congress has, at least, displayed sound business judgment.

REPORTS have been current that negotiations were being conducted for the sale of the great Oroville, Marysville, and Folsom dredging properties in this State to English capitalists. The rumor also mentioned the sum of \$40,000,000, and connected the house of Wernher, Beit & Company with the transaction. The truth or falsity of this we have not ascertained, but we believe the rumor may have arisen from the fact that Mr. Eugene de Sabla recently offered several million dollars' worth of Natomas Consolidated bonds on the London market, and that Mr. Charles M. Rolker is now examining the dredging ground in the interest of the prospective underwriters.

SIGNIFICANT of the opinions of the leaders of copper production at Butte, Montana, was the attitude taken at the time of the recent strike. It afforded an opportunity to limit the output by closing some of the mines, but work was universally resumed as soon as the engineers and miners had settled their differences. One of the most encouraging spectacles in the metal world for more than a year past has been the bold expansionist policy shown by Mr. John D. Ryan and his associates, despite the unfavorable condition of the copper market. It dem-

onstrates that this powerful group of capitalists has analyzed the complex conditions of the manufacturing world on which the demand for copper depends, and that signs of growing prosperity are perceived.

BONDS are recommended by Mr. Taft to furnish funds for completion of the reclamation projects under way. It is proposed to ask Congress to issue them to the amount of \$10,000,000 and to provide for payment out of future receipts from the sale of the land. This seems a happy solution of a real difficulty. It is, we believe, important to preserve in the reclamation work the principle of repayment by the land, of the money spent on its improvement.

SOUTH AFRICAN milling practice is in a state of steady and rapid evolution. Amalgamation in the battery of the stamp-mill has practically been discontinued, and the tendency to use stamps exclusively for crushing has led to great increase in their weight. Furthermore the teaching of experience with crushing of Rand ores for tube-milling has shown that better results are obtained by employing screens as coarse as No. 3 mesh on the battery. This naturally admits of large tonnages. Tests are also being made with long-headed, short-stemmed stamps, the boss-heads being 48 inches and the stems 13½ feet long. If this continues we will yet see the short, thick stamp which Dr. Rossiter W. Raymond prophesied as much as 25 years ago.

GOVERNMENT operation of the so-called Provincial Mine on the Gillies Timber Limit in the Cobalt district of Ontario has seemingly proved a failure, and the property has been sold to the highest bidder. Mystery has surrounded the management of this mine from the beginning, and the reason for such secrecy has not been apparent. Errors openly confessed would have cast less reflection upon the Government than such shrinking from public inspection. In fact publicity is beneficial to both enterprise and manager. It compels careful economical work. If the officials cherished utopian dreams of winning riches which would reduce provincial taxation they have been awakened to a cruel disappointment; if there were darker dreams, the daylight of reality has sent them flying to their proper limbo.

CALIFORNIA was well represented at the Gold-field meeting of the Mining Congress. The San Francisco delegation, traveling in special cars and accompanied by a band, arrived early on the scene. At first there was much good natured comment on the absence of delegates from Los Angeles, but later in the week they arrived in force. Mr. E. H. Benjamin responded to the address of welcome on behalf of California recalling gracefully the many ties between Nevada and the Golden State. Mr. W. C. Ralston and Mr. Herman Zadig delivered addresses which led to much discussion. Mr. Douglas White served on the resolutions committee and many other Californians made themselves useful. Los Angeles has extended an invitation to the Congress for next year and the invitation is heartily seconded by the entire State.

HAWAII is to be topographically surveyed. The making of topographic maps is necessary to systematic development of the water resources of the islands through storage, and Mr. Robert Marshall, chief geographer of the United States Geological Survey, has gone to plan the work. Similar maps are sorely needed in developing the mineral resources of the Philippine islands. The excellent Bureau of Mines at Manila is more than loaded with work and it seems that there is here a proper field for Federal aid. The co-operation between the Geological Survey and the various States in the making of topographic maps has been particularly helpful and successful. The sooner the resources of the Philippines are developed, the sooner the United States will be free from numerous vexatious problems.

CHINA is again in the public eye. The recall to Washington for further instructions of Mr. C. R. Crane, the newly-appointed American minister, on the very eve of his sailing, was an extraordinary step, and has led to much speculation. It is well known that America desires to be especially friendly to China, and it is said that Mr. Crane's instructions were in general terms "to do anything helpful to China." Chinese diplomacy is, however, of such sort that this is not always easy. It is believed that Mr. Crane's journey to Washington for conference is in relation to the railway situation in Manchuria. The Imperial Railways of North China have proved to be one of the most profitable railway enterprises in the world. The lines are 600 miles long and the ratio of expenses to earnings only 28%. Net returns for 1908 were \$7,992,110. Profits are being used for railway extensions, and quite naturally China is trying to recover some of the concessions earlier given to Japan and other powers. It is worth remembering, however, that in the Fakumen incident a deliberate effort was made to involve England and Japan in a dispute and that fullest investigation showed the Japanese contentions to be well founded. One of China's skilled diplomats, Tang Shao Yi, a Columbia graduate as it happens, when questioned by the American Minister at Peking concerning the famous secret treaty with Japan, since published, denied its existence, although he was himself concerned in its negotiation. Americans sympathize with China in her present difficulties and wish their neighbor well, but it is needful at times to recall Truthful James' sage remarks on Chinese ways.

Protecting Mine-Investors.

The prime reason for interest in the protection of mine investors is to save the mining industry from being used as a basis for systematic swindling. There is no particular reason why special consideration should be shown to the weakness of those men and women who blindly rush into speculation in mining shares. Nevertheless, since the aim in milling is to obtain appliances that are 'fool-proof', an idea is growing that mining stocks must also be made as nearly 'fool-proof' as possible. If we are frank with ourselves we must admit that the ultimate purpose is to inspire public confidence, thus attracting into mining those great reserves of capital which are now persistently withheld from investment in

the mineral industry through fear of insecurity. Let us be even more frank and admit that the agitation now being made, and which has recently received the formal endorsement of the Mining and Metallurgical Society of America, is not divorced from a keen sense of personal advantage. Pecuniary benefit is certain to accrue to the mining engineer from the greater protection which may be thrown about capital utilized in mining ventures. Selfishness is a motive that leads to action, and it seldom can attain its ends without helping others in passing. What is to the advantage of the mining engineer is certain to be to the advantage of the capitalist. The engineer above all things desires permanency and profitability in mining operations. The capitalist desires the same.

It is manifestly proper, then, that a representative body of mining engineers should establish a basis for annual reports on operating mines. The greatest mines of the world are under the charge of mining engineers, and many of them are managed by the very men who have endorsed this resolution. What they practice will necessarily be emulated by others, and a healthy growth of custom must result. The details of the plan are given in another column of this issue. The report, according to this formula, would consist essentially of three parts: the manager's statement of the history of the property, with a detailed account of operations for the fiscal year under consideration; a demonstration of future expectations, based on ore reserves; and finally a directors' report dealing with the finances of the company, and giving a statement of outstanding shares, the classes and respective rights of such shares, with the usual balance sheet. This is not elaborate, but it is infinitely more than most stockholders ever see today. It would assuredly tend toward safety, and the recommendations of the Society should meet with cordial response.

President Taft and Shipping Rates.

Presidential utterances sometimes point the way to action, and a declaration of important policies was anticipated from Mr. Taft in San Francisco. The speech delivered at the Hotel Fairmont banquet on October 5, however, was lacking in this respect. It was jovial, and replete with those conventional commendations which are pleasing to local pride, but it left untouched the greater problems which engage the serious thought of men on the Pacific Coast. The complications suddenly arising in the Far East at the very moment of his visit rendered a discussion of Oriental trade and a naval program impossible. The only hint thrown out was that the maintenance of an adequate fleet on the Pacific could not be done at the cost of leaving the Atlantic sea-board undefended. The inevitable conclusion is that more ships are needed, a fact transparent to any man who has grasped the plain teachings of experience in the past. No great merchant marine has ever yet endured without a navy powerful enough to compel peaceful respect for its existence. We are interested to note in Mr. Taft's address a frank recognition of the need of encouraging our shipping industry. He handled the question with delicate touch,

making but a single definite recommendation. He would utilize a profit of about \$8,000,000 per annum from the foreign mail service in paying mail subsidies to promote the development of other steamship lines to the Orient, to Australia, and to Spanish America. This is good as far as it goes, and it may lead to important results, but it furnishes no broad outlook. The matter of foreign shipping is full of complications, and the mere paying of a bonus is not enough to call forth a merchant marine which will give us independence in international trade. The policy of the railroads has been to stifle not only lines sailing to foreign ports, but coastwise and internal water transportation as well. The principal steamship lines belong to the railroads, and serve as a menace to competition, by displaying the signal of disaster for whomsoever would attempt to encroach upon the field thus occupied. No man can say what proportions our shipping would have grown to if untrammelled opportunity had been presented. Manifestly it must be made illegal for any railroad to discriminate against water transport lines as a condition precedent to any large development of shipping. In other words, any line which may be established must enjoy the advantages accorded to the most favored existing line, thus automatically bringing all to the same level.

Even the United States Government has not guarded the welfare of the people against discrimination, with the opportunity it has through ownership of the Panama railroad. Only after a hard struggle were the rates on that road made independent of the rates fixed by the transcontinental railroads. Until recently the rates at Panama fluctuated in sympathy with them. Even today curious discriminations are found. For example, the rate across the Isthmus, that is, the Panama Railroad's proportion of the through rate, on machinery from New York is \$4 per ton when the goods are consigned to Central American ports, while the charge is \$8.10 when the machinery is destined to San Francisco. This is not a solitary case. Machinery coming from Europe to San Francisco pays \$4.59 per ton for transit at the Isthmus of Panama, while only \$2.97 is exacted when the consignment is made to Guayaquil, and \$3.64 when billed to Central American ports. Mr. B. N. Baker recently called attention, in the *Manufacturers' Record*, to these unjust discriminations as applied to hides. The same is true of many other articles, the rates imposing a distinct disadvantage upon the Pacific Coast, which tends to leave the railroads in undisturbed control of transcontinental freight. If this is an example of the manner in which the Government safeguards the welfare of the people, we can but doubt whether the proposed distribution of \$8,000,000 of mail-profits would not be for the benefit of the steamship lines now owned by the railroads, without leading to any increase in the number of ships flying the American flag. The principle of encouragement for a merchant marine is only an expansion of the principle of protection enjoyed by a multitude of industries, but legislation toward that end must take account of the fact that the same conditions which have hindered the normal growth of shipping will continue active unless the law renders healthy competition possible.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

W. K. BETTY is in London.
E. R. BUCKLEY is at Los Angeles.
CHARLES BUTTERS is in New York.
F. L. RANSOME is at San Francisco.
EDWARD ORTON is in San Francisco.
T. G. Gerdine has been in San Francisco.
J. A. HOLMES has gone to Seattle, Washington.
GEORGE OTIS SMITH is visiting Pacific Coast points.
R. J. FRECHEVILLE has returned to London from Mexico.
A. H. BROOKS reached Washington October 6, from Alaska.
REGINALD C. H. COOKE is on his way to Salisbury, Rhodesia.

U. S. GRANT has returned to Evanston, Illinois, from Alaska.

F. W. DEWOLF has been visiting Goldfield and San Francisco.

T. N. STANTON has returned from Mexico, and is at Globe, Arizona.

A. ROY HEISE is with the Union Oil Co., at Port San Luis, California.

F. KARL LAMB is at Edwardsburg, Idaho, for the Eagle Mining Company.

R. H. ELLIOTT has moved from Sacramento to Marysville, California.

A. E. DRUCKER is visiting the mines of the Transvaal, South Africa.

F. L. BOSQUI and AUDLEY H. ACKERMANN sailed for South Africa on September 11.

F. W. OLDFIELD has gone from Idaho to Hostotipaquillo, State of Jalisco, Mexico.

GEORGE F. MILLIKEN has removed from Jamestown, Rhode Island, to New York City.

E. D. LIDSTONE has returned from Cordova, Alaska, and is now in San Francisco.

CHAS. J. BANDMANN has finished his examination of British Columbia properties and is now in New York.

J. B. EMPSON, of Guanajuato, has recovered from typhoid fever in Mexico City.

JOHN MORGAN has been appointed manager of the South Kalgurli mine, at Kalgoorlie.

C. H. GREIME has left Fairbanks, Alaska, and will reside in Seattle during the winter.

LUIS BASABE, of the Guadalupe de los Reyes mine, Sinaloa, Mexico, is in San Francisco.

HERMAN GARLICHs will reside hereafter in New York City, instead of Perth Amboy, New Jersey.

JOSEPH RALPH is consulting engineer for the Russian Collieries Co., operating in southern Russia.

A. W. EDELLEN is superintendent for the American Smelting & Refining Co. at Anganguero, Mexico.

DAVID MCCLURE is returning from London to San Francisco by way of the Trans-Siberian railway.

FRANCISCO TARRIBA, manager of the Jesus Maria y Piramide mine, Sinaloa, Mexico, is visiting San Francisco.

G. H. COX is assistant professor of mineralogy and petrography at the Missouri School of Mines, Rolla, Missouri.

FRED T. WILLIAMS, of Park City, Utah, has been inspecting mines in the Ely and Hamilton districts, Nevada.

MARTIN MCLEISH, of Denver, Colorado, is testing the tailing at the Los Reyes mill, Peras camp, Oaxaca, Mexico.

JAMES JOHNSTON, of the Butters companies, passed through San Francisco from Copala, Sinaloa, to New York.

N. O. S. FORD has re-opened engineering offices in Oaxaca, Mexico, after a considerable absence in the Black Hills of South Dakota.

H. A. KENNEDY is building the mill and cyanide plant of the Yoquivo Development Co., in Chihuahua. He has just returned from Cerro de Pasco.

MAURICE CLARK has returned from England, accompanied by S. A. Crossley, of London, who is examining Mr. Clark's Sierra Juarez properties in Oaxaca, Mexico.

L. M. PRINDLE, A. G. MADDREN, and C. E. ELLSWORTH, of the United States Geological Survey, have arrived in Seattle from Alaska and will return at once to Washington.

J. A. PARKER has returned from Cortez, Nevada, and will sail, October 11, for Corinto, having accepted a position on the staff of the La Leonesa mine at Matagalpa, Nicaragua.

General Mining News.

ARIZONA.

COCHISE COUNTY.

The Eastern stockholders, headed by John Lonergan of Bristol, have agreed to raise the money necessary to carry on the development of the Bisbee-Sonora mine at Shamrock in the Chiricahul mountains. Over \$65,000 has been expended on the property and several veins of smelting ore opened.—A good grade of lead carbonate and sulphide ore was opened by the cross-cut from the winze at the John A. Duncan group in the Paradise district. Several assays have run as high as 27% lead with some gold and silver. The present ore was cut at a vertical depth of 135 feet.

GILA COUNTY.

The Schulze group, nine miles west of Globe and three-quarters of a mile from the Live Oak, has been bonded to a company headed by Samuel Newhouse and John Dern for \$250,000, payable in 1911. A two-compartment shaft has been started and two churn-drills ordered to prospect the

Map of Arizona.

property which has been opened by several adits and shallow shafts. J. C. Dick will be in charge of operations

GRAHAM COUNTY.

Operations are to be resumed at the Morenci Mesabi property west of Morenci. Considerable work has been done on the claims and some rich silver ore shipped to the El Paso smelter.—The foundation for the Gold Belt mill has been completed and the machinery is being hauled to the mine. The pipe for the new water line has been purchased and it is expected that the plant will be in operation the early part of November. J. Blackstein is working the property under a lease.

MOHAVE COUNTY.

The mill of the Redemption Copper Mining & Milling Co. is to be started this month. Roe J. Ferguson is manager.—Estimates are being made on the expense of constructing a pumping plant to bring water from Silver creek to the Pioneer mines at Oatman.—Work is to be resumed at the White Hills mine. John F. Jones is superintendent.—A. E. Walker is shipping chrysoprase from his property west of Chloride to Denver.—At the Red Gap property the company is opening a 15-ft. vein that assays \$20 per ton.—L. D. Godshall has purchased the Bryan mine at

Stockton hill and the Little Jimmie property in the Union basin district. At the Bethel and Silver mines a 200-ft. shaft is to be sunk and the vein prospected at that depth. Thomas McGraw is in charge of the work.—The mill at the Gold Road mine, at Gold Road, is practically complete and will be started about the middle of this month.

YAVAPAI COUNTY.

(Special Correspondence).—The Arizona Mining Code Commission, consisting of W. L. Clark, of Jerome; W. F. Staunton, of Tombstone; Thomas Armstrong, of Phoenix; Mr. Campbell, of Crown King; and D. J. Hipple, of Globe, will meet at Phoenix, October 14, to formulate a code of laws and regulations to pertain especially to underground work and methods for safety. The commission's report will be submitted to the Governor, and by him to the Territorial Legislature at its next session.

Phoenix, October 2.

The Copper Creek Development Co. has installed a Star drilling rig at its property, 30 miles northwest of Hillside, to prospect the ground. The company's holdings are six miles long by four miles wide in the Eureka district, and the company is to install 11 more drills shortly.—The force at the Dividend mine, in the Big Bug district, has been doubled and the mill is being put in order for continuous operation. F. E. Biles is manager.—Plans are being drawn by W. Spencer Hutchinson, consulting engineer for the Vulture Mines Co., for a 20-stamp mill which will later be increased to 60 or 80 stamps. The shaft has been sunk to the 600-ft. level and drifts started on the vein which is 16 ft. wide and approximates \$20 per ton.—Dyson & Griffin shipped a \$700 gold bar and 12 tons of \$100 concentrate from the Capitol mine, in the Walker district, which they are operating under bond.

YUMA COUNTY.

The St. Louis Post Despatch, through W. G. Steigers, the manager, has purchased the property of D. W. Hall and R. C. Robinson in the Salome mining district for \$150,000.

CALIFORNIA.

BUTTE COUNTY.

(Special Correspondence).—The controversy between local dredge operators and the City of Oroville has taken on a more determined aspect. The attempt to prevent the Ophir Gold Dredging Co. from operating within the city limits has been checked by the granting of a temporary injunction by Judge Morrow, of the U. S. Circuit Court of San Francisco. The Indiana and Pennsylvania companies are also in trouble with the city governments.—The present season is one of the most prosperous that the local dredgers have ever known. Plenty of water is available and there is no danger of a suspension of activities owing to lack of power. Several new machines have been built this year.—The Mammoth Channel G. M. Co. in the Magalia district has completed the installation of its new plant in the main adit. The work of sinking the shaft to bedrock will shortly commence.—At the Blue Hog a compressor, machine-drills, and power plant has been completed.—The adit at the Magalia Ridge is in a good grade of gravel.—It is announced that the Northern California Mining & Development Co. will resume work on its Butte county properties. E. B. Jackson is president.—The management of the Steffer Mining Co. recently announced that active production will soon be commenced.

Oroville, October 5.

INYO COUNTY.

At the Gray Butte mine, southwest of Benton, the company is opening a 6-ft. vein of fair milling ore. George E. Austin is superintendent.—The transmission line at the Casa Diablo plant has been re-built to carry a higher voltage. The power plant is nearly complete and the power will be turned on in a few days.

MONO COUNTY.

(Special Correspondence).—The Golden Cycle Mining & Milling Co. and the Boston Masonic Mining & Milling Co. have been consolidated, and will operate as the Monalda Mining Co.—The difficulties between the True Friend and Jump-up-Joe companies have been adjusted, and work re-

sumed on both properties.—On the Sereta a small body of high-grade gravel has been cut.—The United States Gold Corporation is arranging for additional work at the Sunny Jim and adjacent groups.—Rich discoveries of gold-bearing ore are reported from the Desert creek district, about 15 miles from Bridgeport.—It is announced by Mr. Webber, manager of the Standard Consolidated mines at Bodie that operations will be resumed below the 800-ft. level. Powerful electric pumps will be installed.

Masonic, September 30.

NEVADA COUNTY.

(Special Correspondence).—The 200-ft. winze from the 3500-ft. level of the Empire has cut a body of good-grade ore. The mill is running steadily and the production is said to be approximately \$55,000 per month.—It is rumored that the North Star Mines Co. is arranging to resume operations at the Massachusetts Hill mine. The regular quarterly dividend of \$100,000 has been declared by the North Star Mines Co.—The Eureka mine has not been sold to Oakland capitalists, as formerly stated, but the property is being inspected, though nothing definite has been accomplished.—The orebody opened in the north drift from the 400-ft. level of the Kenosha is only a few inches wide, but assays well.—Cross-cutting for the vein will be soon started from the 700-ft. level of the Idaho-Maryland. On the 400 and 500-ft. levels it is 6 to 8 ft. wide and runs about \$20 per ton.—The owners of the Yellow Metals mine have let a contract to the Miners' Foundry of Nevada City for a small mill. A good tonnage of rich ore has been opened.

Grass Valley, October 5.

A 6-ft. vein of \$10 ore has been discovered on the Butler ranch in the Grass Valley district. The property is owned by W. A. Fields, of San Francisco.

SAN BERNARDINO COUNTY.

(Special Correspondence).—The Garvanza Mining & Milling Co., controlled by Michigan men, began 3½ years ago to develop a group of nine claims situated five miles west of Leastalk station, and now have 2000 ft. of development completed. This opens a series of quartz veins, cutting through pegmatite granite. The veins are 20 to 75 ft. in width, and contain a complex ore of silver, copper, gold, lead, molybdenum, and thorium. The value of the silver, copper, and gold is about \$15 per ton of ore; the rare metals amounting to 0.5 to 1%. A mill of 100 tons capacity has been erected and is in operation. It is equipped with crusher, rolls, trommels, and Standard concentrating tables. The tailing, which contains some gray copper, molybdenum, and thorium, is chemically treated; and it is stated that after the lead is separated from the rest of the concentrate the remainder of the product is to be calcined, then leached in a new plant. H. M. Banfield, superintendent for the company, states that their method of treatment has been developed by tests at the mill and laboratory, and he is now satisfied as to results. The thorium is in the form of a nitrate and is worth \$14 per pound. The company is figuring on erecting a steam-electric power plant, in which crude oil will be used as fuel. The calcining and leaching plant to be erected will have a capacity of 30 tons of concentrate per day.

Vanderbilt, October 2.

SAN JOAQUIN COUNTY.

A flow of natural gas was struck while sinking a well on the property of T. A. Jordan near New Hope and a company has been organized to sink a bore-hole to see if the gas exists in commercial quantities.

SHASTA COUNTY.

Nineteen laborers filed labor liens against the Delta Consolidated Gold Mining Co. and the Inca Treasure Gold Mining Co., operating near Delta, pending the settlement of a suit which has stopped operations at the Delta Consolidated property.—The Yosemite Dredging Co. is building a dredge on the Sacramento river near the mouth of Salt creek. The boat will be 28 by 62 ft. and the dredge will be of the suction type.

SIERRA COUNTY.

The Sierra Mining Co. has put a new skip in the shaft

at its mine near Pike City.—The Omega Mining Co. has purchased the Casserly interest in the Manzanita gravel mine. The property joins the Omega group on the west.—The Sierra Buttes company has 10 men at work re-timbering the No. 6 adit of the Sierra Buttes mine near Sierra City.—At the Cleveland mine, in the Sierra City district, the mill is being repaired and an air-compressor installed. W. Warton is manager of the property.—The 3-stamp mill for the Oakland mine has been shipped to Sierra City, and will be hauled to the mine in a few days. There are 40 tons of rich milling ore on the dump.—A new vein has been cut recently at the Papoose mine, in Jim Crow canyon, that mills about \$8 per ton. The mill will be started under the direction of F. A. Maltby.—A drift has been run on the vein cut on the lowest level of the Gray Eagle mine and cross-cuts driven. The ore is 12 ft. wide and contains a large amount of sulphide. Edward Westall is superintendent.

TUOLUMNE COUNTY.

The electric power line is being extended from the Soulsby mine to the Draper property. A drift has been started on the vein recently opened on the 400-ft. level of the Soulsby.—A new shoot has been cut at the New Albany mine and the ore is being sacked for shipment.—A rich stringer of ore was cut at the Mangante mine, near Jamestown, while sinking a well on the property.—The main shaft at the Jumper mine is being re-timbered and it is reported that the company is planning a large amount of development.

YUBA COUNTY.

The Black Swan, near Smartsville, has been unwatered and the stopes are being sampled to determine the trend of the ore. On the lowest level the shoot has been opened and the company will prepare to commence stoping there shortly. Some good ore has been opened also at the Marc Anthony mine in the same district.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—The Argentine Exploration Co. has purchased the Mammoth group of claims on Leavenworth mountain and will commence shipping shortly. B. J. Martelon has been appointed manager and states that at an early date work will be commenced on a 25-ton mill.—A new vein has just been cut in the heading of the Prudential adit.—Work was put under way this week upon the Queen City property. G. W. Teagarden is manager for the new company.—W. Farragher, leasing the Astor mine, is shipping high and medium-grade ore. The first-class product mills from 400 to 450 oz. silver per ton, while the lower-grade is worth \$40 per ton silver and lead.—Bryant & Co., leasing the Hercules level of the Seven-Thirty mine, have cut an 8-in. streak of smelting ore that assays 650 to 700 oz. silver per ton.—Work has been resumed upon the holdings of the Ruby-Argentine Mining Co., in the Peru district. L. W. Vidler is manager.—The building of the new mill of the Western Metals Co., which is to be equipped with the Malm process, is progressing in a satisfactory manner. One of the buildings is completed, while the second will be finished about October 15. It is stated that the machinery will be shipped some time during the next two weeks.—Hafer & Co., leasing on the third level of the Little Mattie property, have cut an 8-in. streak of rich ore. A carload sent out last week was settled for at the rate of \$300 per ton.—J. N. Bradley, of Idaho Springs, has taken a lease upon the Victor mine on Seaton mountain.—A rich find is reported from the Chicago Belle property of the General Consolidated Mining Co. on Onicago mountain.

Georgetown, October 4.

GILPIN COUNTY.

A contract is to be let to sink the Cook shaft of the Fifty Gold Mines Co. 200 ft. This will make a total depth of 1600 ft.—A new shaft-house has been erected at the Alps mine on Quartz hill and an 80-hp. boiler added to the power plant. Recent shipments of ore to the Chamberlain sampling works assayed: gold 15 oz., silver 54 oz., copper 12%; and gold 6 oz., silver 25 oz., with 5% copper.—L. G. Nesmith is unwatering the Kirk mine on Quartz hill and operations will be resumed. The mine has a record of pro-

ducing high-grade pitchblende and uranium ore.—The Tungsten Mines Co. shipped a carload of concentrate to Denver last week, and it is understood that this company will now be on the list of regular shippers.

GUNNISON COUNTY.

Reinhardt Holloway has opened an orebody on his property in the Gothic district that assays 12% copper.—A cross-cut is being driven in the Blain mine to open the orebody near the old shaft, and the company is repairing the dam at the mill which was damaged by the high water last winter. Archie McLeod is superintendent.—C. C. Bruner is preparing a shipment from the Sunnyside group of 50 tons smelting and 80 tons milling ore.—Charles Young, of Monmouth, has purchased the Gothic smelter and is making arrangements to have the plant remodeled.—The Victor mine at White Pine has been sold to the Miami Mining Co. of Boston.

LAKE COUNTY.

A Denver company, for which C. E. Dewey is manager, has purchased the old plant of the Harrison Reduction Co. in Leadville, remodeled it, and will operate on the iron-zinc-lead ores of this district. The Boston-Arizona Mining & Milling Co. installed considerable machinery in the plant several years ago, but it was not a commercial success at the time. It is now thought that the plant can be made to pay on account of the tariff on zinc ores. The initial capacity will be 75 tons per day.—A rich seam of ore was cut by the winze in the St. Louis adit at a depth of 150 ft. J. B. Stewart is manager.—The Ontario adit at Twin Lakes has cut two new veins recently and stoping has been started on each.—The Blanche mine is being re-opened by George Champion and associates.—The Vinnie property has been equipped with new machinery and is shipping regularly through the Yak tunnel.

OURAY COUNTY.

The drift from the Atlas workings on the Klondike vein is still in a rich silver ore.—A 3-ft. vein of which 14 in. is high-grade copper ore has been opened near the surface at the Honey Comb property at Ironton.—The Mono-Baltic Mining & Smelting Co. has let contracts for the grading and construction of its new smelter at Ironton. The contract for machinery and building material has also been let.—The shaft at the Legal Tender cut the sandstone at a depth of 132 ft. and is expected to open the Mineral Farm vein within 40 ft.—A 2-ft. vein of high-grade copper ore has been opened on the Kentucky Giant mine near Ironton by DeGolyer & Foreman, who are operating the property under lease.

SUMMIT COUNTY.

The Wellington Mines Co. has installed a Card concentrating table in its mill and a new electric locomotive between the mine and mill.—The new mill recently erected by Edward Jones at the Arctic mine is running regularly and the management is preparing to accept custom ores.

TELLER COUNTY.

Mathew Wilhelm has opened the southern extension of the Cookery vein on the Prince Albert company's property on Beacon hill. The ore was uncovered at a depth of 15 ft., and assays from \$18 to \$30 per ton.—A. B. Whitmore and associates have secured an 18 months' lease on the Anna May Wells property.—The Western Investment Co. has secured a lease on block 28 of the El Paso Consolidated Gold Mining Co.'s Little May mine.—The annual stockholder's meeting of the Trilby Mines Co. will be held in Cripple Creek, October 22. The company is producing 40 tons per day from the Trilby and Ben Harrison mines.—The Worcester ventilating system is being installed at the main shaft of the Raven & Beacon Hill Mining Co. The old shaft is down 500 ft., but no work has been done lately at that depth on account of the poor ventilation.—The Grace vein was opened by the cross-cut on the ninth level of the Rexal Gold Mining Co. It is 6 ft. wide and assays between \$20 and \$25 per ton.—A leasing company has been organized by Denver capitalists to develop the claims of the Phonolite Dyke Mining Co. on Signal hill. There are 50 acres in the group and four veins have been traced the entire length of the property.—A vein of ore assaying \$35

per ton was cut by the 25-ft. shaft at the Ida May property and a shipment has been made to one of the valley plants.—S. Sindlinger shipped two cars of \$40 ore from the 300-ft. level of the Lonaconing mine which he is operating under lease.

IDAHO.

BLAINE COUNTY.

The average of a number of samples taken from the vein on the Clipper group was \$5.77 gold with a trace of copper. The vein has been cut at a vertical depth of 700 ft. and there is an abundance of timber on the property.

IDAHO COUNTY.

Henry Hazlitt and George Trader are to install a 15-ton Huntington mill at their Oliva group near Dixie.—J. Bennett, of Whitebird, has purchased the Red Cross mine and will build a 250-ton reduction plant.—The framework of the new Penn-Dixie mill has been completed and the machinery will be installed in a short time.—Two new dredges have been completed in the Elk City district and will be in operation shortly.—The Eagle Mining Co. has begun grading for a Tremain steam-stamp, concentration, and cyanide mill at Edwardsburg. It is the first mill of this class in this district.

NEVADA.

CLARK COUNTY.

(Special Correspondence).—The cross-cut from the 1100-ft. level of the Quartette has intersected the main vein 400 ft. from the shaft. The mill is running steadily.—A 12-in. vein of milling ore has been cut on the 300-ft. level of the Pittsburg-Searchlight. Some fluorine was found, the first evidence of the mineral in this district.—The Crittenden Development Co. has started work at its lease on Duplex ground. It recently secured the New Year's Gift lease and is sinking from the 110-ft. level to the 500-ft. point, where a connection will be made with the Duplex incline shaft.—The Homestead has installed a compressor, and will sink the 600-ft. Fraction shaft to the 1000-ft. level. Searchlight, October 2.

The Eldorado-Occidental Mining Co. is to install a cyanide plant at its property between Searchlight and Hart.—A 50 h.p. Foos gas engine, compressor and two machine drills have been installed at the White Rock mine.—A cross-cut is being driven west from the 320-ft. level of the Lenape property and drifts run north and south on the vein. W. P. Spittal is manager.—A new surface plant is being installed at the Eureka-Searchlight property.

ESMERALDA COUNTY.

(Special Correspondence).—The Nevada-California Power Co., with four plants at Bishop, from which transmission lines now carry power to Goldfield, Tonopah, Silver Peak, Manhattan, Round Mountain, and other places, contemplate the building of a 100,000-volt line, with steel towers, from Bishop to Ely, a distance of 285 miles. The company's representatives are conferring with Ely operators, and the building of the line depends upon the success of negotiations with Ely people. The present equipment at the Bishop plant is equal to 18,000 hp., and, according to A. F. Dieter, the general manager, this will be increased to 20,000 hp. The demands for power on the part of mining men may be taken as evidence of an improvement in actual mine development in western counties of Nevada.—The Mona Power Co. is planning the installation of a 21,000-hp. hydroelectric power plant on Owens river, 15 miles from Bishop, and the building of transmission lines into Esmeralda and Nye counties. W. H. Leffingwell is chief engineer and manager.

Goldfield, October 4.

HUMBOLDT COUNTY.

(Special Correspondence).—Yellowstone, situated approximately 30 miles south of Winnemucca, is coming to the front as a gold camp. A large number of prospectors are in the district and several good ore-shoots are being prospected. On the Yellowstone claim a high-grade stringer is being opened and the ore sacked. J. C. Campbell is the owner.—On the Yellowstone Addition a 5-ft. vein has been opened at a depth of 25 ft., 6 in. of which are said to run \$200 per ton.—The Kindergarten, Florence, Fairview,

Wihuja and Tyler mines at Mazuma have been closed. L. A. Friedman the manager states that it is impossible to operate the mines profitably while paying the high scale demanded by the local Miners' Union. He further states that Mazuma will be an open camp or the mines will continue idle.—Owing to the inability of owners to interest capital in the mines, operations throughout the Seven Throughs section are practically at a standstill. Most of the properties seem to be fair prospects, but the orebodies are not of sufficient size or richness to attract interest from outsiders.

Winnemucca, October 2.

WHITE PINE COUNTY.

(Special Correspondence).—The Nevada Consolidated has commenced shipping ore from the rhyolite dike at the south end of the steam-shovel pit. Five steam-shovels are at work, two on the overburden, and three in the ore. The capacity of the pit is 6400 tons per day. The installation of the 300-hp. electric hoist at the Ruth workings has been practically completed.—The three-compartment shaft of Ely Central is down 75 ft. A second 40-hp. boiler has been installed.—The Cumberland-Ely still remains closed as a result of the strike of the miners. As the McGill concentrator is taxed to full capacity handling Nevada Consolidated ore the management is in no hurry to resume operations at the Cumberland-Ely.—It is reported that Nevada Consolidated will declare a substantial dividend before the close of the year.—The raising for the new shaft at Giroux Consolidated is progressing rapidly. It is nearly 600 ft. above the 1000-ft. level, where it was started. Some high-grade ore has been cut in the raise.—A new corporation, composed mainly of St. Paul capitalists, has been formed to take over the Gradelmeyer mines at Hamilton. These mines have been opened to a considerable extent, and with ample capital are expected to prove valuable producers. Harvey Hall will have charge of operations.—The fourth reverberatory furnace at the Steptoe smelter has been completed and the fifth will be commenced within a few days. The smelter is at present inadequate to handle the production of the concentrating plant, but within a few weeks it will be in a position to handle the full quantity of ore.—S. W. Eccles, president of the Nevada Northern railway, states that eight locomotives and 100 ore-cars will be added to the rolling stock of the company. This indicates that shipping will shortly start from the Ruth workings, and that the tonnage from the glory hole will be augmented.

Ely, October 4.

UTAH.

SALT LAKE COUNTY.

The 5000-ft. drainage adit at the Flagstaff mine at Alta has been completed. The adit is 300 ft. below the lowest of the old workings to which a raise was driven from the 4000-ft. point. The mine is credited with a production of \$9,000,000 in the '70's, but has lain idle on account of the heavy flow of water till the present company acquired the property.—The Emma Copper Co. has secured the necessary money to pay off its debts and has resumed operations.—The first unit of the mill of the Ohio Copper Co. at Lark will be completed by the end of this month and the company will be in a position to handle over 2000 tons of ore per day. New cars have been ordered for use in the Mascotte adit and a large tonnage is blocked out in the mine. When the mill is completed the company expects to mine and mill 4700 tons of ore per day.

SUMMIT COUNTY.

The Constellation and American Flag mines at Park City have been consolidated and a mill will be erected on the property, which now contains 350 acres of good mineral ground.—The shaft at the New York mine is down 875 ft. At the 1000-ft. level the company will cut a station and start cross-cutting. M. J. McGill is manager.—W. D. Lewis has secured a two-year extension of the lease on the Scott Hill property.

CANADA.

BRITISH COLUMBIA.

(Special Correspondence).—There are three diamond-

drills running at the Le Roy mine.—The shaft on the Golden Rule claim is being sunk from the 35-ft. level. Recent assays of picked ore on this property have run as high as \$90 per ton gold, silver, and copper. Much of the ore, however, is low grade.—During July and August the output of the Trail smelter of the Consolidated Co. was \$985,000, or \$350,000 more than the output for the same months during 1908. An addition is being made to the lead refinery which will increase its capacity from 70 to 120 tons per day. There are now 240 working tanks in the plant and 180 more are being put in, which, with the settling tanks, will make a total of 596 in the building, which is to be 600 ft. long, with a traveling crane running the entire length.—Ten men are working at the Mollie Gibson group, Burnt Basin, which is under bond to a St. Paul syndicate. A large body of \$15 ore has been opened on the property.—The Portland Canal district is active. The second payment of \$18,500 has been made on the Red Cliffe bond. A plant is to be installed on the Portland Canal Mining Co. property, where a concentrator and tramway are now being erected.—Recent properties bonded include the Ajax, Ben Bolt, and McKay.

Rossland, October 1.

ONTARIO.

The cross-cut from the 200-ft. level of the Beaver mine in the Cobalt district opened a 9-in. vein of smaltite ore.—The vein on the 140-ft. level has been opened at a point where the ore assays from 2000 to 4000 oz. silver per ton.—The No. 10 vein was cut at a depth of 72 ft. at the La Rose mine. The ore is 3 in. wide and assays 4000 oz. silver per ton.—After a drift had been run 200 ft. on the 200-ft. level at the Shamrock an ore-shoot of native silver was opened.

MEXICO.

CHIHUAHUA.

The Yoquivo Development company has ordered a complete sectionalized 10-stamp mill for its mine. The ma-

Mexican Patio Process.

chinery is now being manufactured in Chicago by the Allis-Chalmers Co. and will be carried several days on mules after reaching the railway station nearest the mine. The stamps are designed for coarse crushing. The pulp, after concentration on Overstrom tables, will be ground in tubemills, agitated in tall tanks with air, and finally filtered on vacuum filters. Zinc dust precipitation is provided and is expected to be more economical than zinc shaving precipitation. All solutions are handled by triplex pumps and pulp is elevated but once, during filtration.

JALISCO.

The Cinco Minas in the Hostotipaquillo district is being equipped with \$20,000 worth of machinery to carry on development. Some high-grade ore has been shipped from the property by H. E. Crawford, who is in charge of the work.

Stockholders, representing 426,000 shares of stock in the Copper Range Mining Co., operating in the Autlan district, have brought suit to compel Charles D. DuBois, the president of the company, to account for the company's money and to prevent him from removing the machinery.

Special Correspondence.

GOLDFIELD, NEVADA.

Meeting of Mining Congress.—New Officers.—Work Resumed.

Goldfield is still talking about the meeting of the American Mining Congress held last week. The first session was called to order Monday afternoon at 2 o'clock by J. H. Hutchinson, chairman of the local committee, with about 300 delegates in attendance. Little business was transacted during the afternoon session, the time being consumed by the addresses of welcome delivered by C. S. Sprague and others. Responses were made by J. H. Richards, president of the Mining Congress, and by members of each State delegation. The most important detail of the day was the sending of telegrams by the Congress to President W. H. Taft and to Secretary of the Interior R. A. Ballinger, urging a Federal Bureau of Mines, co-ordinate with the Geological Survey.

In the evening the Mineral Palace was opened. Following this, exercises were held in the Hippodrome, where addresses were made by Milton M. Detch, George D. Pyne, J. E. Stubbs, and others.

The attendance at the second day's session was nearly double that of the first day, many of the delegates having arrived on a delayed train. The session was devoted to a discussion of silver and the means of increasing its use. Papers by C. C. Goodwin, James A. Heckman, and Thomas E. Kepner were presented.

A telegram was received from Secretary of the Interior R. A. Ballinger emphatically favoring the establishing of a Federal Bureau of Mines. Following the reading of the telegram were addresses by Francis G. Newlands, George A. Bartlett, and W. F. Englebright. All these addresses were on the subject of the Federal Bureau of Mines, and the sentiment of the Congress was evidently as strongly as ever in favor of the movement. Herman Zadig, of San Francisco, spoke on non-assessable mining shares, taking the stand that the incorporation of mining companies under the laws of States where the non-assessment plan prevails is mainly responsible for so many idle properties in Tonopah, Goldfield, and other Nevada camps.

In the evening there was a reception given at the Goldfield Hotel by the ladies of Goldfield to the members of the Congress and their wives. Short addresses were made by different members, and at the conclusion a banquet was served. Prior to the reception the president's annual address was delivered by J. H. Richards.

The third day's session of the Mining Congress was held at Tonopah, and the delegates spent a busy day taking in the mines and mills and attending to the business of the Congress. The various mining companies threw everything open and took particular pains to show and explain everything. At 3 o'clock the Montana Tonopah Mining Co. had its regular bi-monthly melt of the cyanide precipitate, and the refining room was crowded.

The business session of the Congress was called to order at 3:30 p. m. R. P. Dunlap, chairman of the entertainment committee, introduced the first speaker of the day, Hugh H. Brown, who made an eloquent address of welcome. Edmund B. Kirby, of St. Louis, Missouri, delivered an address on 'The Paralysis of the Mining Districts,' already published in the MINING AND SCIENTIFIC PRESS.

Mr. Kirby's remarks were listened to with attention, but it was evident that his views were not shared by a majority of the delegates. At the conclusion of his remarks, several took exception to his statements regarding assessment work, claiming that both prospectors and owners of ground performed the work in good faith.

'Mine Inspection' was then discussed. The papers on this subject appear elsewhere in this issue.

Peter J. Breen read an informing paper on 'National Mining Laws and their Meaning to the People'.

At 8 o'clock William C. Ralston spoke appropriately on 'Comstock Days'.

J. A. Saunders, of Tonopah, followed, and his tribute to the prospector was one that will be long remembered by

those present. H. R. Cook spoke at length on 'Sane Mining Laws', and in his address took issue with Mr. Ralston relative to the making of mining shares assessable.

The business portion of the meeting was closed by an address on 'Nye County', by Walter D. Cole.

The day's work having been completed the floor was cleared for dancing, and refreshments were served till 11 o'clock, the hour set for the departure of the train for Goldfield.

At the session Thursday the various standing and special committees made their reports. The committee on revision of the mining laws, through W. R. Ingalls, of New York, reported progress. A similar report was made by the committee on coal and taxation by Samuel A. Taylor, of Pittsburgh. The subject was further presented in a paper by G. W. Traer and an address by David Ross, of Springfield, Illinois.

A. D. Parker, of the Florence mine, spoke briefly but entertainingly. The talks of Douglas White, of the Las Vegas & Tonopah railway, and J. F. Kent, of Good Springs, Nevada, on 'Zinc Mining in Southern Nevada,' were postponed till the next session.

The annual election of directors was held Thursday night. The nominating committee consisted of S. A. Taylor, of Pennsylvania, R. L. Riepe, of Nevada, R. L. Herrick, of Colorado, J. A. Holmes, of Washington, and E. A. Carlson, of Idaho. They nominated D. W. Brunton, of Denver, Will L. Clark, of Jerome, Arizona, and George Wingfield, of Goldfield, as directors, and J. H. Richards, of Boise, as a permanent honorary director. They were all declared to be elected for two years.

Later the same evening the directors, consisting of E. R. Buckley, S. A. Taylor, George Wingfield, W. L. Clark, J. H. Richards, and John Dern, by proxy, met at the Goldfield Hotel and elected E. R. Buckley president, John Dern first vice-president, George W. E. Dorsey third vice-president, and John F. Callbreath, Jr., secretary.

Especial interest attached to the sessions on Friday, since various phases of public land problems were then considered. 'The Mining Man's Interest in Land Classification' was discussed by George Otis Smith, Director of the Geological Survey. This address is published on another page. The Forestry Committee of the Congress reported that several conferences had been held with the Forester and numerous difficulties had been adjusted. On one point, however, that relating to the use of timber for mining purposes taken from public land other than the claim upon which it was used, no agreement had been reached. The committee was of the opinion that the stand taken by the Forest Service was illegal, and strongly condemned the Chief Forester. The whole subject was discussed by W. W. Dyar, law officer of the Forest Service, and after further consideration the resolution of censure was defeated. Since the question of the legality of the action of the Forest Service is now before the courts, this action was evidently proper. It is understood that another committee will be named to formulate definite recommendations for change, to be made to the Forest Service and to Congress.

Saturday was devoted to visits to the mines and mills. In the afternoon a rock-drilling contest attracted much attention. The 'Malpais Mix-up' set for Saturday night was given up on account of rain.

Since the Congress adjourned, attention has been re-centered on local affairs. Meanwhile double shifts of miners are working in the caved area above the Hampton stope of the Combination in the effort to recover the bodies of the two remaining miners. The widely circulated story that Reese, whose body was recovered in a cross-cut at 130 ft. depth, was killed by fumes from the cyanide solution in the engulfed tanks, is characterized as ridiculous by J. H. Mackenzie. The solution was of but 0.1% strength, and the rescuing parties were working constantly in it without bad effect. The lower levels leading to the great stopes are being repaired and damage to the mine is slight. A force of men will be employed at once in clearing away the wrecked portion of the mill and in removing the plant in order to begin opening the orebodies immediately beneath. Production from the Combination mine will suffer but small

interruption, while the full capacity of the 100-stamp mill can readily be produced from the Mohawk and Red Top mines.

Production from the Clermont shaft has not yet begun. The comparatively small tonnage taken out in the course of development has shown gratifying value. From the 730-ft. level, where the west cross-cut toward the Mohawk entered the ore for over 250 ft., fifteen cars sent to the mill gave assays from mine sampling of 75.12 oz. and nine cars 91.12 oz. gold per ton. After this cross-cut, following the line of survey to the west, had been in ore of high quality for over 250 ft. the vein turned away to the south, and near this point ground was broken down on the north side of the lateral to provide room for starting a raise toward a point on the 600-ft. level, where rich ore is exposed. The first shots brought down high-grade ore, and a cross-cut was driven through 20 ft. of ore giving mine assays of \$500 to \$2400. As far as has been determined, this ore-shoot, for the entire distance followed, is from 12 to 25 ft. wide and is nearly all far above the established milling grade, with large quantities of exceedingly rich ore. Stopping at this level will begin at once with square-sets of the type used elsewhere in the mines.

SPOKANE, WASHINGTON.

A. I. M. E. at Butte, Anaconda, Mullan, Wallace, Wardner, Spokane, and Seattle.

The special party of members of the American Institute of Mining Engineers arrived at Spokane, September 27, after stops at Butte and Anaconda, Montana, and Wardner, Idaho. At Butte, September 24, the party was met by a local committee headed by B. H. Dunshee and C. W. Goodale. Sight-seeing cars were provided for a trip around the city, and a number of the visitors were taken down to the 1200-ft. level at the Leonard mine. A reception and dance at the Silver Bow Club closed the day and contributed to the visitors' pleasant impression of the city.

Anaconda was visited September 25. The party was met by F. W. C. Whyte, E. P. Mathewson, and William Wraith and shown through the great Washoe smelter. Luncheon at the Montana Hotel was followed by a visit to the Deer Lodge county fair, where display of grain, vegetables, and live-stock convinced the visitors at least that the oft-described 'smoke-devastated' farms of this region are misnamed.

The beautiful Bitter Root mountains between Missoula, Montana, and the Coeur d'Alene district were crossed early Sunday morning, September 26. Mullan, Idaho, was reached about 10 o'clock, and a visit was made to the Morning mine and mill of the Federal Mining & Smelting Co. Most of the time was spent underground, the mine being readily accessible by means of electric cars running through an adit 11,700 ft. long. Following this visit the train was taken to Wallace and side-tracked for the remainder of the day and night. The local committee, Frederick Burbidge, F. W. Watson, and J. F. McCarthy, had provided carriages, and a number of members of the party drove up Canyon creek to the Hecla and Hercules mines.

The first stop on Monday morning was at Wardner, famous as the home of the Bunker Hill & Sullivan mine and mill. Here the party was divided into three sections, the first visiting the mine, the second the mill, while the third, which was composed largely of the ladies, was conveyed by a special train over the 'high line', where the magnificent scenery of the district could be observed. The party which visited the mine, under the guidance of Stanly Easton, had a strenuous morning of it in climbing up and down stopes and man-ways in this, the greatest silver-lead producer in the world. It was nearly noon when the visit was completed, and shortly after that the train was again boarded and the trip to Harrison, on Coeur d'Alene lake, was made by 2 o'clock. The party then left the train and proceeded by steamer across the lake to Coeur d'Alene City, where a special trolley train was in waiting. A stop of nearly an hour was made at Post Falls, where the waters of the Spokane river, coming from Lake Coeur d'Alene, have been harnessed for the generation of 15,000 hp., which is dis-

tributed to the Coeur d'Alene district, and to Seattle, and also used for the operation of the trolley system.

The hour of arrival at Spokane was so late that the opening session of the Institute was postponed till 2 o'clock Tuesday afternoon. The hotels being crowded because of the visit of President Taft, most of the travelers remained on the train while in Spokane.

Tuesday was 'Taft Day', and the Institute met with a rival attraction. The local committee had provided seats for the visiting engineers on the grand-stand, and as no session was fixed for the morning, the members of the Institute had the privilege of reviewing the parade and of listening with interest and approval to the conservation address of the President.

The first session was called to order at the Masonic Temple, by E. J. Roberts, chairman of the local committee. Mr. Roberts introduced J. C. Ralston, City Engineer, who on behalf of the Mayor and of the Chamber of Commerce extended the welcome to the city. Dr. Raymond responded. The real business of the meeting began with the presidential address of David W. Brunton, on the 'Modern Progress

The Coeur d'Alene, Idaho.

in Mining and Metallurgy in the Western United States', already published in the MINING AND SCIENTIFIC PRESS. The paper brought out a lively and interesting discussion. William Kent, late of Syracuse, spoke on the debt the mining engineer owed to his mechanical brother for much of the improvements he has been able to introduce. To this Dr. Raymond responded that the mining engineer had to be not only a mining, but a civil, a mechanical, and an electrical engineer. He must combine the whole. W. S. Ayres, of Hazleton, Pennsylvania, spurred on by Dr. Raymond, gave a brief description of a dry coal washer brought out by him, in which frictional resistance and not specific gravity is the potent factor. Charles Catlett, of Staunton, Virginia, brought up the interesting subject of cost keeping in accurate detail, and W. O. Snelling, of the Technologic Branch, U. S. Geological Survey, told of the work of standardizing explosives. C. W. Goodale, of Great Falls, described the just completed dust-recovery flue and stack installed by the Boston & Montana Co. at a cost of over \$1,000,000, and E. Levy, of Rossland, British Columbia, told of recent improvements made in the mining operations in the Rio Tinto district of Spain. The discussion and the session was brought to a close by an eloquent address on the subject of

electricity versus compressed-air for mine haulage, by W. L. Saunders, president of the Ingersoll-Rand Company.

The evening session was opened with a second paper by Mr. Brunton on 'Modern Practice of Ore Sampling'. Mr. Brunton apologized for presenting two papers on the same day, the second being set for the evening because it was the only opportunity for a lantern illustrated paper. The paper was discussed by Thomas Kiddie, of Northport, Washington, who gave some interesting statistics on the results of sizing before sampling. The only other paper presented at this session was an abstract of one prepared by Franklin Bache, of Fort Smith, Arkansas, on 'Dust Explosions in Coal Mines'. The abstract was presented by the secretary, Dr. Raymond, who took the opportunity to emphasize in no uncertain terms the woeful lack of discipline in our coal mines, and held that the excessive use of powder—one of the most potent causes of coal-mine explosions—was due to the inequity and iniquity of the laws which compelled the payment for mining coal on the mine-run basis. He also incidentally took a fling at the anthracite strike commission as responsible for lax discipline in the anthracite mines of Pennsylvania and among railroad employees, particularly those known as the anthracite roads.

The meeting on Wednesday morning was a joint session of the A. I. M. E. and the Western Branch of the Canadian Mining Institute, and was presided over by the two presidents, Mr. Brunton and Mr. Thomas Kiddie. The first paper presented was by J. McD. Porter, of Spokane, on the 'Ruble Hydraulic Elevator'. It was discussed by Dr. Raymond and Mr. Kent, who also added by their suggestions to the interest of the second paper, a contribution of 'How We May Conserve Our Coal Resources', by Edward W. Parker, of the U. S. Geological Survey. The next paper was one on the 'Coal Resources of Alberta and Southeastern British Columbia', by E. Jacobs, secretary of the Western Branch of the Canadian Institute. Mr. Jacobs also presented an interesting communication on the 'Galt Coalfield of Alberta', by W. D. L. Hardie. This paper brought out some comments from W. S. Ayres. Milnor Roberts, of the University of Washington, Seattle, gave some extemporaneous remarks on the Nicola Valley coalfield of British Columbia, and the session and the Spokane meeting of the Institute was brought to a close by a general discussion of the papers presented during the morning, those participating in the discussion being W. Fleet Robinson, who also spoke on the 'Mineral Resources of Malcolm and Queen Charlotte Islands', and by Charles Catlett, Frederick Keffer, of Greenwood, British Columbia, Mr. Kiddie, Mr. Kent, Mr. Ayres, and others.

In the afternoon the members of the two Institutes were treated to automobile rides about the city and its picturesque suburbs, to the steam-power plant of the Washington Water Power Co., and to the mineral exhibit at the county fair grounds. The final and crowning feature of Spokane's hospitable entertainment of its guests was a brilliant banquet in the evening in the 'Hall of the Doges' of Davenport's restaurant. At the close of the banquet the members of the Eastern party resumed their accommodations in the special train, and about 7 o'clock on Thursday morning proceeded on their way to Seattle. An extra coach was attached to the train for the benefit of the local members and a few of the Canadian party who desired to take this portion of the trip.

The trip from Spokane to Seattle was without incident. The local committee, headed by Chester F. Lee, joined the party at the Washington Hotel. At Seattle, as at Spokane, the mining engineers were somewhat overshadowed by the presence in the city of the President. The morning was spent in a trolley ride on special cars to points of interest in the city, the thing of principal interest to the visitors being the wonderful re-grading of the city by 'hydraulic' away the hills. This is indeed a remarkable example of re-construction of a city. By noon the fair grounds were reached. They keep on schedule in Seattle. It should be remembered that the A.-Y.-P. Exposition was completed on schedule time, the first instance of the kind in the United States, and when it opened, the grounds and buildings had the same finished appearance they have today. An informal

reception and luncheon at the New York building gave the visitors an opportunity to meet the local members and their ladies. On Saturday morning automobiles were provided for a trip through the beautiful residence districts and along the great boulevards, and this afternoon, as the previous one, was left to the visitors to enjoy as they wished. Most of them spent their time in the exposition grounds. Sunday was without a special program, and to a somewhat fatigued party it was indeed a day of rest.

NEW YORK.

Cumberland-Ely.—Consolidation with Nevada Con.—Union Copper, North Carolina.—Davis-Daly.—La Rose Consolidated.

When the Cumberland-Ely company was organized to take over the Veteran mine and other claims at Ely, Nevada, several years ago, the active work of organization was done by W. B. Thompson and his associates, who secured the financial aid of the Guggenheim family of New York. The Guggenheims were not, however, the controlling factors in the company, and have not been until within the past few months. Recently Mr. Thompson is reported to have sold large blocks of Cumberland-Ely, which have passed into the hands of people closely identified with the Guggenheims. The long talked of consolidation of Nevada Consolidated and Cumberland-Ely is now believed to be near at hand, as Cumberland-Ely has fluctuated on the curb market during the past few days. After breaking through \$6 per share, it rose rapidly above \$7.

The Kerr Lake Mining Co. has made public its report for the year ended August 31. During that period the total sales of ore were \$1,382,290. This figure exceeded by \$592,977 the sales for the preceding year. It cost the company \$200,050 to make this production, or less than 8c. per ounce. The ore treated was 1072 tons. The production was 2,668,648 oz. silver. The average silver content per ton of ore was 2487 oz. The company's report sets forth that the cash on hand, together with the ore shipped but not settled for, is sufficient to pay dividends at the present rate for another year, and that the existing ore reserves insure the payment of like dividends for a number of years. One remarkable feature of the Kerr Lake report is that about 75% of the mining costs are shown as representing development and improvements.

A coterie of stock market operators is again manipulating Union Mines. Union Mines is the company which owns the old Union copper properties in North Carolina. The manipulation of Union copper on the New York Curb several years ago was a scandal of the first water. The stock was pushed above \$50 per share, and a large public was drawn to it during the manipulation. The properties of the company have never made any money for dividend account. Efforts, such as those being made, to again milk the public through the medium of a 'lame' stock should be stopped by the authorities.

The Tonopah Mining Co. has declared an extra dividend of 10c. per share in addition to the regular quarterly dividend of 25c. The annual meeting of the Davis Daly Co. has been postponed until October 15. Newman Erb sued for an injunction in Maine against the holding of the meeting on the day regularly set for it, and the Court granted him a stay. The Erb faction claims that it will hold proxies at the meeting to be held on the 15th, sufficient to enable it to oust F. Augustus Heinze and his friends from the directorate of the company. The La Rose Con. Mines Co. reports a remarkable showing on its Lawson properties at Cobalt as a result of the development since June 1. Four shafts are being sunk on the Lawson tract. Shaft No. 1 is on the 'silver sidewalk'. A cross-cut from the 88-ft. level of this shaft has picked up the vein, which is reported to be as strong at that point as on the surface, and has also discovered a blind vein which carries the solid high-grade ore characteristic of this part of the Cobalt camp. Shaft No. 2 has been sunk on what is called vein No. 2. This is a strong vein in the Keewatin formation. The other shafts are on veins No. 8 and No. 11, both in the conglomerate. Vein No. 11 is a comparatively recent discovery. This vein shows a width of 9 ft., remarkable for Cobalt, of which

something over 20 in. is high-grade ore, the balance being a good grade of concentrating ore.

In an interview, Mr. Frank Armstrong states for the company, that no attempt has been made to mine from any of the veins on the Lawson, but that by next spring the Lawson will be the largest producing property of the La Rose company.

BUTTE, MONTANA.

Amalgamated's Attitude Toward Production. — Development in Progress.—Pilot-Butte.—East Side Geology.—British Butte

Ben. B. Thayer, assistant to the president of the Amalgamated Copper Co., is in Butte making an inspection of the properties of the company. It has long been expected, in view of the unsatisfactory state of the copper market, that the Coalition increase would be ordered stopped, but no such order has yet been received. The fact that the Coalition company is permitted to increase its production gradually, taken with the fact that John D. Ryan, of the Amalgamated company, took a personal interest in the recent controversy between the miners' and engineers' unions, and succeeded in bringing about a speedy settlement of the difficulties, plainly indicates confidence in the copper market on the part of the Amalgamated officers. There was a general fear in Butte that the Amalgamated would take advantage of the fight between the unions to close the mines for six months or more, and thus solve the copper accumulation problem, but Mr. Ryan had no such idea, and the re-opening of the mines after the strike had continued three days best indicated his position toward the copper surplus. Mr. Thayer says that while the copper market is not altogether satisfactory, they are looking to the future with hope and confidence. General business conditions all over the world are improving, he says, and while betterment is slow, it is so certain and substantial that it can only be a question of time until every pound of surplus copper is taken and the productive powers of the mines will be taxed to meet the demands.

At the mines of some of the new producing companies production is being increased and a great amount of money is being spent in development. The Tuolumne is gradually adding to its production of ore, while it is developing several veins on the 1400-ft. level. The Butte & Superior company is continuing work, preparing for the erection of its zinc concentrator, with which it will treat 300 tons of ore per day. The Butte-Ballaklava company has nearly completed its big steel ore-bins and is opening four fine veins in its mine on 11 levels down to a depth of 1400 ft. The Pittsmont company (East Butte) is maintaining a good production, and is now operating at a good profit, earning about 70c. per share on its 300,000 shares of stock. With its enlarged concentrator and smelter the East Butte is in position to produce about 10,000,000 lb. of copper per year. East Butte copper costs a fraction more than 10c. per pound, very close to the average for the Butte district.

One of the new companies that finds pastime in holding meetings is the Pilot-Butte Copper Mining Co. The company owns a half interest in the Pilot claim, and \$70,000 is due on the remaining interest, in addition to which the company has other indebtedness amounting to \$85,000, which is secured by mortgage on the property. There is a shaft 530 ft. deep, and cross-cuts have been run on the 300 and 500-ft. levels a distance of about 600 ft. Recent developments in Clark's Elm Orlu mine, adjoining the Pilot, seem to warrant the conclusion that there is prospect of finding commercial ore in the Pilot at a depth of 1000 ft. In order to raise funds to carry on such development work the directors recommend an issue of first mortgage bonds on the property to the amount of \$375,000, payable in three years, and bearing 8% interest. They also propose to use the treasury-stock as a bonus to assist in placing the bonds. Part of the bond-issue is to be used in paying off the existing indebtedness, and the remainder to be used in providing a working fund. The Pilot is a small fraction of a claim, but it is well situated in the midst of producing mines. Recent discoveries of good ore in the Butte & Superior and Elm Orlu mines, which adjoin the Pilot, have

added greatly to the prospective value of the latter.

In the Murray-Switzer case, regarding the prospective value of east-side properties, John Gillie, general superintendent of the Amalgamated company, said that the company was not satisfied that the ground there was not valuable; he also said that the work of developing the Greenleaf mine would be resumed later. The Greenleaf shaft is down 1000 ft., but the veins were found badly broken at that depth, containing no commercial ore, and work was stopped during the 1907 panic. Gillie gave his opinion of several companies operating in that district and said he always considered that the Butte & London company had the least chance of any. In this he does not agree with H. V. Winchell, former geologist of the Amalgamated, who directed the operations of the Butte & London, and made reports on the property that were highly favorable. The Pittsmont company, now controlled by the East Butte, is the only one on the east side that is mining commercial ore.

At a special meeting of the British-Butte Mining Co. the stockholders voted to change the capitalization by reducing the number of shares from 5,000,000 at \$1 per share par, to 250,000 shares of the par value of \$20 per share. Old shares are exchangeable at 20 shares for one. The change was made for the purpose of giving the stock of the company a market standing, and to list it on the exchanges in London and Paris. After a shut-down of several weeks, due to trouble with the company's engineers, the dredge, operating west of Butte, has been started again. Some important changes were made in the tables, as the old ones lost too much gold. It is expected that the new ones will show much better results.

LONDON.

British Interest in Brazil. — Gold in Rio Grande do Sul. — Heawood Tin & Rubber Estate.—Tin Lode.

The gold deposits of Brazil have received more attention in England recently. One of the companies recently formed to conduct operations in that country is the Brazilian Gold-fields, Ltd., to which the firm André Griffiths, Mannheim & Co., act as engineers. The tract of country acquired is situated in the State of Rio Grande do Sul, 175 miles from the port of the same name. Mr. Mannheim has been on the property for some time, and has been developing an area immediately adjoining the mines of a Belgian company called the Société des Mines D'Or du Cerrito. His developments have proved the existence of payable ore, but the amount of work done is small, so that no idea of the extent of the deposits can be gained. The company, however, considers that it is justified in starting work with a 25-stamp mill. For the purpose of raising the necessary capital a subsidiary company, called the Brazilian Golden Hill, Ltd., has been registered with a capital of £150,000, of which £59,993 in shares, and £3500 in cash, go as purchase price to the parent company. The amount of working capital required is £40,000, and the issue of shares representing this amount has been underwritten.

Another new company introduced to the notice of the London public recently is the Heawood Tin & Rubber Estate, Ltd., which has been formed to acquire and develop the property of the Heawood Syndicate, in the State of Perak, Federated Malay States. The property is situated 21 miles from Ipoh, on the route from Singapore to Penang. At the present time there is a craze for rubber among company-promoters, and numerous companies formed for the purpose of exploiting forests in all parts of the world have been placed before the public recently. The Heawood company combines rubber and tin. The tin-ground consists of gravels which at present are worked on tribute. Part are said to be suitable for hydraulic working on a large scale, and it is estimated that £7000 will be required for the necessary equipment. At one part of the property an out-crop has been discovered, and already tin ore that sold for £11,600 has been extracted. Investigations are now being made to determine the prospective value of this lode. The information given in the prospectus is somewhat vague, and it is difficult to form any opinion as to the merits of the flotation.

MEXICO.**Santa Gertrudis.—New Plant.—Negotiation for La Blanca.—Guanajuato Development.—Pan American Railroad.**

The sale of the Santa Gertrudis mine, at Pachuca, State of Hidalgo, to Anglo-American interests principally represented by the Camp Bird, Ltd., is now an accomplished fact. The final meeting of the shareholders of the Santa Gertrudis was held at the Hacienda de Guadalupe, and the terms of the option given to Hugh Rose, were ratified by the vote of 45,572 shares out of 55,670 represented at the meeting. Out of the 60,000 shares of the company it was necessary to have 75%, or 45,000 votes, to make the ratification legal. The margin of 572 shares was, therefore, a very narrow one. The vote of 10,098 shares was opposed to the sale of the mine, but the very large interests held by the Landero family were sufficient to make up the necessary 75% and to decide the vote.

From September 13 to 28 the shares steadily rose from \$80 to \$127. The purchase price of the mine is \$9,000,000, or \$150 per share. It is stated that Hugh Rose, who was lately manager for the Guanajuato Development Co., will be manager of the mines for the new company. The work on the new cyanide plant being erected for the Santa Gertrudis Co. is being pushed vigorously. Newcomb & White are the contractors, and they have already received a large part of the material for the tanks. It is now on the grounds. The foundations are also ready. The riveting of the tanks will be done by compressed air, which will be supplied by an Ingersoll air-compressor. Everything is being done for the speedy completion of the plant.

The La Blanca mine, which was at one time supposed to have been definitely sold to the same parties, and which was afterward denied, is again in the lime-light. It is said that a group of English capitalists connected with El Oro mines are negotiating for the purchase of the mine for the sum of \$6,250,000, and that within 10 days the deal will be either completed or dropped. It is stated that the former deal fell through because the brokers asked a commission of \$900,000, and at that time the stockholders wanted \$6,000,000. If the deal is carried through, it will give added force to the influence and stimulus of the Santa Gertrudis deal on Mexican mining affairs.

The Real del Monte Co., of Pachuca, has taken up 150 pertenencias in the El Chico district, which will have a good effect on industry in that camp, and if this powerful company determines to push development at once it will be of great financial benefit to the district.

The Fortuna mines, near San Pedro Taviche, Oaxaca, are now owned by T. Carrabine, of Kansas City, the titles having been recently transferred.

Governor Obregon Gonzales in his message at the opening of the twenty-third session of the legislature of the State of Guanajuato gave an interesting review of the state of the mining industry of that famous district. He said the highest annual output during last century, was for the year 1850, during the bonanza period of La Luz, when the gross output reached \$8,510,177. At the end of the century the number of reduction plants in operation was 39, all using the patio process, and the average amount treated was 117,500 tons. Today there are 14 modern mills, with a total of 600 stamps, 12 tube-mills, and four Chilean mills, between them averaging over 2000 tons per day, the last years production having reached 746,425 tons, or over six times as much as a decade ago. The investment of foreign capital between 1903 and 1907 amounted to \$20,000,000. The value of the annual output has increased by leaps and bounds in the last few years. From 1905 to 1906 it was \$2,399,209; from 1906 to 1907 it rose to \$4,309,335; from 1907 to 1908 it reached \$7,385,455; and from 1908 to 1909 it passed the \$8,000,000 mark. During the coming year it is expected that the output will be \$9,000,000, or more. The gross production of the State of Guanajuato from 1893 to date has been close to \$93,000,000. The present weekly disbursement for wages and other local outlay is approximately \$100,000. Regarding the future, there is evidence that further large investments will be made. The Oro Grande Mines Co. has been organized by George W. Bryant with a capital of \$9,750,000,

and this company owns and will actively develop the groups known as La Luz, San Nicolás Tolentino, El Refugio, Melladito, and Bolanitos, which have all been famous in the past for their bonanzas. The Guanajuato Amalgamated Gold Mines will shortly invest further capital in the improvement and enlargement of plant, and the output of the mines will be correspondingly increased. The New York & Mexico Mines & Securities Co. has been organized by John Butler with a capital of \$500,000 to work the El Puertocito, El Carmen, Santa Virginia, El Pabellón, and El Patriarca. About \$7000 per month is being expended in preliminary development work. A Mexican company has also been organized under the name of La Compañía Minera de San Antonio Le Chispa y Anexas, for the purpose of exploring in depth for the veins of the famous old mines of La Luz. With this object in view the company is now engaged in sinking a deep shaft. The Republic Mines Co. is also investing further capital and is pushing development at the mines of Barranga and Anexas.

Adolfo Villar, of Torreón, has recently been in Mexico City making purchases to complete the material required for the erection of a 150-ton cyanide plant for the mines at Santa Maria del Oro, Durango. G. A. Denny has completed the sampling of the San Juan mine in the Taviche camp of Oaxaca. If the results of the examination are satisfactory it is understood that the mines will be taken over by an English company and developed on a large scale. Local mining men are, therefore, awaiting the outcome with keen interest, as the sale of this mine will mean much for the future of the camp.

The Tezuitlán Copper Mining & Smelting Co., owning the Ocotes mines in the State of Oaxaca, for some time past has done little else than block out ore, as the cost of transporting to the smelter at Tezuitlán was prohibitive, and the large percentage of silica in the ores made the problem of local treatment at the mines difficult. A solution of these problems must be in sight, judging by the active development now under way. The Ocotes is one of the most important copper mines in the State.

The purchase of the Pan American Railroad by U. S. Ambassador Thompson, has been published in the Mexican daily press as an accomplished fact, though Mr. Thompson states that the details of the arrangement are not yet completed. Work, however, is being rapidly pushed; 70,000 new ties have been ordered from California, and material to build steel bridges, and to repair the damage done in the recent floods; so that within a year it will probably be possible to travel in a Pullman car from Canada to Guatemala. E. M. Wise who has had many years experience in railroad work in southern Mexico is to be vice president and general manager. He is at present in charge of the active construction work. On the Guatemalan side there are still 25 miles of track to be completed, and there is a bridge 2000 ft. long to be built over the Suchiate river. As this river marks the boundary between Mexico and Guatemala, the permission of the Government of Guatemala has to be obtained. As soon as this has been done the construction of the bridge will be pushed as fast as possible. The Pan American Railroad is standard gauge; it starts from Gamboa, Oaxaca, on the Tehuantepec Railroad, and follows the Pacific coast of Mexico to the Guatemalan frontier, a distance of 458½ kilometers. The road traverses a low-lying tableland at the foot of the coast-range, and it runs about half way between the mountains and the sea. The country is tropical and subject to heavy rainfall. So far it is only very slightly developed, but there is said to be great opportunity for mining in the coast-range.

In the message of President Diaz at the opening of Congress, referring to the mining industry, it is stated that during the second half of the fiscal year, 2072 title deeds to mines were made out. Comparing the total number for the fiscal year 1908-1909 with the number in 1907-1908, there is seen to be a decrease of 36%, due in part to the financial crisis and to the low price of metals. Referring to railroads, it was stated that the total length of railroads subject to Federal control was 24,161 kilometers.

Action has been taken by a number of prominent mining men and engineers with regard to the project of mining law which is now before the Senate for ratification. It is claimed that proper provision has not been made with regard to large drainage-tunnel projects. A letter has been addressed to José Luis Requeña, president of the Chamber of Mines, which in part says: "I desire to call attention to the importance and necessity of taking such action as would cause favorable laws to be enacted by Congress, granting liberal benefits, privileges, and protection, such as would insure their construction whenever practical and necessary." There is a project on foot which is largely the motive for this action, and which involves the investment of over \$10,000,000 for the construction of a 12-mile drainage tunnel in the Pachuca district. The proposed amendments, are merely the revival of the provisions of the old law passed November 22, 1884, and repealed in 1892, which made it possible for a tunnel company to be granted a concession by the Government which would give it the right of way to tunnel through a designated mining district. The projected law does not give the Government the power to grant any such right unless the constructing company has the written permission of each individual mine owner, whose property might be affected by the work.

ROSSLAND, BRITISH COLUMBIA.

British Columbia Copper & New Dominion. — Output of Smelter. — Enterprise. — Rawhide Mine. — Granby. — Electric Zinc-Smelting.

The policy of the British Columbia Copper-New Dominion group is slowly but surely unfolding. It is now understood that an arrangement has been entered into for the ore from the New Dominion mines to be smelted and converted into blister copper at the plant of the British Columbia Copper Co. This action has been partly brought about by the influence the B. C. Copper Co. has wielded in view of recent heavy purchases of the securities of the New Dominion Co., but the fact that the New Dominion smelter at Boundary Falls is not well enough equipped to produce low-priced copper matte is probably the chief reason for this arrangement. There are times when corporations, like individuals, have to make the best of a bad state of affairs. This is what the New Dominion has to do today. The company has a big smelter to carry on its books, on which the interest on investment, depreciation, and other fixed charges are heavy; but to start work at the smelter under existing conditions would not decrease these charges; on the contrary, it would probably augment them, and in addition there would be a considerable loss on the ore treated, when compared with the rate that can be secured from the B. C. Copper Co., to whom the Dominion has always gone heretofore, to have its copper matte converted to blister copper. It thereby made a considerable saving in freight. The affairs of the new Dominion, as far as finances are concerned, are now in good form, and there is likelihood of an early start at the mines. The outstanding securities of the New Dominion Copper Co. will be about 250,000 shares of stock, of a par value of \$5, this being the entire capitalization of the Company, and, in addition thereto, there will be outstanding approximately \$500,000 in bonds. Owing to the interest which the B. C. Copper Co. has bought in the new concern it will have due representation on the directing board when the permanent officers are elected. Only a temporary directorate is now in charge of the company's affairs. At Vancouver last week the court granted the application of B. W. Lincoln for an examination of the books of the Dominion Copper Co. It will be remembered that Mr. Lincoln represents the dissenters in the ranks of the Dominion Copper shareholders. One of the provincial accounting firms is at present working on the books at the Company's mines. It is largely a matter of legal opinion as to what the outcome of the claims of the dissenters will be, and by the time the re-organization and amalgamation with the B. C. Copper Co. is completed it will cost as much to get at the live interests through legal channels as it would to buy up a new lot of mines.

Since the B. C. Copper Co. resumed in the early part of

August the plant has produced about 600,000 lb. of blister copper. The company is holding about a million and a half pounds of copper in anticipation of better prices. Some of the local mining men, however, do not expect to see much of a rise in the price of copper for some time to come, as the surplus stock is not being lowered to any great extent, and there are many big producers on the Continent ready to double their capacity whenever the demand shall warrant.

Last week the B. C. Copper Co. acquired three more mineral claims in Kamloops camp: the Irene, Sunset and Shamrock. The management of this concern is wisely providing for the future needs of the company, and has some promising plans which will entail the enlarging of mining and smelting operations at no late date.

On the Enterprise claim of the group being operated by the Con. Mining & Smelting Co. of Canada, at Rossland, a body of ore was pierced by the diamond drill at 100 ft. from the surface. Drilling will be continued on this property for some time, before a more permanent form of work is undertaken. The Consolidated Co. shipped 3840 tons of ore to the Trail smelter from the Centre Star group during the week ending September 18.

It is now announced that the British Columbia Copper Co. will build another furnace, 56 in. by 30 ft., at its Greenwood smelter. This will necessitate enlarging the present smelter-equipment from 2000 to 3000 tons per day capacity. The Oro Denoro mine, of the B. C. Copper Co., was again started last week with a crew of about 25 men. It is anticipated that the Emma mine of the B. C. Copper Co. will also be working again in a short while. The Rawhide mine of the Dominion Copper Co. will be the first of the company's properties opened, and it is likely that work will be started there early in October. The reserve in the Rawhide and Idaho mines of the company is placed at between two and three million tons, that should average \$1 gold, 18c. silver, and 22 lb. copper per ton. This ought to give a net recovery of 17 lb. copper, and \$1.15 gold and silver per ton. To make a profit of 40 or 50c. per ton, it will be necessary to keep the mining charges down to about \$1.12 per ton; smelting, \$1.25; converting, refining, and marketing, 46c., which, after deducting gold and silver will give approximately 10½c. copper.

JOHANNESBURG, TRANSVAAL.

Air Compressor Accidents. — G. A. Denny and Recent Metallurgical Progress. — Bantjes Consolidated Mill. — Geldenhuis Amalgamation. — A Rand Snowstorm. — Mine for Training Purposes. — Sand-Filter Tables.

The question of air compression automatically increases in importance when labor grows scarce and more work has to be thrown upon machine-drills. It has recently gained prominence through other causes. Although a year or two ago explosions and combustions in compressor plants were hardly known, there has lately been a remarkable succession of accidents of this description, sometimes resulting in fatalities from the gas evolved. The most serious accident occurred at the Langlaagte Deep in March last, and a complaint was made by A. C. Whittome, past president of the Institute of Mechanical Engineers, at the last meeting of that society, that the Government engineers had not yet issued any report upon the cause of the explosion. It would be of great service to the profession if all cases were independently investigated by the mining department's officials and recommendations issued—if not regulations—as a guide to the users of compressors. There is probably need for greater control over these, and it is probable that many of the accidents are the outcome of carelessness, of overtaxing the plant while paying insufficient attention to draining off oil-accumulations, to the condition of pipe-joints, and to the suitability of the oils used. The purity of the air at the outlets is a matter for further investigation, quite apart from the extreme cases of actual explosion. Men working in development faces and in back stopes are so largely dependent on compressor-air that death may be a result of bad conditions quite as surely as when there is a sudden discharge of CO into the mine from the combustion

of gases in the plant or pipes. The Mines Department is doing very sound work in investigation, but as urged by many, their enquiry would be of greater utility if reports were issued with promptitude. It is unsatisfactory to think that they may be awaiting further accidents to provide the data necessary for safe conclusions. Let some recommendations be made, even if only provisional. In its direct bearing upon Rand practice, the question of putting in pre-coolers is now being keenly debated by mechanical engineers. Opinions as to their use are divergent. Pre-coolers have lately been adopted by a certain mine in East Rand and success is claimed. Experiments conducted by one of the Messrs. Eckstein's engineering staff indicated that while he was able to reduce the temperature of the air at the intake from 70 to 51°F., the efficiency of the inter-coolers was reduced, and the final temperature was even higher than when drawing air direct from the open. This anomaly was due to the humidity of the air after its passage through the type of pre-cooler used, which is declared by some to have been of unsuitable design. However, there certainly exists a weighty prejudice against pre-cooling, owing to the increased humidity, which not only is detrimental to inter-cooling efficiency, but is harmful to the parts of the compressor and increases the risk of freezing at the exhaust. It seems certain that Rand engineers would be grateful to their American confrères if they would publish their experiences with pre-coolers, and thus indicate upon what lines progress has been made in other fields.

In the MINING AND SCIENTIFIC PRESS of June 26, G. A. Denny writes to the effect that the results of the work done upon the Rand by himself and his brother go unnoticed, and that their detractors are parading as innovations the ideas they expressed years ago; also that "all that has been done metallurgically upon the Rand of any consequence" since 1906 was forestalled by them long ago in methods publicly described. Mr. Denny may or may not have had good cause to object to the article entitled 'Rand Milling Practice', which apparently roused him to protest, but he certainly is unjustified in making claims of so sweeping a character as those contained in his letter. Let Mr. Denny rest assured that the daring experimental work undertaken under his control is well appreciated today, and that the untiring thoroughness with which he pushed his investigations and propounded the results for the benefit of the profession must always be recognized as admirable and exemplary. Perhaps, however, Rand engineers would be more ready to express their indebtedness to Mr. Denny for the leading part he played in the introduction of tube-mills from Western Australia, if he had omitted to make such an assertion as "In 1905 we installed, in the face of universal local opposition, fine-grinding (in tube-mills), agitation with cyanide solution and filtering." To suggest that the tube-mills were "introduced" in the face of universal opposition is misleading. If Mr. Denny perceived symptoms of this "universal" antagonism, it must have been of a rather "stagey" description, seeing that his tube-mills at the New Goch (working on concentrate, not coarse sand) started work some days later than that erected by J. R. Williams and his associates, W. K. Betty and S. H. Pearce, at the Glen Deep; nor were the metallurgists of the firms blind to the oft-discussed effectiveness of fine-grinding, nor slow to realize the practicability of its accomplishment by tube-mills. As for filter-pressing, this practice has been abandoned. There is no tendency to return to it, although vacuum filtration has its supporters. Mr. Denny's indirect claim to be the pioneer of heavy-stamp practice is unfortunately unjust to those who, by years of experiment and observation, have been responsible for stimulating the process of evolution by which we have now arrived at stamps of 1700 to 1800 lb., and even greater weights. He writes, "The 1600-lb. stamps, of which so much is heard lately, were introduced by us on the Rand in 1904." The natural conclusion to be drawn from such a statement is erroneous. The Messrs. Denny erected a battery of five Morison high-speed stamps on the Meyer & Charlton, but (1) they were not found a success, and (2) by no stretch of reasoning can the experiments with that type of stamp be considered to have led to or to have suggested the gradual increase in weight of the

gravity-stamp to its present figure. In a place like the Rand, where ideas are exchanged with such freedom often long before they are put to practical test, it is commonly difficult to apportion credit with perfect impartiality, but it may at least be stated with confidence that the Consolidated Goldfields can claim credit for the earlier development of heavy-stamp practice on the Rand (while the Albu firm, advised by Mr. Denny, took an insignificant part), just as the Albu & Eskstein engineers were principally responsible for the introduction of tube-mills. All these remarks may appear personal, and could be more fairly discussed over a signature than in these necessarily anonymous columns. The matter would not have been dealt with at all, however, had not Mr. Denny written with what seems extravagant force, claiming to have been the pioneer of all metallurgical progress on the Rand and to be the victim of some kind of vicious persecution at the hands of his "one-time detractors." It is regrettable that he should have attempted to throw a discreditable light upon the work of his former friends and foes on the Rand (still speaking technically, for the attitude of financial heads has no bearing upon the points at issue), and that the principles governing the controversies in which he took so keen a part some years ago should have been neglected.

A great deal of importance has been rightly attached to the results of development in the Bantjes Consolidated, which is a large property in one of the least explored portions of the Rand. Work was re-started there last year and a small mill of 10,000 tons monthly capacity was erected. Results have clearly been satisfactory, for the plant is to be doubled forthwith, and this duplication is probably only a further step in the advance toward the larger-scale unit which should be the final aim in the expressed opinion of the consulting engineer. Another mine amalgamation, on a more modest scale than usual, is to be carried out in the near East Rand. The participating companies are the Geldenhuis Deep, Geldenhuis Estate, and Jumpers Deep, the first-named being the absorbing concern. The crushing capacity of the three mines is 74,000 tons daily, to be raised on amalgamation to 80,000 tons, and their joint ore reserves 2,122,000 tons, of an average value of 5.9 dwt. As compared with the Crown Mines, East Rand Proprietary, and Randfontein South, this is a small and low-grade combination. The Geldenhuis Estate has been a high-grade mine in its day, but it has lately been dealing with ore yielding only a little over \$5 per ton.

A few months ago it was my duty to record in these columns the unparalleled rainfall and floods in January, which were the cause of a heavy loss of life and money. The Rand has again been visited by what the writers in the daily press are proud to call an "unprecedented phenomenon." On August 24 there was experienced the first heavy snowstorm known for 19 years. About a foot of snow fell during the day. The consequent damage or inconvenience to the mines was not heavy, being principally witnessed in the breaking down of telephone lines and trees, and the temporary obstruction of some surface transportation lines. Had the snowstorm lasted longer, the results would have been serious owing to obstruction of the tailing-discharge service.

The Government, acting in co-operation with the Chamber of Mines, is still on the lookout for a 'State mine', suitable as a training school for miners. At the moment the possibilities of the old York mine at Krugersdorp are being investigated in this connection. This small property is being worked at present by Abe Bailey.

At the last meeting of the Chemical, Metallurgical & Mining Society, W. A. Caldecott read a paper on sand-filter tables, which he has successfully introduced at the Simmer Deep and elsewhere. A rough sketch of this plant, which is essentially a sand collector (producing a good granular leaching product) and not a slime-filter, as commonly understood, and erroneously given in the MINING AND SCIENTIFIC PRESS of July 10. Ample evidence has been brought forward to demonstrate the great saving in initial expenditure, as compared with the ordinary system of sand-collection in vats, the slightly better and more rapid extraction, the low current costs, and the practical reliability of the scheme.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Slime.

The Editor:

Sir—As an index of the general acceptance by metallurgists, of the value of 'sliming' gold and silver ores it is noted that Alfred James in his review of the progress of cyanidation for 1908, states that it was reported that some 5,000,000 tons of slime were treated by vacuum-filters during the year. It is but a very few years ago that slime was treated as a necessary nuisance to be disposed of as efficiently as possible, and efforts were largely directed toward seeking means to secure the crushing of ore in such a manner as to produce a minimum of slime, but the realization of the fact that in many ores the gold and silver were in an exceedingly fine state of division, and that fine grinding liberated more completely the minute particles in a form particularly suited to the action of the cyanide solution, led to a large adoption of the 'sliming' treatment, converting what had been heretofore an undesirable by-product into the chief form of output. The transformation of method was greatly stimulated by the means that were developed both for producing slime and handling it, the former aiding materially in the attack of the solution on the metal-content of the ore.

In crushing rock it is broken into fragments of varying sizes down to impalpable powder which settles but slowly, even in still air. Both the physical and chemical characteristics are usually complex, and it seems, so far as results are concerned, that an exact definition of the term 'slime' is not necessary beyond a determination of its susceptibility to ready treatment by the solution. Usually this fine product in any considerable mass is impermeable, and hence should be treated in detail, so to speak, in a manner so that each particle may be brought into sufficient contact with the solution. This is brought about in present practice by agitation in tanks provided with means for mechanical or air agitation, requiring a number of hours for the purpose, and afterwards allowing a partial settlement to take place, following by the decantation of a portion of the solution before turning the pulp into the filters, all of which requires a large tank-capacity and the consumption of much time.

There is probably no better condition in which the pulp could be placed after it has left the tube-mill, or other pulverizing machine, for the extraction of the metals than its course through the launders, where, in a comparatively thin stream, it is subject to agitation, aeration, and the attrition of the particles against each other and the launder, all aiding in the solution of the metal. It is worthy of consideration whether a sufficient extension of the launder system, aided by some pumping facilities to supply defects in fall, might not be an economy in space, time, and tank-equipment, and produce better results. It is interesting to note, in this connection,

that in the method recently introduced in the Simmer Deep and the Jupiter joint mill in the Transvaal, as briefly described in the MINING AND SCIENTIFIC PRESS of July 10 last, the de-watered sand which is washed by a 0.3% solution from the filter-tables to the collector vats has 50% of its gold dissolved in the passage.

Two general types of vacuum-filter have been developed for the purpose of handling the slime after the extraction has been completed, although there are many varieties of these. One of them is dependent upon the accumulation on the filter surface of a cake of the solid portion of the pulp by means of suction in opposition to gravity, and the final disposition of the cake by dropping it through the medium of gravity, assisted by a reversal of the pressure previously applied, and by more or less scraping. In this type the homogeneous character of the cake is an element of great importance, for on it depends the successful washing, and great care is necessary in transferring from the pulp to the wash-water so that the cake be not too much dried, which tends to produce cracking, thus reducing the efficiency of the washing. While in this type of filter it is possible to present a very large filter-surface in a small floor-space, great care is necessary in the accumulation of the cake, which accumulation seems to be facilitated by the use of a thickened pulp in which any tendency to the settlement of the heavier solids is retarded by the thickened condition of the mass, otherwise, in the height of the leaves of the filter, there would be a decided difference in the density of the cake at the top and bottom. An interesting difference appears to exist between the basket-type of filter and the Ridgway form, consisting of the small horizontal filter-frame which is dipped first into the pulp, and which rapidly accumulates a cake about $\frac{3}{8}$ in. thick, then automatically dips the cake into the wash-water and afterwards dumps it by a reversal of pressure. The basket-filter exposes from 50 to 75 sq. ft. of surface per ton of daily capacity, while the surface of the Ridgway exposes from 1 to 2 sq. ft. The former receives its charge of 1 in. in 30 to 60 minutes; the latter accumulates $\frac{3}{8}$ in. in 13 seconds; or assuming the 50 ft. exposure and the 30 minutes time in the one case, and the 1 ft. exposure and the 13 seconds time in the other, this would result in 144 cu. in. per square foot in 30 minutes in the one case, and 7452 cu. in. in the same time in the other. These figures are not cited as absolutely representing the relative merits of the two forms of filter, although such have been reported as their accomplishments. They serve to indicate, however, a great difference in point of time in the accumulation of a thick and thin cake under the respective conditions, and further point to a possible advantage in the attack in detail instead of in masses. The basket type of filter might be denominated 'the adhesion type', from the method of accumulation and of holding the cake as distinguished from the other type to which I have referred, in which the accumulation of the cake is accomplished by a vacuum, aided by gravity, and its final disposal by mechanical means. In the latter type the thickness and uniformity of the cake are not matters of

such prime importance: the chief aim is the separation of the filtered solution from the solids, in the accomplishment of which there is a vastly greater latitude with respect to the condition of the cake than in the former, in which the homogeneity of the cake is an essential to the successful operation.

This type embraces the horizontally revolving filters, and differs in principle from the other mainly in the reversal of the application of the force of gravity. It might be denominated as the 'upright' or direct method of filtering in contra-distinction to the 'adhesion' system. By dealing with smaller quantities at a time, and presenting cleaned surfaces to the pulp, it participates in the advantages of the attack in detail, if such there be. It results in a very simple device, automatic in operation, and in which the cake is in full view at all times; it is equally applicable to coarse or fine material or both together; in fact, in particularly impermeable material the addition of sand would considerably aid the filtration; nor does the particular character of the cake injuriously affect the washing which is not accomplished by flooding or submersion. Just sufficient water is used to thoroughly wash out the remaining valuable solution, all of which is retained, and there is no liability to loss from osmosis. The wash-water is applied uniformly over the cake in small quantities, and is drawn through at the point of its application and may be applied at different points of the cycle in such a number of successive applications as may be desirable. With the numerous successful means of handling slime, the two general types of which I have endeavored to briefly review here in so far as they include the vacuum-filters, the early slime bug-bear to the cyanide man has been quite thoroughly eliminated, and the problem has been relegated to the pulverizing-device for determination as to how far the fine-grinding may be profitably carried.

EDWARD PARRISH.

Newport, Rhode Island, September 21.

Continuous Sand-Filters.

The Editor:

Sir—In your issue of July 10 you refer to a continuous revolving filter for slime as being applied to the Rand mills by W. A. Caldecott, the same being introduced into American practice by Bertram Hunt a year ago. In justice to Mr. Caldecott I wish to point out that his device is a sand-filter and not a slime-filter. Mr. Caldecott had a 10 ft. diam. sand-filter running successfully at the Knights Deep, Limited, in the early part of 1907, before he visited the United States, and a year before Mr. Hunt's filter started.

Though a correct description and photograph are given on p. 48 of the MINING AND SCIENTIFIC PRESS of July 10, you were doubtless misled by the fact that many slime-filters exist, while, so far as I am aware, Mr. Caldecott's filters are the only existing sand-filters with continuous discharge in regular use, their introduction being a new departure in metallurgical practice. The development to date of the rotary vacuum sand-filter tables, and the extent to which they are now in regular use is fully described

in a paper read before the Chemical, Metallurgical and Mining Society of South Africa, on August 21, 1909. All the sand produced by the Simmer Deep, Ltd., stamp-mill, which crushed last month 75,000 tons of ore, has been continuously and satisfactorily handled for several months by two 20-ft. sand-filters, and a great saving has thus been effected in the number of sand-vats otherwise required. I hope you will correct the impression your editorial has given.

Excess Ground in Mining Claims.

The Editor:

Sir—In the issue of the MINING AND SCIENTIFIC PRESS of September 25, 1909, at the bottom of the first column, page 425, is the following item: "A mining location which exceeds the maximum limit is void only as to the excess, unless fraud is shown. The locator has the right of selection of the ground to be retained, even as against an overlapping locator."

The first sentence states the law as it is. The second sentence may not be the true rule. I do not care to trouble you, but if you have the authority for the second sentence handy, I would like to have it. This very question was in issue recently in a trial in Goldfield, and my recollection is that Judge Stevens held the other way, namely, that the locator in casting off the excess must be guided by the middle line of his claim, one determining point of which is his location monument, or his point of discovery. I refer here, of course, to an excess in width; the rule is correct as to an excess in length.

MARK R. AVERILL.

Tonopah, Nevada, September 28.

[The item you refer to is correct as the statement of a general rule, but like all condensed and categorical statements of a similar character, is subject to qualification. It was intended to include both placer and lode claims. Of course, it is unnecessary to state that the locator of an excessive location could not elect to cast off a vital part of his claim, such as his discovery, or his discovery shaft where the latter is required by State law, without running the risk of invalidating his entire claim. Nor could a lode locator safely exclude from his claim such an essential part of the claim as the apex of his discovery vein nor could he include territory which the law would not authorize in the first instance. The point you raise about casting off or retaining an excessive width should be determined by the general test—would it have been lawful in the first instance to have included that particular piece of territory in the location?—if so, the locator of the excessive location may usually elect to retain it, otherwise he may not. For example, if a locator staked out a claim of excessive width with 350 ft. on one side of his lode and 300 ft. on the other, he could not elect from which side he would cast off the excessive width, for it was not lawful for him to have included more than 300 ft. on either side of his lode in the first instance. This question of excessive width of a lode location is admirably treated by Costigan in his recent work on Mining Law, pp. 199-204.—EDITOR].

THE MONTEREY FLOOD AND SAN LUISITO BRIDGE.

Written for the MINING AND SCIENTIFIC PRESS
By SAMUEL J. LEWIS.

During the night of August 27 last, a disastrous flood occurred in the Santa Catarina river in the State of Nuevo Leon, Mexico. The city chiefly affected is Monterey, which has a population of about 85,000. Not less than 3000 persons were drowned in the city alone, exclusive of the heavy death-toll lower down the river: the property-loss runs into the millions. Benito Juarez street, the principal north and south thoroughfare, crosses the river at right angles at the south side of the city, the district on the other side of the river being known as the Barrio San Luisito, and the bridge as the San Luisito bridge. This structure was completed in 1908. It is of reinforced concrete throughout; and consists of a covered foot and cartway, flanked on both sides by small shops. It is supported on three piers: one in

measurements with floats on September 8, flowing about 900 cu. ft. per second.

On arriving at the bridge, which by its shape and small clearance for water practically dammed the channel except for very small flows, the velocity of the flood was temporarily checked, causing rapid deposit of sand and gravel brought down by the torrent. The extent of this deposition may be studied by comparing the illustrations. The 'wash' practically filled the old channel. The ground at the left in Fig. 2 is the San Luisito district, the view looking west toward Mitra mountain in the distance. The other view, Fig. 3, shows the bridge today, with the space between the piers completely filled with gravel above the spring of the arches. This deposition must have occurred very fast, as the waters, arrested by the solid bulk of the bridge, piled themselves up against it to a frightful height, the arches merely acting as culverts of rapidly diminishing cross-section. Only under high velocity could the river move such heavy gravel, and the moment the reduction in

velocity took place, the gravel had to come down. Under the terrific pressure, the water coming through the arches carried a heavy load of gravel down stream for some 200 ft. below the bridge. Meanwhile, however, as the pressure against the structure increased, one of two things had to happen; either the bridge had to go, or the river had to find itself a new channel. The latter it had begun to do under the same conditions on August 10 during the severe storm of that date, when a destructive body of water came down river in what was then spoken of as a great flood. On the present occasion, with the bridge well and solidly

Fig. 1. Map of Monterey District.

the centre of what was then the channel: the other two at the abutments. This gives two 70-ft. spans, springing in low flat arches, about 7 ft. high at the crown. The height from the river bed to the spring of the arches was about 7 ft. also. Reference to the illustrations will make clear the form of the structure. It is only necessary to add that both sides of the stream were thickly built up as far down into the bed of the water-course as individual opinion thought consistent with safety. It should be remembered, also, that this stream is absolutely dry for 350 days in the year, nine years out of ten.

Twelve hours before the storm the river was dry; as the rain continued Friday evening, the water began to rise rapidly, the heavy storm of August 10 having brought the water-table up close to the surface. At about 9 o'clock in the evening of August 27, apparently in a brief interval, the water arrived at the upper limits of the city, running breast-high, at high velocity, and sweeping all before it. The maximum then attained was kept up with but slight fluctuations until a little after 9 o'clock the next morning. It then began to fall, and was, by my

tied to three reinforced concrete piers sunk 25 ft. below the old surface of the gravel, the energy developed proved inadequate to move it. The river presently tore out the soil at the north end, taking part of the abutment with it. On account of the ground being high on that side, however, but little of the water could get away. At the south end, the only high ground was that at the abutment, partly built up, to meet the grade-line of the bridge; the rest was low, gently sloping up from the channel. The mass of water, unable to get past the bridge, cut its way through the soft soil at the south end; the abutment walls were of re-inforced concrete about 2 ft. thick, built with smooth rods, and the ends not upset, nor with any other provision against slipping. The rest of the abutment was 'dry-fill' of heavy gravel from the river bed. As the soil was cut out, taking with it some of this loose fill, the abutment walls had to take the full strain, and failed by the pulling out of the rods. This is shown in Fig 4, where the rods are seen to have come out clean. The abutment became a total wreck, everything giving way right up to the pier, where the arch is tied

in. The arches themselves were not seriously damaged, beyond cracking along the top throughout their whole length. The superstructure was punched full of holes by drift-wood, which filled the interior.

The foregoing description of the bare facts shows that the discharge-area of the arches was not adequate to carry off even a small fraction of the flood-

from this that the question of how much the stream might have to carry off could not have entered into the design of the bridge.

A study of the drainage area of the stream, as shown by the map, Fig. 1, reveals that the Santa Catarina drains approximately two million acres above Monterey. The map, copied from the excellent official production prepared under the direction of the Governor of the State, Bernardo Reyes, shows a rugged mountain country in which the main canyon seldom exceeds a mile in width, with innumerable tributary gulches of much narrower channel. The main river valley is almost solidly walled in by mountains, which, in a mile or two of horizontal distance seldom rise less than 3000 ft. to the crest, and frequently more; all this being absolutely bare limestone rock. The only soil and vegetation, capable of retaining water, are found in the bottoms, and such

Fig. 2 & 3. San Luisito Bridge. During Construction and After Flood.

flow that might reasonably be expected in a stream of this character, and it is my opinion that a large proportion of the damage and loss of life was directly due to the presence of the structure in the river bed. Had the channel been clear, the waters would probably have caused destruction on both sides to a

Fig. 4. Rods Drawn From Concrete Abutment.

ground is probably less than 10% of the total area. As to the grade from Monterey to the Obispado, a distance of over a mile, it averages 1%; from there to the village of Santa Catarina, 1½%; from there to Nogales, 3; and from that point on up the canyon the grade gets steeper to the various crests of the di-

vides. With the soil bearing so small a proportion to the total area, and well soaked up from previous rains; with every feature of the topography favoring very rapid run-off, it seems clear that a maximum proportion of the total precipitation, amounting to not less than 50%, and probably to much more, should be expected to arrive at the bridge site in a brief period. The foregoing facts as to the coming of the flood show that the maximum remained constant for 12 hours. Now, official and private observations of the precipitation of August 27 coincide in

Fig. 5. Santa Catarina River at Monterey in Flood.

greater or less extent as it rose, but the grade is so steep in the water-course that very large bodies of water would be rapidly carried off. With the banking up of the stream some 10 ft. higher than the piers, the whole valley for more than a half mile up-stream has filled, encroaching on ground that otherwise would have remained unharmed. It will be clear

making it 22 in., of which about 15 fell during the 12 hours of flood. If the rainfall be taken as 1 inch per hour, and 50% of the precipitation over the whole area be assumed as arriving at any stated moment during the flood, there results one inch over two million acres, or roughly, 150,000 acre-feet of discharge; of which 50% gives 75,000 acre-feet per

hour, or 20 acre-feet per second; this means about 800,000 cu. ft. per second. If even 10% of this quantity, or 80,000 cu. ft. per second, could by any possibility reach the bridge at one time, it should obviously be so designed as to carry off the whole of the discharge with a minimum of obstruction. The velocity of the surface of the stream during the flood was estimated by experienced engineers to be about 30 ft. per second. As the velocity of the comparatively insignificant thread of water now remaining is 7 ft. per second, this estimate seems not unreasonable. Taking the measurements above given of the bridge clearance, two areas 70 by 7 ft. are obtained, and two areas each $\frac{2}{3}$ (70×7); a total of 1632 sq. ft. At a velocity of 30 ft. per second at the surface, the available channel under favorable conditions could carry 49,000 cu. ft. per second. Comparison of these figures with the possibilities of the drainage area show at once how totally inadequate such a channel must have been. Doubtless a thorough study of the topography might modify these statements to some extent, but even from the foregoing hastily prepared data it is clear that the design of this bridge did not take into account to any appreciable extent the drainage problem of which it should have been the solution. Even the angle the structure makes with the current is such as to favor deposition. If it had been a right angle, there might have been a possibility of scouring with the velocity developed, which, perhaps, would have helped; with the 15 degrees or so of deflection, the conditions were most favorable for deposition of material carried in suspension. Finally, if any reader be skeptical as to the enormous discrepancy between the figures above developed and the actual capacity of the bridge, his attention is invited to the illustration, Fig. 5. This shows the river at flood, with the bridge barely distinguishable at the right of the picture. The fact speaks for itself.

From an engineering point of view, it is not of great importance that this storm was of most unusual severity; the important thing in design would be that the drainage area served by the river is capable, because of its extent, of receiving easily calculated quantities of rainfall, and of delivering them past a certain point at calculable intervals of time. These points should have been the first determined in the design of the structure, and failing satisfactory information on that score, the ethics of engineering would seem to indicate refusal to do the work. As it was, the thing was a purely commercial proposition, worked out without the supervision of a hydraulic engineer, and the results were disastrous.

Copper ore shows an increase in imports of nearly 50%, 36½ million pounds having been imported in the seven months of 1909, against 25½ millions in the same months of 1908; and copper pigs, ingots, etc., show an increase of 96%, 138¾ million pounds having been imported in the seven months of 1909, against 71 millions in the same months of last year.

Imports of pig tin show an increase of nearly 25% during the current year, the quantity imported in the 7 months ending with July being 56 million pounds, against 45½ millions in the corresponding period of 1908.

UNDERGROUND WATERS IN SEMI-ARID REGIONS.

By W. C. MENDENHALL.

*Many gravel-filled valleys west of the Rocky Mountains contain both surface and underground waters, not enough of either alone to irrigate all of the tillable lands, but when both are used together are much more valuable than when either is used alone. Often power can be developed upon surface streams and this power applied to the recovery of the earth-waters that saturate the lower valley-lands. This mountain water coming down to the lands from above is made to lift the underground water to the lands from below; a most admirable combination, and one excellently illustrated in the case of the Santa Ana river in southern California. A part of the water of this river is stored in a reservoir in the San Bernardino mountains, and the flow of the stream thereby regulated. After it escapes from the reservoir it is diverted through a power-plant and electric power is generated. Below the first power-plant it is re-diverted and passed through a second power-plant. Below this it is all distributed and used for municipal and irrigation purposes about Redlands and Highlands. The waters that return from the irrigation are recovered in springs and flowing wells and by pumping plants, a portion of the power developed higher up on the stream being used for the latter purpose. This recovered water is used for irrigation about San Bernardino and Riverside. A part of it re-appears in the river above Riverside Narrows, where it is again taken out into a power-ditch, the waters being returned to the river above Corona. A few miles below it is picked up by canals and distributed to the orange and deciduous groves about Anaheim and Santa Ana. The portion of it that returns there, by irrigation, to the ground-water is once more recovered by the many pumping plants and flowing wells west of Santa Ana in the lower coastal plain. A single drop of water in its progress from the mountains to the sea, a distance of only 100 miles, may thus be used as many as eight times for power and irrigation. This is an almost ideal use of water. The combination of power-development and the recovery of underground waters to supplement the surface-flow results in a minimum of waste and a maximum of economy. Development of this type is being rapidly extended now over parts of the West and will receive still further extension in the future. But care must always be taken not to tax too severely the underground basins from which the water is drawn. They are not by any means inexhaustible. When rainfall is light, the quantity of water returned to the reservoir each year may be small, although the quantity stored there is large. However large it may be, if more is withdrawn each year than is replaced, there will be a gradual lowering of the ground-water level and ultimate disaster. Therefore, users of ground-waters in arid regions must study carefully the effects of development in order to be sure that they are not prospering during the present at the expense of disaster in the future. Furthermore, in many sections where water is badly needed ground-waters do not exist.

*Abstract from U. S. Geol. Surv. Water-Supply Paper 234.

MINE INSPECTION.

By COURTENAY DE KALB.

*Mine inspection in the United States has been generally neglected except where the dangers of coal mining have forced legislatures to devote attention to proper police regulation. The tendency is always strong to avoid Governmental interference with private enterprise and the influence of mine owners has usually been stronger than that of the mine operatives, hence small headway has been made in providing protective measures. Moreover our peculiar form of government has rendered such action more difficult. Mine regulation in foreign countries is established by the central government but the Congress of the United States has no power to enact police regulations which shall apply to the separate States. Under such conditions it is more difficult to arouse public sentiment favoring measures which limit the freedom of individuals. The growth of the mining industry, however, by increasing the number of laborers employed in such operations, has aroused interest in this matter to a degree formerly unknown. The result has been the passage of Acts by several States, the chief characteristic of which has been their inadequacy and their dissimilarity. It is of great importance that uniformity in mine inspection should exist, in order that our shifting population of miners and mine owners may always be familiar with the regulations to which they must conform, otherwise confusion will result, and errors which may prove fraught with peril will necessarily be made by those having the lives of their fellow men under their charge. The passage of laws for police regulation of mines by separate States should be discouraged at the present moment until some means has been found for bringing about co-operation between them in the enactment of similar statutes. Conditions may necessitate variation in minor matters, but with regard to mechanical matters which are common to all mines, and upon which safety to operatives so largely depends, there should be no divergence. It would seem desirable to take such steps as will lead to the enactment of a Federal statute which should be based upon such careful study of conditions at home and abroad as would serve as a safe model for all States to follow. A Federal statute would, of course, apply to the territories and to Alaska. By this means the United States Government, without interfering with State sovereignty, can blaze the way and render a permanent service to the country at large. The purpose of mine inspection should be strictly and solely that of police regulation, the object of which must necessarily be the preservation of life, health and property. An essential feature of any police regulation is that it shall apply as a universal principle, and not in any respect discriminate between classes and industries. A regulation may be made to apply to a specific industry where the purpose is to assure protection which is the prerogative of the commonwealth, and which requires def-

inition for application under the specific circumstances presented by special callings. Theoretically there must always be a *quid pro quo*, a mutual benefit accruing to both the specific persons involved and the commonwealth, in order to insure validity. To particularize would carry me beyond the scope of the present discussion. The hint is thrown out merely to show how readily excess of zeal may sweep legislatures into the enactment of unconstitutional measures.

Mine inspection should concern itself essentially with the concrete; with the mechanical, considered in its broadest sense; and not with relations between capital and labor. Those questions should be reached by other routes, because they involve questions which necessarily must be determined by judicial process and which cannot properly be submitted to the summary action which is usually conceded as a necessary part of the powers conferred upon a mine inspector. Insistence must be made upon the necessity of reciprocal benefits between operator and operative in the regulations for mine inspection. What benefits the laborer should benefit the property, and vice versa. The basis of legislation is ultimate economy and not theoretic altruism. The case for economy can easily be made out when it comes to legislation for mines. No one desires the loss of human life; this for humane reasons as well as for economic, and that which endangers life is always more productive of injuries which merely cripple men and from the standpoint of mine operators this is costly and is becoming more so since the responsibility of employers in this regard is becoming more sharply defined by law. There is apt to be, however, indifference to the health of employees and it is difficult to convince employers that removal of unhealthful conditions necessarily involves greater efficiency of labor.

Another advantage of judicious mine regulation is found in the better maintenance of equipment. It tends towards standardization, which is also economical. It demands attention to detail, which makes for efficiency and reduction in cost. Although home-made appliances may be impossible in compliance with the law, the end is to improve conditions for profitable production.

Mine inspection should be placed completely beyond the power of inspectors to display favoritism, under which is veiled the possibility of graft. The only safeguard against subversion of inspection to unworthy ends is to make the regulations specific and mandatory. Discretionary power must be allowed to a certain extent, but this should be as circumscribed as possible. The summary powers of a mine inspector should be limited to as few cases as may be permissible for the proper execution of the act and in all cases where immediate danger to human life is not involved recourse to regular judicial process should be required. There are few powers which can be conferred upon a layman so dangerous as judicial functions. It is clearly unwise to invest mine inspectors with advisory powers. The danger from so doing lies in the excuses which could be offered to exculpate themselves from blame by corporations and individuals who had acted under ad-

*Address presented at the American Mining Congress, Goldfield, Nevada, September 29.

vice which the law had not contemplated in its specific definitions of authority.

The character and qualifications of mine inspectors is a matter of serious import. This is one of the questions which need not of necessity be uniform throughout the country. It is a question regarding which differences of opinion can probably do no serious harm. As a matter of opinion, I venture to affirm that well-trained men who are competent to assume the responsibility of mine foremen, generally make the best inspectors. The tendency is growing to require mine foremen to pass examinations and obtain certificates in the same way as the law requires for engineers. This will insure a higher grade of intelligence and a knowledge of technical methods superior to that generally possessed by mine foremen today, and which would be adequate for the purpose of administering the law. Selections made from such a class will insure a knowledge of minute detail which is of the highest importance.

The subject matter of mine regulations will involve many points. The conditions affecting surface plant should follow in the main such regulations as apply to factory inspection. There is no essential difference between conditions leading to safety in factories and in the surface plant of mines and smelters. The conditions met with underground, however, are extremely special in their nature. The dangers of traffic in shafts are well known. They require inspection of track and guides; inspection of cages and skips; detailed inspection of cables and safety devices; constant inspection of spots where weakness is known to exist; inspection of loading-pockets to prevent the possibility of accidents from falling rock and ore; inspection of the signal system, and finally, absolute uniformity throughout the country, of mine signals. Lack of uniformity in the signal system is peculiarly dangerous, and yet not even so simple a matter as requiring one bell to start, and one bell to stop when in motion, has become universally adopted. Montana has made the greatest advance in an attempt to elaborate a signal system, but even that is not well enough perfected to insure freedom from confusion of signals. Drainage problems, likewise, require careful regulation. This involves proper grade for levels, thereby promoting healthful conditions underground; and inspection of pumping equipment and investigation of the relation which the capacity of such equipment bears to the quantity of water actually to be handled daily, in order to insure an ample margin of safety in case of sudden accessions. Ventilation in metal mines has to do wholly with health; in coal mines it has to do also with protection of life from explosion. The conditions found in coal mines are so unlike those of metal mines that regulations applying to one could not justly be made to apply to the other. In fact the peculiarities of coal mining require a set of regulations especially designed to meet them, and it can hardly be expected that the same inspector could serve for both. A sharp distinction should be drawn between the police regulation of coal mines and metal mines.

Sanitation is a matter which receives great attention abroad, but has been generally ignored in

America. There is no doubt that mines are frequent breeding-places for tuberculosis, typhoid, diphtheria and other germ diseases. The contamination of waters underground by seepage from the surface is a common cause of peril and has been recognized by foreign regulations. Provision for ample exits in proportion to the size of a mine and the number of workmen employed, is another matter which requires to be carefully regulated. The growing use of electricity under high tension in mines necessitates provision for safety both in regard to the lives of workmen and the possibility of fire. To a certain extent the methods of mining employed may be subject to inspection and discretionary regulation for the protection of human life. This is a matter of grave import; one in which a careless or prejudiced inspector might easily subject mine owners to inconvenience and financial loss, and cases are constantly arising where chances are being taken that are wholly unwarrantable. Summary action may be necessary on the part of an inspector where peril is imminent but in such cases provision should be made for immediate determination by a competent committee to prevent the continuance of an unjust injunction against operation. It is a matter in which regulation is necessary, but in which the interests of operators should be guarded with extremest care. Authority to close old workings is necessarily one of the legitimate functions of a mine inspector in all cases where peril may otherwise exist. Reports of mine inspectors can easily be made the subject of abuse. It seems unwise to combine the function of mine inspector with that of conveyor of information to the public. The publication of data concerning the extent of workings and of geological conditions should be eliminated from an office which essentially pertains to the police.

I said in the beginning that mine inspection in foreign countries has been carried to a higher pitch of excellence than is comprehended here. It is manifestly desirable in consequence of this that we should inform ourselves concerning those systems before undertaking to create one for ourselves. Sometime ago the Technological Division of the United States Geological Survey invited a number of gentlemen identified with mine regulation in the European countries to visit the United States as the guests of this Government. They were taken through the principal coal fields and inspected our mines. The result of their criticisms was to awaken the public to a realization of the backwardness of our own legislation and to the need of a forward movement. This was followed by the sending of George S. Rice, mining engineer, Clarence Hall, explosive expert, and J. W. Paul, formerly mine inspector of West Virginia, to Europe to investigate coal mine regulations. This is a step in the right direction. It should be followed by similar investigation of regulations affecting metal mines, and it would seem desirable that more than a single individual should be sent for this purpose. We need not only the collection of data by an individual, but the value of the point of view of different intellects. As a preliminary, it might be advisable to obtain data by requiring special reports from our consuls

INSPECTION OF MINES.

Written for the MINING AND SCIENTIFIC PRESS
By J. A. HOLMES.

*Mine inspection is and should remain a function of the State. It has for its purpose the proper execution of State mining laws; and the object of these laws is primarily the safety of the miners, incidentally the protection of mine property. The agent of the State in the carrying out of these laws is the inspector of mines, and his assistants. These should be sufficient in number for frequent and thorough inspection; the basis for selection and continuance in office should be fitness for office, efficient service, and good behavior. They should be independent of political or other extraneous influences. They should receive compensation for services commensurate with the responsibility resting upon them, and the experience and technical training required. They should have reasonable laws to execute. They should have the willing co-operation of both operators and miners in carrying out the provisions of the law. Under such conditions men of the best type will accept and hold these positions, and their actions will receive the support of public opinion and of the courts.

This inspection by officers of the State, whenever practicable, should be supplemented by the work of special inspectors employed by the mining companies. Many companies have already adopted such a practice and report favorable results. In other coal mining countries this practice has become much more general, but in recommending to American coal operators the adoption of practices found successful in other countries it should be remembered that the selling price of coal at the mines in the United States is less than half that in other countries; and this fact may render impossible here many improvements in behalf of safety and efficiency which the American operator would otherwise be glad to inaugurate.

The function of the Federal Government in connection with mine operations is one of inquiry and research, having in view two fundamental purposes: (1) greater safety for the lives of miners; and (2) the conservation of mineral resources.

In connection with ordinary mine inspection the special service rendered by these investigations will be: (a) the development of data such as will serve as a basis for the enactment of reasonable laws, rules, and regulations; (b) the establishment of facts which may serve as a basis for the settlement of disputes between inspectors and operators or operators and miners, either by the courts or boards of arbitration.

The propriety of having such inquiries and researches conducted by the Federal Government in relation to mining, will scarcely now be questioned in view of the fact that such policy has long since been accepted in relation to agriculture, forestry, fisheries, and other industries, but it may be added that the practice avoids extensive duplication of labor and expense by the States. The Federal in-

vestigations naturally cover a wider field of experience, including also experience in other countries; and the results are likely to be more generally accepted as impartial, being further removed from local influences.

Under such an arrangement there will be no basis of conflict between the State and Federal interests; no encroachment of one on the duties or rights of the other. The support of the Federal work will depend upon its securing and maintaining the good-will and co-operation of the State's inspectors; and the success of both the State and Federal work will depend upon their securing the proper friendly co-operation of the miners and operators. Nor is anyone now likely to question the proposition that the conservation of resources is a national as well as a State problem. In the mining, treatment, and use of mineral products, no State boundaries are involved. An ore mined in one State may be milled in another, smelted in a third, refined in a fourth, and used in many different States. The coal mined in Pennsylvania or in West Virginia may serve as a basis of heat, light, power, and various manufactures in a dozen or more different States, and may be essential to the interstate transportation of mails, passengers, and freight; while the manufactured products to be transported may in turn serve as an essential basis for other industries in the remotest parts of the countries. The iron ore of Minnesota, may in Illinois be mixed with coke from Pennsylvania, and limestone from Indiana, to be fabricated into steel to serve as frames for buildings in San Francisco, or New Orleans, or Boston, or as railway bridges across the Columbia, the Mississippi, the Hudson, or the Nile.

The products of the mine constitute no less than 65% of the total freight-traffic of the country; they are indispensable to inter-state and international commerce; and are essential to both present and future welfare and to greatness as a nation. It is believed that the development of a system of co-operation between the Federal and State authorities such as is thus outlined, will contribute to the improvement of the service by both the State and Federal Government; will safeguard the rights of the States; will give greater uniformity to mining law and rules in the different States; and will be generally helpful to the mining industries of the country.

MINERAL AREAS IN KOREA.

Korean Government authorities place the number of localities in Korea suitable for mining at 184, including gold, silver, copper, iron, lead, graphite, zinc, coal, petroleum, and mercury. Aside from seven gold mines, two copper properties, a number of iron prospects, two or three graphite mines and a couple of coal deposits, the mineral resources of the kingdom are undeveloped, and as yet, largely unproductive. A number of claims have been filed but the holders of mineral areas in Korea are, as a rule, unprepared in a financial sense to do development work. Korea, therefore, offers opportunities for those desiring to investigate mineral deposits with a view to investing should expert examination prove satisfactory. Of 438 concessions granted, 107 are for placer mines.

PETROLEUM IN BURMA.

By E. A. WAKEFIELD.

*While the oilfields of Burma have been worked since the middle of the eighteenth century, it is only since 1889 that the industry has been operated with modern appliances and in a business like manner. Prior to that date the work was carried on spasmodically by the Burmese hereditary oil diggers. The richest oil-bearing tract of Burma lies in the valley of the Irrawaddy, in upper Burma, in the southern portion of the dry zone. Considerable oil is still obtained from wells dug by native labor, but the principal output is from wells regularly drilled with modern machinery. The output of the hereditary well lessees is purchased by the refining companies at varying prices. A royalty is paid to the Government of 16c per 100 viss (365 lb.) in the case of early leases, and 16c. per 40 gal. in later ones. A system of pipe-lines has been installed. The first section was about 45 miles in length, connecting the fields at Singu and Yenangyat with Yenangyaung, and pumping stations were installed at Singu and Yenangyat. About the same time another line was constructed to convey the oil from the tank-boats to the refineries. As both these lines were operated successfully, the construction of a pipe-line from Yenangyaun to Rangoon, a distance of 275 miles, was begun early in 1907. This line is now completed and will materially lessen the cost of transporting oil from the fields to the refineries. There are four pumping stations on this line, each connected with Yenangyaun and Rangoon by telegraph.

Oil is also produced in the districts of Kyankpyu, Akyab, and Thayetmyo. Prospecting is continually going on, and there is no doubt that there are many valuable fields as yet undiscovered or undeveloped. From the Cheduba wells, in the Kyankpyu district, a thick dark-colored oil is obtained which is used for burning, for covering the bottom of boats, and as wood varnish. The amount obtained from these wells is, however, quite insignificant. The methods used in obtaining this oil are primitive and wasteful. The earth is turned up to a depth of 2 ft. over a surface of about 20 sq. yd., around which a bank of soil is raised, forming during the rains a shallow pond. The oil rising to the surface of this pond is skimmed, scooped up with cocoanut shells, and placed in earthen pots. This operation takes place at day-break, when the temperature is lowest, as during the heat of the day it is nearly or quite impossible to separate the oil from the water. In the months of March and April these ponds gradually dry up, and the bottom of the pond is again dug up and prepared as in the first instance. The deeper the pond is dug the greater the season's product.

Some of the native hereditary oil reserves are of considerable importance, but as they are usually worked in the most primitive manner the yield is small compared with the output of the English firms, and there is always the danger that the methods of extraction may reduce the permanent output. Two of these native reserves are of decided importance,

the Twingone, about 300 acres in extent, and the Beme, containing about 160 acres. The number of private wells and well-sites in these two reserves is now over 3700. Of this number, however, some 1500 have been temporarily taken over by the Government for non-observance of regulations.

At present the best known and developed field is at Yenangyaun, the average daily output being about 15,000 viss (54,750 lb.). There are other newer fields being developed, which are producing oil in constantly increasing quantities, notably the ones previously mentioned at Singu and Yenangyat. In Singu township oil was first struck October 30, 1901, and the output has been steadily increasing since that date. The oil produced from these wells has an extraordinarily low flashing point (below 40°F.), while the specific gravity of the oil is 0.8247. At the present time nine companies are engaged in the extraction or refining of petroleum, with a combined capital of \$22,700,000. The value of the unrefined oil produced in 1901 was \$983,551, and in 1907, \$2,917,895. The output of the Burma oilfields is all disposed of in Burma or other provinces of India. For the three years from 1903-4 to 1905-6 a considerable amount of oil was exported, principally to the Far East. With the exception of that period, the oil dealers have confined themselves to the Indian market.

A considerable quantity of high-grade oil is imported into Burma, principally from the United States. In 1907-8 the imports amounted to 2,230,592 gal., valued at \$407,048, of which 2,188,442 gal., valued at \$396,693, were from the United States. Burma's trade in oil with different parts of India, excluding the trade of Rangoon and vicinity, in 1901-2 was 16,542,432 gal., valued at \$2,657,554; and in 1907-8, 69,464,772 gal., valued at \$7,218,390. The Burma Oil Co. has enlarged its refineries for the purpose of supplying fuel oil to the British admiralty, and it is expected that large shipments of this commodity will be made in the future. There are between 75 and 100 Americans engaged with the various companies, and the opportunity to increase the sales of American machinery should not be overlooked.

SAND-LIME BRICK.

The sand-lime brick industry is comparatively new in the United States, having had its beginning in Michigan City, Indiana, in 1901. Its progress was slow at first, the value of the production in 1903 being only \$155,040. From that time the value increased each year until 1907, when the maximum of \$1,225,769 was reached. In common with other building materials there was a decrease in 1908 in the production of sand-lime brick to \$961,226. The number of plants reporting made a rapid growth from 16 in 1903 to 94 in 1907, with a slight decrease in 1908, to 87. Common, front, and fancy brick were manufactured from sand and lime in 1908. The average price per thousand for common brick was \$6.63, as against \$6.61 in 1907 and \$6.71 in 1906; for front brick the price was \$12.16, against \$10.96 in 1907 and \$10.42 in 1906. In 1908 common brick composed 83.57% of the value of all bricks and front bricks 15.37%.

*Abstract from *Daily Consular and Trade Reports*.

THE MINING MAN'S INTEREST IN LAND CLASSIFICATION.

Written for the MINING AND SCIENTIFIC PRESS
By GEORGE OTIS SMITH.

*The classification of the public lands is at the foundation of both effective administration of the public lands and of the enactment of proper land legislation. On this account the discussion of this subject is germane to this Mining Congress, and no class of citizen should extend more hearty support to the Federal Government in its work of land classification than those who are interested in the honest and intelligent development of the mining industry. The work of classifying the public lands was authorized by Congress in 1879 and was then specifically assigned to the Geological Survey, which was also intrusted with the investigation of the mineral resources of the country. The relation of land classification to the mining industry appears to have been uppermost in the minds of those who were active in creating the Geological Survey, and of those who shaped the legislation to that end. That this duty was not definitely accepted in the early days of the Survey now seems unfortunate in that the opportunity was lost for a scientific classification of the public lands before the larger part of the more valuable areas had passed into private ownership. Yet the years have been well spent in the important task of determining the natural resources of the public domain, in training a force of geologists and engineers competent to do this public land work, and in winning the confidence of the people in the ability and integrity of the Survey as an organization. The results of the land-classification work undertaken by the Geological Survey three years ago, and now in progress on an extensive scale, derive their value from the existence of this body of trained men and from the large stores of geologic, topographic, and hydrographic information collected in the course of the Survey's investigations.

The classification of the public lands as now prosecuted by the Geological Survey serves two important ends, one administrative, the other legislative, and I believe that both were contemplated by Congress at the time of the creation of the Survey. The work of the Survey since 1906 on the public coal-lands constitutes its largest contribution to land classification. The primary purpose of these classification-surveys in the coal fields of the public-land States is to promote the utilization of these great fuel reserves, the most important natural resource to which the people retain an unquestioned title. Under the regulations setting forth the plan of valuation of Government coal-land the price is determined on the basis of estimated tonnage and the unit rate varies with the quality of the coal, ranging from $\frac{1}{2}$ to 3c. per ton for coal deposits within 15 miles of a railroad. The prices thus calculated for the public coal-deposits average less than one-tenth the usual royalty paid in the West, yet this conservative valuation will more than double the average price of the public

coal-lands, not to mention the fact that this policy of land-classification has stopped the illegal disposal of coal-lands at even less than the minimum coal price. I maintain that the Government valuations will not impede the disposition of the coal-deposits for purposes of utilization. The real development of the West will be promoted, not retarded. As the public lands are now administered the honest coal entryman need no longer fear the unfair competition of the less scrupulous who may enter 160 acres of coal land as a homestead.

In the Western oil fields the classification-work by the Survey has resulted in protecting the oil man from the agricultural claimant, and with a better law the reports of the Survey geologists would also protect the oil prospector from the devices of the gypsum entryman. The next move on the part of the Federal Government in its capacity as the present owner of a large acreage of oil lands should be to protect the oil industry from itself by preventing injury to future productiveness by reason of reckless drilling and by discouraging production in advance of possible disposal.

At the present time it is generally realized that natural wealth is the source of national prosperity, and the rational utilization of natural resources is recognized as the only means to continue that prosperity. Utilization is opposed alike to non-use and to waste. To withhold the land from private use except where public use is of greater advantage to the people, is to check national progress; to dispose of the people's land for other than its highest practical use is to waste that property and to betray a trust. The public-land problem thus resolves itself into, first, the determination of the best use to which the public domain can be put, and second, the disposition or reservation of the land now belonging to the nation so as to assure that use. Such a land-policy needs no defense, for it is based on the safe principle of the greatest good to the greatest number.

To attain this high aim of making the best use of the public land, legislation is necessary, and as a preliminary to legislation exact knowledge is required in the form of a scientific land classification. In a number of instances Congress has already used the results of investigations by the Geological Survey, and at the present time land-classification work of several types is in progress, which has the definite purpose of aiding proposed legislation. For instance, phosphate-land surveys are now being made to furnish authoritative information to be placed before Congress for its use in legislation to promote the best development of these important deposits of mineral fertilizers. This effort to secure special legislation is inspired by no dog-in-the-manger spirit, and no attempt to keep the people out of the public domain is contemplated. The mineral law in its application to deposits of phosphate-rock is equivocal, and the present investigations are being made with the sole purpose of placing the facts before Congress. Whatever legislation is proposed, it surely will not be restrictive of development for the good of this nation, nor will it look toward the non-use of the earth's bounty, but rather toward the promotion of

*Address presented before the American Mining Congress, Goldfield, Nevada, September 30.

the mining and utilization of this valuable rock, on which the nation's agricultural life will later depend.

As another line of land-classification work in aid of legislation I may cite the water-power investigations. The information available as to the undeveloped water-powers of the United States is far from complete, but to a large extent it represents the work of the Water Resources and Topographic branches of the Geological Survey. With these earlier records and surveys as a basis, the Survey is now actively engaged in examining power-sites to which the Government still retains the title. Again, the purpose is to aid in the enactment of legislation that may promote and not hinder development of these water-powers as rapidly as the industrial, transportation, and other needs of the nation demand. Those who are making a study of the water-power problem fully realize that economical utilization of these natural stores of energy requires their development on a larger scale with the investment of capital in large amounts. The day is past for inexpensive, inefficient developments where only the minimum flow is used. Keeping in mind the present demand for power that can be depended upon, we need not look far into the future to see storage as a universal factor in water-power development. Utilization of the undeveloped water-powers on the public domain, therefore, involves either Government development or long-time leases of these power-sites to strong financial interests, and in the latter event the law must provide for effective Government control that will insure that the profit upon the capital accomplishing the development cannot impose unjust burdens upon the users of the power, whether the utilization be for transportation, city lighting, or motive-power.

The recommendations made by the Geological Survey have already resulted in 46 temporary withdrawals by the Secretary of the Interior of power-sites on 42 rivers in seven of the public-land States. Were I to present a map showing the distribution of these power-sites now temporarily withdrawn, their relation to the great mining districts of the western country would be at once noticeable. No better argument could be presented to convince one that the Federal Government deserves hearty support in this matter of land classification. Many already realize the importance of Federal protection through legislation to the small operator of the future. The Governmental control of power-charges may mean the difference between the closing down of a mine and its operation at a profit.

An adequate classification of the public lands is furthermore essential to the development in the land-laws of the principle of relative worth, which is that the land must be so disposed of or so reserved as to secure utilization for the purposes for which it is most valuable. No principle is more fundamental to real conservation, and at the same time more beneficial to the mining industry, than this of giving preference to the highest possible use for the public lands. The earliest land-laws, those of a century ago, provided for the reservation of mineral lands from disposal for other purposes, and the present coal-land law expresses this principle of relative

worth by giving gold, silver, and copper deposits priority over the coal, and coal in turn preference over agricultural values. These distinctions necessitate land-classification based on adequate field examination, and with classification data at hand the principle of relative worth can be further developed. Wherever the different values conflict the higher use should prevail. For example, the reservation or disposal of a tract of land for a dam or reservoir-site should have preference over its use for agriculture.

The best example is afforded by the case of agricultural and mineral lands in national forests. The principle of relative worth is recognized by the statute which specifies that it is not the intent of the act providing for these forest reservations "to authorize the inclusion therein of lands more valuable for the mineral therein, or for agricultural purposes, than for forest purposes." Classification-work in the form of topographic surveys by the Geological Survey in the national forests is specifically provided for by appropriation, and last year Mr. Garfield, speaking in behalf of this item before a congressional committee said: "It is the part of wisdom to do this work in the forests at the earliest practicable date, because it will make possible the elimination from the national forests of areas which ought not to be there."

On the other hand, wherever the different values can be separated, that separation by appropriate legislation is at once the easiest and best solution of the problem; for instance, the surface rights may be separated from the right to mine underlying beds of coal. The first step in this direction was taken in March of this year in the passage of the Mondell Act for the protection of the surface-rights of entrymen, whereby the home-seeker may secure all for which he made entry—all that he swears he is getting—while the coal beneath his tillable land is reserved to the nation for future disposal.

Land legislation of the future should strengthen this principle of relative worth where it already exists in law, and introduce it further in all new legislation. In his report as Commissioner of the General Land Office two years ago, the present Secretary of the Interior expressed this same ideal in land legislation and administration, stating that the end to be sought is "that the remainder of the public lands shall be devoted to their greatest beneficial use for the States as well as for the Government at large." To accomplish this I would add that land classification must be scientific and detailed in order that data may be available for the guidance of Congress in wise legislation and of the executive officer in just administration of the public lands. Such a classification should not be an arbitrary dictum, nor is it necessarily final, but as Mr. Ballinger put it "there should be reposed in the Secretary of the Interior the continuing power of re-classification to meet changing conditions, which may necessitate the transfer of lands from one class to another." As to re-classification I assure you that the Geological Survey stands ready at all times to review and revise its land classification in the light of changed conditions, new data, or discovered errors in previous work. A scientific bureau could not take any other position.

GOLD ORE NEAR NEWCASTLE, COLORADO.

Written for the MINING AND SCIENTIFIC PRESS
By FORBES RICKARD.

An interesting discovery of gold ore in commercial quantity comes from a region that for more than 200 square miles has never been known in connection with precious metal mining. This is instanced in the carload shipments of sulphide ore carrying from 1½ to 2 oz. gold from a new mine development near Newcastle (on East Elk creek, on the White River Forest Reserve, Garfield county, Colorado. Newcastle and the country tributary to it has been long known as a coal mining centre. The accompanying illustration shows the quartzite sedimentaries below the limestone of the coal measures, lying on the eroded surface of the underlying Archean gneiss and crystalline schists.

This proximity of coal measures with deposits containing ore of gold and silver in marketable quantity

lower horizons in the intervening 750 ft. to the bed of Elk creek below and other adits will follow the discovery work above described. The covering of the vein by talus heaps and rock slide has made difficult the prospecting for lower sites.

Though such discovery as this may not mean the bringing in of a new camp of any great importance, it at least marks the beginning of a prosperous mine and points to interesting possibilities in the way of mine discoveries where they are least expected.

DRESSING AMALGAMATING PLATES.

Under the new gold-law regulations, in the Transvaal, covers with double locks have to be used on all mill-plates. This necessitates the presence of two men each time the covers are removed, and as every dressing entails extra labor and the withdrawal of shift-men's attention from the running of the mill, it is evident that reduction in the number of plate-dress-

Coal Measures Overlying Archean Rocks Near Newcastle, Gold Mine Dump is Near the Centre of the Picture.

adds interest to the discovery and serves to recall other instances in Colorado where coal and gold fields are almost contiguous. There is the Ten Mile district, near Leadville, where zinc ore containing silver was mined from the Robinson limestone which constitutes the base of the lower coal measures in that locality; another in the case of the Crested Butte anthracite deposits in close proximity to silver mines, and still another case, but further removed, is the mining of ores of gold and silver in the gneiss and crystalline schists of the foothills that flank the coal and oil fields of Boulder county.

This Newcastle gold mining development dates back a few months only and credit for its development belongs to the Western Investment Co., and its manager, F. V. Bodfish. In the illustration there is shown the opening of an adit which is about 100 ft. in length. As far as the work has gone a continuous vein occupying a fault fissure in the gneiss has been followed. It varies in width from a few inches to 2½ ft. An average of something more than one foot of heavy iron sulphide with a gold content of from \$30 to \$40 gross assay value is found. This valuation is based on sampling made at close intervals for the distance driven. The adit gives from 125 ft. to 130 ft. of 'backs' and the vein has been picked up at

ings would be beneficial, provided the total extraction be not detrimentally affected. Trials were accordingly undertaken, with the result that the extraction was higher for periods of 12-hour dressings, but on the other hand, and in part explanation of this, the gradings show a finer product passing over the plates during that trial. A further experiment, covering a period from February 11 to April 19, 1909, was undertaken to determine the extraction at different intervals between the dressings of the plates, and the results showed that the extraction progressively improves up to six hours from the time of dressing plates, and then falls off again, until at the end of 12 hours it has dropped to 49.10%, or 0.09% lower than that obtained three hours after dressing. The highest extraction of 53.57%, obtained six hours after dressing, has an original value of 8.38 dwt., while for the lowest extraction, 49.10%, obtained 12 hours after dressing, it is only 7.79 dwt., this being the lowest original value on the tables. The plates must be in good order, and a sufficient setting of amalgam left after the clean-up. If the plates are scraped to bare copper, a practice only too common, good amalgamation will not be obtained even with dressings every hour.—G. O. SMART, Jour. Chem., Met., and Min. Soc. of S. A., June '09.

ASSAY OF CYANIDE PRECIPITATE.

Written for the MINING AND SCIENTIFIC PRESS
By FRANK A. BIRD.

Although an abundance of information upon the cyanide process is published in the MINING AND SCIENTIFIC PRESS, I have failed to observe any upon the present day practice of assaying the precipitate. Believing that such will be of value to readers of the PRESS, I herewith submit the methods as commercially carried out in the Salt Lake district.

First method. While no special directions as to fluxing for the preliminary fusion are necessary, the following flux-mixture has been found to give perfect results. It can also be used as a fire-assay lead-flux, and, with the addition of litharge, for silicious gold and silver work.

The following is the flux-mixture:

| | Per cent. |
|--|-----------|
| Sodium carbonate (soda ash grade), 4 lb..... | 38.1 |
| Potassium carbonate, 4 lb..... | 38.1 |
| Flour, 1½ lb..... | 14.3 |
| Borax glass, 1 lb..... | 9.5 |

The crucible charge consists of: 18 gm. flux mixture, having a reducing power of about 25 gm.; 3 gm. borax glass; 50 gm. litharge.

This thoroughly mixed in a 20-gram crucible, and then 1/10 assay ton of precipitate, which has been carefully weighed upon a delicate analytical balance, is added and again mixed well, the mixing spatula being brushed into the crucible as it is removed; a light cover of soda is then added. About nine crucibles are prepared in this manner, three of which will be used for the silver assay alone, the balance for the gold. The prepared crucibles are placed in a muffle at not too high a temperature, although no special precautions are taken to have it extremely low for gold-precipitates. After quiet fusion is attained the crucibles are heated intensely for a half hour, the furnace being fired lightly about every 10 minutes. As the melts are poured, cover each with an inverted scorifier to prevent the slag flying as it cools. Slag and cube the buttons, as usual, saving the three slags representing the silver part together, and the six for gold together. As it is necessary to know the approximate gold-content of the sample the three buttons representing the silver assay are first cupelled; as this cupellation finishes, a play of colors will be noticed upon the button wholly unlike any ordinary cupellation; this is due to some zinc which has been reduced and has remained throughout the operation; it may be necessary to push the cupels a little farther back in the muffle before this totally disappears, and it may last from five to ten minutes longer than would the ending of an ordinary cupellation. Clean the buttons over a pan containing slags, and to which the cupels, cleaned free from unused bone-ash, have been added. The buttons are weighed and entered in the work-book as ounces of gold and silver.

To the six lead buttons, representing the gold assay, are added five times the weight in milligrams of the cupelled silver buttons, and ten milligrams of pure copper, which will prevent the buttons spitting as they finish. These are then cupelled in the ordin-

ary manner, no special precautions being necessary. After brushing the gold buttons over a pan containing the six slags and cleaned cupels, they are placed separately, without any flattening, in parting capsules containing hot nitric acid (2 parts of acid to 1 of water). Parting proceeds quite vigorously, the gold flouing into one sponge; should it be necessary the buttons are assisted in breaking up with a glass rod, but if the specified quantity of silver has been used, and the parting-acid is hot, and of the concentration indicated, it rarely happens that they require any further attention than most careful watching and regulation of the heat of the parting-plate. After the parting finishes, decant the acid and add another quantity of the same as a precaution; heat cautiously as it is inclined to 'bump', and continue about 15 minutes after steam begins to show, then decant, wash twice with ammonia water and once with pure distilled water, dry very carefully, burn, weigh, and enter in the work-book as commercial gold assay. This deducted from the ounces of gold and silver makes the commercial silver assay.

Working by this method reduces to a minimum the chances of reporting silver with the gold. I have dissolved gold buttons which had been alloyed with three times their weight of silver and parted as coronets, and found that they contained as much as 13 oz. silver.

The two sets of slags and cupels are first weighed, and then crushed to about 30-mesh. Two crucibles are run for silver and four for gold, the quantity taken being the nearest 50 gm. the total weight can be subdivided into. The charge is as follows:

18 gm. flux-mixture, 10 gm. borax glass, 6 gm. fluorspar, 30 gm. litharge, 50 gm. slag and cupel mixture.

Mix well in the original crucibles, cover lightly with soda, and fuse at not too high a temperature, as it boils badly and requires constant watching; add salt as usual when the danger point is reached. When quiet fusion is attained heat at a high temperature the same as was done with the precipitates. pour and cupel as usual; the gold buttons can be parted direct, sufficient silver being present. Weigh the buttons in fractions of milligrams and calculate to the weight of the total mixture, and then to ounces; deduct the weight of the pure gold found from the silver buttons, and then add each to the commercial assays, which makes the corrected assays for report.

Metallies are usually received finely divided; these, when submitted with the fine material, are assayed the same, about two crucibles for silver and four for gold being run; if the precipitate assays low in silver no correction is deemed necessary, but one is always made for gold.

The above method outlines the scheme as applied to gold precipitate. Silver precipitate is assayed in precisely the same manner; the first fusion, however, must be commenced with an extremely low heat, the muffle gradually being brought to redness as the fusion proceeds, otherwise the results are low, probably from volatilization. Six crucibles are enough for the gold, each button being parted separately with one part of nitric acid to eight of water.

Second method. This is applicable to gold preci-

pitrite, but not to silver. The preliminary preparations are the same as in the first method, but only six crucibles are necessary; cupellation must be carried out as the assay for silver, otherwise any zinc not driven off will be reported as gold. The gold-silver buttons, having been weighed, are dissolved separately in aqua regia (1 part nitric acid, 3 to 4 parts hydrochloric acid, these to be diluted once). The gold dissolves quickly, the silver precipitating as chloride; after solution of the gold, dilute to about 100 c.c. and stir well, allow the silver chloride to settle, then filter upon small paper; wash thoroughly with cold water, place in scorifiers, carbonize in the front of the muffle, then add 30 gm. granulated lead, a pinch of borax-glass, and scorify; cupel and weigh as the commercial silver assay, and this deducted from original weight gives the commercial gold assay. As a precaution buttons may be parted for gold; none should be found. The slag and cupel-mixture from the crucible assays must be assayed for gold and silver, about two crucibles for silver and four with an addition of silver for gold; the scorification slags and cupels should also be run for silver. Instead of mixing all the slags and cupels together, a slag and cupel from each assay may be pulverized together, then divided into two parts and run in the original crucible, and in one new one, the two buttons being weighed together and added to their assay.

Although methods have been applied recommending the all-scorification method in preference to the crucible, my experience has been that while the commercial assay is higher the corrected assay is far below. I believe the crucible assays, as outlined above, answer every purpose, and are equal to any method used in present practice. For gold work only, commercial litharge will be found as satisfactory as the higher-priced chemically pure article. Cupels are preferred that are very soft; this is accomplished by making the bone ash barely moist with water and compressing very lightly. Nothing but the bone ash and water is ever used.

PROTECTION OF MINE INVESTORS.

The Mining and Metallurgical Society of America has formulated an opinion after a year's deliberation on what stockholders of mining companies should expect to find in the annual reports issued by such companies. It believes that this is a matter of interest to every legitimate investor in mining securities. That many stocks are highly overvalued is a fact notorious among mining engineers. To affirm this as a fact implies no disloyalty to the business itself, for the mines of the country produce two billion dollars worth of output each year, and employ probably two and a half million men. It seems inevitable that a business of such proportions must be more and more consolidated, and must furnish a legitimate field for the investment of the savings of the public. If mining stocks were valued on sane and proper principles they would be as sound securities as any on the market. Indeed some of them are today.

But loyalty to the business itself is one thing; support of the inflators of mining stocks who pre-

sume to represent the mining business is quite another thing. The inherent illusion by which mining stocks are overvalued is the capitalization of the dividends of mines on the same basis that the income of railroads and other permanent businesses is capitalized. This ignores the fact that a large number of mines are short lived. Innumerable stocks are sold at such a price that their dividends will make a return of only 3 to 4% annually, and yet their expectation of life may be only a few years.

The Mining and Metallurgical Society of America consists of mining engineers, mine managers, metallurgists, and geologists. It was organized about a year and a half ago to discuss questions of importance to the profession of mining. Its membership is now about 150, and while not all the prominent men in the profession have joined, it may fairly be said that the Society's membership is drawn from the mature and conservative part of the profession and that it contains many eminently successful men. Its expressions are merely opinions; they do not bind even the members to any course of action, but the Society offers to the public the almost unanimous belief of its individual members.

The resolution on this subject, as adopted by the Society, reads as follows:

Whereas, The over-valuation of mining properties by investors and the public, due to ignorance of mining conditions and a lack of appreciation of the real nature of the investment, tends to increase unduly the profits of mine promoters and speculators, and to increase unnecessarily the financial risks taken by mine investors, to the ultimate disadvantage of the mining industry,

Resolved, That it is the opinion of the Mining and Metallurgical Society of America that, for the protection of shareholders and investors, every mining company should publish an annual report within 90 days from the close of its fiscal year, and such report should incorporate the following information:

(1) A brief review of the past history of the property, the work accomplished and the results obtained, with tabulated statement of expenditures and receipts from the beginning, marketable products made each year, and the sums received from the sale of same, the annual net earnings, and the disposition made of such earnings.

(2) A similar review, but in more detail, of the work of the year, with statements of the assets and liabilities (these statements to show all details as to capitalization of the company; the number and classes of shares outstanding at the date of the report; the respective rights of these shares; the number of shares remaining in the treasury; any options or contracts on such shares; any bonded indebtedness), receipts and disbursements, cost-sheet and other information as to work accomplished and results obtained.

(3) A statement of ore reserves at the date of the report, compared with the reserves of the previous year, with an estimate, by a competent authority, of the probable life of the mine.

The Inca Mining Co., operating a gold mine in the district of Carabaya, Peru, will erect a 100-stamp mill during the coming year.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Charcoal-iron is produced in the United States usually to the extent of nearly half a million tons per annum, although last year the amount fell to 249,000 tons. It is turned out by 17 States, the largest quantity, 143,000 tons in 1908, coming from Michigan.

Tube-mill costs at the Waihi gold mine in New Zealand are 28c. per ton. The power-costs constitute 12c. of this amount, the flints and liners 14, and the labor, repairs, and miscellanies 1½. These mills are grinding to 150 mesh. In Mexico the ores are usually ground to 200 mesh in tube-mills.

Antimony exists in large deposits in the Department of Ancachs, Peru, most of which are rich in silver. These are found in the vicinity of Huaraz, in the district of Recuay. There are also important deposits in the Department of Huancavelica, in which the ore as mined will assay from 40 to 50% Sb.

Under the recent mining act of California a claimant who fails to make the annual expenditure upon his claim is disqualified from re-locating the ground embraced in the original location or mining claim or any part thereof under the mining laws within three years after the date of the original location. Any attempted re-location thereof by any original locator renders such location void.

Copper absorbs hydrogen, carbon monoxide, and sulphur dioxide. The solubility for those gases increases with the temperature and decreases with the oxygen-content. With set copper the solubility of the gas is at a minimum on account of the low temperature and the high percentage of oxygen in the metal, and set-copper solidifies with a depressed surface.

Furnace-efficiency in boiler heating depends to a large extent upon proper regulation of the air supplied for combustion of the fuel. In ordinary good practice an excess of 30 to 40% of air over theoretical requirements is admitted. To find the percentage of excess-air, subtract the observed percentage of CO₂, as determined by an indicator, from 20.7; divide the remainder by the CO₂ percentage, and multiply by 100.

Cuban iron ore has been developed on a large scale by the Spanish-American Iron Co. The deposits are in the Province of Santiago de Cuba, and boring-tests have proved a total of 600,000,000 tons. Other deposits of almost equal magnitude exist at Moa and at Baracoa. The company above named is expending \$5,000,000 in railways and other improvements needed for working the mines, the present output of which is 12,000 tons per diem.

Seprentine usually occurs massive, or in imbedded grains, and masses in the parent-rock. It sometimes forms seams resembling veins, depending upon the distribution through the original rock of the min-

erals from which it was derived. It is an alteration product from magnesian silicates, such as olivine, pyroxene, amphibole, enstatite, and mica. It is frequently associated with dolomite, and often contains considerable amounts of the partly altered original minerals.

Silver in ores is usually combined originally with sulphur, together with considerable amounts of antimony and arsenic. Oxidation results in forming silver sulphate, and there are generally sufficient chlorides present in the ore and waters to precipitate it as silver chloride. This is soluble to only a slight degree, hence secondary enrichments of silver ores are not so common. Depletion of the silver content of ores, however, occurs in many places. At Cripple Creek, Colorado, the silver has been abstracted to a notable extent from the gold ore near the surface. This is not the general rule, the gold ratio usually increasing with depth.

Magnesia is recovered from the chloride at Stassfurt, Germany, by mixing with calcined magnesian limestone in the ratio of 10 to 4. Water is added to make a thick pulp, which is then agitated. Lime chloride and magnesium hydrate are thus formed. The pulp is filter-pressed, the magnesium hydrate remaining on the filter. This is then washed, and calcined to drive off the water of crystallization. From the liquor issuing from the press the calcium chloride is also recovered.

Patent requirements and costs for an association placer claim, consisting of an area equal to 8 individual claims, or 160 acres in all, are, first, \$500 worth of work must have been done as a condition precedent to applying for patent; if on surveyed land re-survey is not necessary; in unsurveyed territory a survey must be made. The cost of that will depend upon the contract with the surveyor; deputy mineral surveyors usually charge from \$10 to \$15 per day, including time spent in office-work, and they require two assistants. Publication of notice will cost about \$20; Land Office fee, \$10; and for the land itself, \$2.50 per acre. In addition there will be attorney's fees, these being dependent upon contract.

Derecho as applied to land in Mexico is an undivided right, usually proceeding from inheritance. Such rights may exist in lands held by title originally issued to an individual, or in community lands. The law relating to *derechos* is complex. In general it may be said to carry the right to use the natural products of the soil where the exercise of this right does not trench upon rights previously established by the holders of other *derechos*. It also recognizes the right to fence in and use open areas within the lands pertaining to the estate, and the improvements made belong exclusively to the person thus making them. A foreigner may purchase a *derecho*, and it is often a convenient means of securing the right to use necessary areas surrounding a mine. The title to a portion of an estate obtained by purchase is not valid unless all the heirs join in the conveyance, and they are often so numerous that it is impossible to be sure that no necessary signatures to the document have been omitted.

COMPANY REPORTS.

CONSOLIDATED MERCUR GOLD MINES CO.

The report of this historic company for the year ending June 30, 1909, shows net earnings of \$34,005 from a gross income of \$774,417. This does not indicate inefficiency in the management, as every one realizes who knows the difficulties against which it has been necessary to contend at Mercur. The average value of all ore treated was only \$3.58 per ton, and the loss in tailing averaged 88c, leaving a net recovery of only \$2.70 per ton. The costs were only \$2.62 per ton; hence it is plain that one must travel a long way to find better management. The achievement is even more creditable when it is considered that the plant treated only 773 tons per diem; the total ore milled for the year amounting to 282,269 tons. The credit for this performance is due to George H. Dern, the general manager. It may be of interest to note that the costs given, as divided between mining and milling, were respectively \$1.53 and \$1.09 per ton. The cost of crushing is given as 9.6c.; the roasting of 107,007 tons of base ore, \$1.048 per ton; leaching, 41.4c; refining, 47c. In the slime-plant 27,523 tons were treated at a cost per ton of 24¼c. The precipitation cost was 48c., the zinc alone figuring 2½c. per ton of original total treated. The tailing losses consisted of 54c. in the slime, and 72c. in the sand rejected.

Development in the mines was conducted actively through the year, and the manager reports a large amount of unproved ground still remaining in the Mercur mine. Hence the indications are for a long life of this interesting property, where so many metallurgical experiments have been tried, resulting in the enrichment of metallurgic practice in general.

MONTANA-TONOPAH MINING CO.

The properties of this company are adjacent to the famous Mizpah mine at Tonopah, Nevada. It will be remembered that it was necessary here to sink over 200 ft. through later eruptives to reach the early andesite, the productive rock of the district. Fortunately the site chosen brought the shaft directly on the vein. Faulting is, however, so frequent in all this ground that the veins are only followed with great difficulty, and much shoveling of ore and tramming on intermediate levels is necessary. This accounts for the high cost of development shown by the report of Edgar Collins, the superintendent. In July 1908, the Triangle vein, or veins, was discovered. The new system consists of two, and in places three, veins which are more recent in age than those first developed. They are more regular, less faulted, and they extend below the andesite and into the dacite. The ore is partly oxidized, and contains an iron-stained clay which has caused trouble in the mill, owing to difficulties in inducing settling. The Triangle vein was discovered on the first or 396-ft. level, and has since been developed on the second, third, fourth, and intermediate levels. While, according to Mr. Collins, no orebodies of great size or richness have been found, the orebodies on this vein system show unusual continuity as compared with other veins in the property, and have yielded a large tonnage of ore. On the 396-ft. level 660 ft. of development has been accomplished on the Triangle veins. One of the orebodies found is practically continuous for 450 ft. Additional ore has been found on parallel stringers. On the 462-ft. level two parallel ore-shoots have been developed. The first, on the foot-wall vein, is 160 ft. long and has an average width of 2½ ft. The second, on the main vein, is 350 ft. long and is 4 ft. wide at the west end. On the 515-ft. level the vein has been opened 400 ft., practically all the way in ore, and averages 2 to 3 ft. wide. The vein is productive both in the andesite and the dacite; a fact of considerable significance as regards the life of the mine and of the camp. The Triangle vein has also been developed on the 615-ft. level. Within the year a diamond-drill hole was put down 860 ft. on the 765-ft. level. The Tonopah rhyolite-dacite was encountered at a depth of 750 ft., thus settling certain structural problems. Further development is being done by cross-cutting.

During the year the mine produced 41,692 tons of ore, practically all of which went to the mill, and 11,853 tons of waste. In addition 7848 tons of ore was milled for the MacNamara mine. Of the ore mined, 10,947 tons came from the first, 395-ft., level, and 1220 tons from the old dumps. The total mining cost for breaking and handling the ore amounted to \$3.47 per ton. The cost of development amounted to a further charge of \$1.645 per ton. The distribution of development costs and of mining costs for 11 months, covering 37,464 tons, is shown below:

| DEVELOPMENT COST. | | |
|---------------------------------|--|---------------|
| Labor: | | Per ton. |
| Breaking | | \$0.466 |
| Timbering | | 0.075 |
| Hoisting and dumping..... | | 0.108 |
| Foremen and shiftbosses..... | | 0.030 |
| Blacksmith sharpening | | 0.030 |
| Shoveling and tramming..... | | 0.393 |
| Surveying | | 0.023 |
| Watchman | | 0.009 |
| Storekeeper and timekeeper..... | | 0.006 |
| Diamond-drill hole | | 0.075 |
| | | <hr/> \$1.215 |
| Supplies: | | |
| Breaking | | 0.362 |
| Timbering | | 0.021 |
| Hoisting and dumping..... | | 0.049 |
| Hoisting—electrical power | | 0.061 |
| | | <hr/> 0.493 |
| | | <hr/> \$1.708 |

| MINING COST. | | |
|---------------------------------|--|---------------|
| Labor: | | Per ton. |
| Ore breaking | | \$0.826 |
| Timbering | | 0.187 |
| Hoisting and dumping..... | | 0.285 |
| Blacksmith sharpening | | 0.050 |
| Surveying | | 0.060 |
| Foreman and shiftbosses..... | | 0.077 |
| Sampling | | 0.026 |
| Assaying | | 0.025 |
| Shoveling and tramming..... | | 0.915 |
| Watchmen | | 0.021 |
| Storekeeper and timekeeper..... | | 0.015 |
| | | <hr/> \$2.487 |
| Supplies: | | |
| Ore breaking | | 0.486 |
| Timbering | | 0.174 |
| Hoisting and dumping..... | | 0.129 |
| Hoisting—electric power | | 0.161 |
| | | <hr/> 0.950 |
| | | <hr/> \$3.437 |

The cost of drifting was \$6.56 per foot; of cross-cutting, \$5.44; of raising, \$4.65; of sinking winzes, \$11.92; and of diamond-drilling, \$3.28. The average assay value of the ore mined was \$14.57 per ton. The recovery was a trifle over 90%, and the milling cost \$3.75, to which should be added 15c. for mill construction. The total cost of bullion was 55c. per ounce, and the price realized was 72 cents.

| The following summary of expenditures is given: | | |
|---|--------------------------|------------------|
| | Cost for 41,692 tons. | Cost per ton. |
| Mining | \$144,677.01 | \$3.470 |
| Development | 68,588.90 | 1.645 |
| Shipping and selling... | 3,556.49 | 0.086 |
| General maintenance .. | 6,793.38 | 0.163 |
| *General expense | 18,403.31 | 0.441 |
| | <hr/> \$242,019.09 | <hr/> \$5.805 |
| Milling | \$186,348.36 | \$3.762 |
| Mill construction | 7,432.04 | 0.150 |
| **Custom milling | 5,891.50 | 0.119 |
| Royalty | 5,211.00 | 0.105 |
| | <hr/> 204,885.90 | <hr/> 4.136 |
| | <hr/> \$446,901.99 | <hr/> \$9.941 |

*Office salaries, etc.
**Handling custom ore from cars to ore-bin.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

CONTRACT OF SALE OF MINES—CONSTRUCTION.

A contract for the sale of certain mines permitted the purchaser to develop the mines, and provided that part of the proceeds should be paid on the purchase price. Under the agreement the purchaser was allowed \$12 per ton for ore treated on the premises, and that on ores better adapted for shipment directly to a smelter a further allowance was to be made. On a disagreement and a dispute as to whether the purchaser was entitled to the \$12 per ton on ore shipped to the smelter the construction put upon the contract by the parties themselves and by the purchaser on the deposit of a deed in escrow was said to control; and it was immaterial whether such construction was regarded as a modification of the contract or an interpretation thereof.

Powers v. Worlds Fair Min. Co., (Ariz.) 100 Pac. 955, March '09.

CONTRACT FOR SALE OF MINES—PAYMENT AND POSSESSION.

A contract for the sale of mines permitted the purchaser to take possession and develop such mines, and provided that part of the proceeds should be paid on the purchase price by depositing in a bank the net proceeds from the sale of the ore within 15 days after receipt thereof, and on his failure to do so the deed placed in escrow should be returned. In an action for damages for dispossession on the failure to make such deposit, the court decided that the contract was entire and that the purchaser's right to remain in possession of the mine depended upon the deposit of the proceeds of the ore as required.

Worlds Fair Min. Co. v. Powers, (Ariz.) 100 Pac. 957, March '09.

LOCATION OF MINING CLAIM—RECORDING NOTICE.

The statute of Alaska includes in its provision the recording of notice of mining location. But the following provision, "provided notice of location of mining claims shall be filed for record within 90 days from the date of the discovery of the claim described in the notice," was held not to require, but merely permitted the recording of such notice; nor did it provide that the failure to provide such notice should work a forfeiture of rights; and such a forfeiture does not follow in the absence of a well-established rule or custom of the miners of the district to that effect.

Sturdevant v. Vogal, 167 Fed. 448, Feb. '09.

LOCATION OF MINING CLAIM—EFFECT OF ERROR IN NOTICE.

An error in the location notice of a mining claim in its reference to the location of a permanent monument, was held not material in an action between the original locator and the subsequent locator, where it was shown that the claim was properly marked by stakes, and where it further appeared that such subsequent locator never saw the notice and could not have been misled thereby.

Sturdevant v. Vogal, 167 Fed. 448, Feb. '09.

MINING CLAIM IN FOREIGN COUNTRIES—APPLICATION OF STATUTE.

The United States statutes governing the rights of co-owners of mining claims where a part of such owners have done all the assessment work thereon, have no application to mining property situated in a foreign country.

Gaines v. Chew, 167 Fed. 630, Feb. '09.

DEED—RESERVATION OF MINERALS.

In a deed conveying certain lands a reservation of 'all minerals' was held to include petroleum, oil, and gas.

Weaver v. Richards, (Mich.) 120 Northwest. 818, Apr. '09.

Dividends.

On Monday, October 4, the Bunker Hill & Sullivan Mining & Concentrating Co. paid dividend No. 145 of \$45,000. This makes the amount of dividends paid since January 1, 1909, \$525,000, and the total to date \$11,196,000.

Publications Received.

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

THE MINING LAW OF CANADA By Alfred B. Morine. pp. 338, index. The Cromarty Law Book Co., Philadelphia, 1909. Price \$7.50.

The appearance of this work on Canadian mining law is most opportune in view of the fact that more than 10 years have elapsed since the publication of a similar treatise. The author has made the following division of his subject: (1) Mining Terms and Phrases; (2) Laws in Force (Dominion and Provincial); (3) Crown Title and Minerals under Railways, etc.; (4) Rights of Owners, Right to Let or License, Dower, Partnership; (5) Contracts; (6) Licenses and Leases; (7) Easements and Fixtures; (8) Taxation and Registration; (9) Wrongful Abstraction and Criminal Offences; (10) Employers' Liability. An appendix contains the mining regulations applicable to Dominion lands, and the statutes of those provinces in which mining transactions are now most active. To the student of American mining law this work will prove of great interest as a comparative study. While the absence of the extra-lateral right tends to simplify the mining jurisprudence in Canada, there is the same complexity and confusion that exists in the United States owing to the fact that most of the provinces in Canada have their own individual statutes, while there are still other regulations applicable to Dominion lands. It is interesting to note the frequency with which American cases are cited, owing to the fact that many of the points discussed by the author have never been presented to the Canadian courts for determination. The fact that the law relating to mines in Canada has not assumed the importance there nor been brought before the courts for determination with the frequency that has been the case in this country, has enabled the author to devote a considerable portion of the work to a consideration of related subjects of a less specialized nature, such as the law of contracts in all its aspects, employers' liability, easements, fixtures, and others. Because of the elaborate nature of our mining jurisprudence the treatment of the subject of mining law in this country is usually confined to an exposition of specialized features only, of such general subjects. Mr. Morine's work is a valuable addition to the literature of Canadian mining law.

TIMBERING AND MINING. A TREATISE ON PRACTICAL AMERICAN METHODS. By William H. Storms. 8vo., 280 pp., ill., index. McGraw-Hill Book Co., New York, 1909. Price \$2.

Mine timbering is strictly and absolutely an art; it is a development from experience, and cannot be reduced to scientific rules capable of mathematical expression. The pressures and even the directions of the strains which the miner has to meet are usually unknown and unascertainable. Nevertheless, the safety of mining to a large extent reduces to reliance upon the adequacy of the timbering. Hence the study of methods found suitable is of the highest importance. Mr. Storms has devoted long attention to this subject, and has collected a large amount of data, put together in book-form, making a work which will be widely appreciated. He discusses timber and its preservation, proper forms of sets for drifting, under all conditions; comparison of structural steel with timber for underground use, special applications of timber to gravel-mining; shaft timbering; simple head-frames; details of framing; station timbering, and so forth; all elucidated with well-executed illustrations. Stopping and stope-supports are treated in large detail. Mr. Storms has also undertaken to describe methods of mining, and the descriptions of the systems practiced at Broken Hill, New South Wales, and at the Homestake mine in South Dakota, are of peculiar interest and value. The account given of caving methods, however, is most inadequate, a criticism which must be made of every published description of such procedure. There is room for a special treatise on this subject. The hints given on caving in this volume are suggestive and useful as far as they go. We do not hesitate to say that this work is one of genuine practical utility and should be read by every mine superintendent.

EDITORIAL.

BRITISH engineers are said to be making surveys of Bering Strait to determine the feasibility of a railway tunnel. Nome is likely, however, to continue to depend on steamers for some time.

DISCOVERY of quicksilver deposits in a new locality, fifty miles east of Terlingua, Texas, and thirty miles north of Boquillas is announced. While cyanidation has seriously cut the profits in quicksilver mining the occurrence is none the less important as indicating mineralization of territory additional to that previously known.

PRODUCTS of the mines furnished 83 per cent of the traffic of the Denver & Rio Grande railroad in 1908. Of this amount 40 per cent came from ores and 28 per cent from bituminous coal. The former yielded approximately two million dollars revenue, and the latter three and a half million. If it were not for the mines and the tourists the Rio Grande would not earn expenses.

TIN deposits have been known near El Paso, Texas, since 1899, though no especially vigorous attempt has been made to develop them. The organization of a new company with adequate capital is announced, and shaft-sinking is to be begun at once. The importance of securing additional deposits of tin fully warrants careful exploration of ground even less favorably situated than that in the Franklin mountains, and it is to be hoped that success will crown the new venture.

PETROLEUM of light gravity has been discovered in the Philippines on Tayabas peninsula. Mr. George I. Adams has recently examined the wells and sampled the oil. He considers the showing fully as encouraging as those which led to the development of several fields in the United States. High-grade petroleum from this field would find a ready market for refining in California, where oil from Sumatra is now imported for mixing with lower grade local material.

THE Alaska Central railroad, which is built from Seward to Turnagain arm, was bought in at receiver's sale by Mr. S. G. Jemmett for J. P. Morgan & Co. The same firm, with associates, is building the Copper River & Northwestern railroad from Cordova to the Bonanza mine. The Alaska Central was originally financed by the Sovereign Bank of Canada. The failure of that institution left the future of the road uncertain. It is announced that contracts will be immediately let to extend the Central to the coal fields. The original entrance of the

Morgan interests into the territory argued well for the confidence which it inspired. That additional property should be purchased after personal examination by Mr. G. W. Perkins indicates that abundant capital is to be forthcoming for the development which the region needs.

DEFINITIONS are ever a matter for dispute, but agreement as to them settles many a vexatious question. In this issue Mr. J. W. Finch presents certain definitions for consideration and comment. He endeavors to harmonize as far as may be the differences between the point of view of the observer interested only in the scientific aspects of ore deposits, and that of the lawyer concerned with what one might paraphrase as the 'legal entity' of an ore deposit. This Mr. Finch is particularly qualified to do, but the subject is broad, and further discussion will be welcome.

FESTIVITY will become the serious concern of the San Franciscan throughout the coming week. He is always a festive person, vaunting his Bohemianism, preaching and practising the doctrine that business should not deny the right to pleasure. The special occasion is that of celebrating the one hundred and fiftieth anniversary of the discovery of San Francisco Bay by Gaspar de Portola. Nobody knows how to pronounce his name; the plain man calls it Portóla; the elect insist on Portolá, which sounds elegant; and the ultra-fastidious have secured a decision from the Spanish Academy in favor of Pórtola. If the pictorial forecasts of what is coming should be verified nobody would be able to pronounce it at all by the end of the week, so the importance of the matter dwindles. The great point is that a week of fun and commercial activity seems assured.

REVOLUTION is reported from Nicaragua. Señor Juan J. Estrada is said to have assumed the executive authority in disregard of President José Santos Zelaya. Color is lent to the accuracy of the dispatch from the statement that President Zelaya was at Cape Gracias á Dios at the time. This is in the extreme northeastern corner of the country, from which point speedy return to the capital would be impossible. So far as geographical position is concerned he could not have been taken at greater disadvantage. President Zelaya is reputed to have kept his bank account in Paris, a special train under steam near the palace in Managua, and a fast yacht waiting at Corinto. Evidently he must have been growing bolder to sacrifice his strategic situation by a journey to the far off cape which he would now hardly name so generously and devoutly as did Columbus, to whom it owes its title. A change in régime at present might fittingly usher in the new era of development that seems to be dawning. The equipment on a splendid scale of the Leonesa mine near Matagalpa by the Oroya-Brownhill Company, and the purchase by the same powerful corporation of the Babilonia mine in the Libertad district, have attracted attention afresh to Nicaragua, the stimulus of which has been felt in every mining camp of the Republic.

Mr. Taft's Conservation Policy.

Of the President's speeches none has attracted more attention in the West than that made at Spokane, in which he discussed his attitude toward conservation. The West has peculiar interest in this subject, since here are the great areas of public land over which alone the Federal Government has the authority of ownership; and for the solution of many of the problems of conservation ownership is essential. At present the United States holds important forest lands, water-power sites, and mineral lands; especially those underlaid by coal, oil, and phosphate deposits. It has in addition immense arid and semi-arid agricultural lands, but concerning them the National policy is well settled; the purpose being to get them as rapidly as possible into the hands of actual settlers, and as a means to that end to improve them by irrigation before sale where necessary. In regard to the other lands, conditions are less settled. In the past there has been little attempt to discriminate, and in valuing them acreage has been the principal element. There is now no law by which a water-power site may be sold by the Secretary of the Interior on any different terms than other lands. Yet it is clear that such a site is in most cases of much more value than an adjacent tract of desert, or even unprospected but presumably mineral-bearing land. What the public is coming to believe, also, is that there are the best of reasons why public policy should require that this land, if sold at all, should be sold under conditions which will protect the people against possible extortion by a private monopoly.

Mr. Taft's policy seems to contemplate a considerable change in the laws governing the public lands. The forest lands he believes should be retained and protected, as already provided, only the forest products being sold. The power-sites should be sold, but under restrictions as to their use. In the case of coal, oil, and phosphate lands, surface rights should be separated from mineral rights, the mineral should be valued not by acreage but by quantity and quality, and the lands either retained and leased on a royalty basis, or sold subject to restrictions designed to prevent monopoly. Whether a similar policy will be later recommended regarding other mineral lands no hint is given. Mr. Taft makes entirely clear that all this cannot be accomplished without additional legislation, and he recognizes that the present withdrawals of land are temporary and can only hold until Congress shall have had an opportunity to consider and act. The responsibility rests, therefore, squarely on Congress. Evidently the President anticipates legislation favorable to the policy he has outlined, and certainly if any faith is to be put in political bargains, Congress should give him what he asks in return for his defense of the tariff bill. Congress, however, has a way of its own, and is influenced mainly by what its leaders estimate to be insistent public opinion. Many will find reason to oppose the policy the President has outlined.

There can be no doubt that there is in the West as well as in the East, a deep-seated distrust of monopoly and a disinclination to allow any more of the essentials of life and civilization to pass into

monopolistic control. The economic advantage of centralized control of an industry is discounted by the well-grounded public distrust of the altruism of big business men or the effectiveness of public control of the great inter-state 'trusts'. This feeling has given rise to a multitude of anti-monopoly laws, both State and National. Many of these have been unwise, and the harmful character of the legislation is widely recognized; yet public opinion prevents its repeal. This distrust of monopoly is a strong, if not controlling factor in the situation. In the second place, there is a general social as well as individual interest in the 'unearned increment', and the public has a growing conviction that a part at least of this justly belongs to society as a whole, rather than to somewhat fortuitously selected individuals. No one wants power-sites for what they now are, but for what they may become. The unimproved waterfall does no work, but the public is beginning to feel that its potential dividends for all time to come are at least as valuable as the works which may be built to develop the power. In the case of mineral land this attitude is shown in the general approval of the course of the Government in changing the method of valuation of coal lands from one based on acreage to one based on tonnage. This appeals to the common sense of the man in the street. If a thing is to be sold, why not for a consideration at least approximating its value?

Opposed to these two favoring currents of public opinion are others especially strong in the West. The first and most important is a fear of anything which may retard development. Every city and town in the West has an almost morbid interest in its own growth in wealth and population. Commercial rivalries are keen and 'booming' is a fine and widely practised art. So determined are Westerners to do all that can be done to develop the country at a maximum rate, that neither individually nor collectively is there any hesitation to mortgage the future if need be. The East did it in the years gone by, and the West looks at the results, balances the profit and loss, and is willing to follow the example set. If a street-car line can only be obtained on the basis of a perpetual franchise, it will none the less be built, though the builders of the West try to profit by the mistakes of their fathers in the older States, and they usually succeed. Nevertheless, if any conservation policy seriously check development, Western sentiment will be found to set stubbornly against it.

A second sedulously cultivated opinion is that the conservation policies will result in exploiting the West for the benefit of the East, the latter having already recklessly wasted its own resources. There seems to us little merit in this contention, and if the first objection be met, if continued development be assured, we believe the West will be found solidly behind the President in his recommendation to Congress.

The forestry policy is settled. The change has produced some hardship and much irritation in the areas covered by the National Forests. We believe that there will be, as there should be, a decrease in the rigor of the administration of the forests, and that as the boundaries are rectified much of the friction

between the Forest Service and the public will disappear. The establishment of a leasing system for the public coal and oil lands should be easy, since coal and oil operators are generally accustomed to work on a royalty basis. The separation of surface from mineral rights is also but a return to first principles in much of the West, and will allow a prompt development of much ground which otherwise would long lie idle. The main contest will doubtless be in regard to power-sites and water-power. Public opinion regarding these is not well informed, and we believe that there is as yet no consensus as to what should be undertaken. On the whole, Mr. Taft has laid out a broad, consistent policy; one which deserves, as it will doubtless receive, general public support, and we believe that nowhere will support be more hearty or more sincere than in the West where there is most to gain or lose by conservation.

Recall of Mr. Crane.

The dismissal of a minister-designate before he had left the shores of his own country is a rare occurrence. It is spectacular, and humiliating for both the individual and the Government. Mr. Charles R. Crane had ventured to express opinions concerning the action of the United States in demanding and securing a portion of the Hankow-Sze-Chuen railroad loan, which was effected through the able instrumentality of Mr. Henry P. Fletcher, chargé d'affaires at Peking; and worse still he presumed to affirm a hostile attitude on the part of the Washington Government toward the recent treaty between Japan and China. Mr. Crane says in his defence that his utterance "contained nothing of substance that was not deducible by any competent newspaper reporter from facts commonly known," and he objects again that "I assumed the President wished me to discuss realities and not platitudes." Mr. Crane has further vindicated the action of Secretary Knox by these statements. Matters "deducible from facts commonly known" lack the force of an official announcement; it is as different as potential is from kinetic energy. Until time for the Government to act with the full force of national might it cannot sacrifice the value of veiled negotiation. President Taft wished the new minister to educate the people, but Mr. Crane seems to have assumed that educating them meant to inform them of the inner mysteries.

The mistake made was in going outside of the diplomatic service for the incumbent of a post where the utmost skill is needful. The Oriental situation is like a dynamite magazine; the least indiscretion may produce a disastrous explosion. No better trained diplomats exist than those gathered in the East, men who know the game in its finest subtleties. Several wise men declined the post; Mr. Crane would have been wiser had he followed their example; Mr. Knox may now show judgment in sending a man with the previous experience needful for so delicate a mission. The advantages of the growing commercial, mining, and manufacturing importance of the East may be gained to us by careful conduct of diplomatic relations; while a false step might hopelessly prejudice our opportunity.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

HOWARD D. SMITH is in London.

E. J. SWEETLAND has left Los Angeles for Mexico.

JAMES W. ABBOTT was recently at Salt Lake City.

H. S. KENNEY has sailed from Durban, Natal, for New York.

WILLIAM PORTER WISE, of Bisbee, Arizona, is visiting San Francisco.

PHILIP FOSTER is examining the Campo Morado, in Guerrero, Mexico.

C. W. PURINGTON will leave Nikolalevsk, Siberia, for London, October 20.

GEORGE WEBBERS, of the Robinson Deep, has been visiting at Berkeley, California.

R. C. RUCKER has arrived from Ecuador and will proceed to Johannesburg, South Africa.

D. E. SHERWOOD, formerly of Nevada, has opened an office in the Hooper Bdg., Salt Lake City.

F. H. MOFFIT, S. R. CAPPS, and ADOLPH KNOPF have returned to Washington from Alaska.

J. W. NESMITH visited several of the mills and smelting plants of Salt Lake valley last week.

C. W. WRIGHT is at Iglesias, in Sardinia, as consulting engineer to the Sociedad di Pertusola.

E. L. STENGER, recently testing engineer of the U. S. Geological Survey, is at Bellingham, Washington.

C. H. WRAY is examining the San Juan mine, Libertad district, Nicaragua, for the Oroya-Brownhill Company.

ROWLAND FEILDING, on his return from Siberia, went to Sweden to investigate the electric smelting of zinc-lead ores.

WILLIAM KIDNEY, of Montana, is superintendent of the new copper concentrating plant of the Ohio Copper Co. at Lark, Utah.

C. E. MORRIS, manager of the Santa Francisca mine, Department of León, Nicaragua, is returning to his post from a visit in London.

C. S. HERZIG is returning to Nicaragua from London. He will examine the Javalí and Escandalo mines, in which he may acquire an interest.

C. W. SAXMAN, formerly general manager for the Yampa Smelting Co., and the Tintic Mining & Development Co., has opened an office as consulting engineer at Salt Lake City.

EDWIN HIGGINS has resigned as assistant editor of *The Engineering & Mining Journal*, and will open an office as consulting engineer in the Central Bdg., Los Angeles, California.

T. R. DRUMMOND, former manager of the Newhouse properties in Beaver county, Utah, has taken the position of general manager for the Inspiration Copper Co., Globe, Arizona.

A. W. HUDSON has been transferred from the position of metallurgist of the Great Cobar, Ltd., New South Wales, to that of manager of the electrolytic and smelting plant of the same company at Lithgow.

Dividends to be paid shortly by three mining companies operating in the Goldfield district will amount to a total of \$1,263,000. Of this amount the Goldfield Consolidated Mines Co. will pay to its stockholders on October 31 the sum of approximately \$1,065,000, or 30c. per share; the Florence Goldfield Co. between October 25 and November 1 will distribute 10c. per share upon its outstanding stock, or \$105,000, and the Combination Fraction Mining Co. will pay a 10c. dividend, disbursing \$92,000 on November 5. A carefully compiled table of the profits paid by mines in the Goldfield mining district in five years, including those mentioned above, credits the camp with net profits of \$14,388,786. This does not include profits made by some of the leases operated by close corporations and does not take into ac-

count cash reserves now held by producing companies. The Consolidated will have in its treasury after the payment of the forthcoming dividend over \$2,000,000, the Florence and Combination Fraction each considerably more than \$100,000. Total payments by the three leading mines to November 1 are: Consolidated, \$3,901,624; Florence, \$630,000; and Fraction, \$92,000, on company account alone.

General Mining News.

ALASKA.

(Special Correspondence).—The Unuk River Mining & Dredging Co. is working a large force of men developing its quartz and placer properties on the Unuk river. J. W. Daley is manager.—D. B. Strong, representing Eastern capitalists, has secured an option on the Shellhouse and California group of claims on Dall island, off the west coast of Prince of Wales.—A freight barge is loading 2500 tons of ore from the Goodroe mine, Kasta bay. The ore is copper and gold, and is the first large shipment from this property.—The It, Mount Andrew, and Salzer mines are making regular shipments.

Ketchikan, October 1.

The gold medal for the best exhibit and photograph of gold-silver ore was awarded to the Alaska Perseverance Mining Co., operating the Alaska Perseverance mine, near Juneau.—Navigation on the Tanana river was closed by a sudden freezing of the stream. Several vessels were caught in the ice and will be held there till spring. A thousand tons of freight for Fairbanks has been tied up and will not arrive at its destination till next May.

ARIZONA.

COCHISE COUNTY.

Work has been started at the Black Queen property in the Paradise district which is under bond to Renwick White. The 263-ft. cross-cut will be advanced to intersect the limestone-felsite contact, on the surface of which considerable copper carbonate has been opened.—The Calumet & Arizona Mining Co. made the final payment of \$1750 on the April Fool claim in the Courtland district. The company has sunk a 500-ft. shaft on the property and is to install a heavy pumping plant while cross-cutting.—The smelter of the Wein Commercial company at Johnson was blown-in this week. H. S. Wein is manager.

GILA COUNTY.

The shaft at the property of the Cole Development Co., of Globe, has been unwatered and sinking resumed at the 320-ft. level. A vein of high-grade copper has been opened at the mine and several large bodies of concentrating ore. The Sullivan shaft, at the Cordova property, is down 500 ft., and cross-cutting started to open the ore found above.—The Miami extension of the Gila Valley railroad was completed to the site of the Miami Copper company's concentrator. The construction has been hurried, as a large amount of material for the concentrator has been sidetracked awaiting the building of this spur.—The Gibson Copper Co. is installing a power plant at its property in the Globe district.—The surface plant at the Superior & Boston company has been completed and the company will commence shipping ore by the first of the year.—The Black Warrior company is now shipping 110 tons of ore per day to the El Paso smelter. The Winnie shaft is being unwatered and sinking and cross-cutting will be resumed at the 250-ft. level.—The Ray Consolidated Copper Co. has expended \$125,000 lately in purchasing ground for a smelter site at Winkelman and has started a force of men clearing the land and grading for a spur to the railroad. The London-Gila Mining & Power Co., in the same district, has resumed work in its adit.

GRAHAM COUNTY.

The Archise Copper Co. has resumed operations at its property ten miles north of Safford in the Gila mountains.—Two Keystone drills arrived at Clifton on the way to the properties of the Copper Mines Co. of America. One drill will be placed on the Keystone, the other on the Celtic group.

MOHAVE COUNTY.

(Special Correspondence).—The Union Basin Mining Co., whose properties are situated in Union Basin district, has its main working shaft down 175 ft., and drifts started on the vein. The development planned is to sink the shaft to a depth of 600 ft., and cross-cut every 100 ft. The mine is

producing 10 tons of ore per day, which is shipped to the smelter at El Paso. A gravity tram has been completed to the wagon road, effecting a saving of \$1.50 per ton in transportation.—The 600-ft. shaft of the Elkhart mine, at Chloride, is to be re-timbered and sinking resumed. The underground workings, of which there are more than 1200 ft., are badly caved. These will be re-timbered and work resumed on the lead-silver ore. The last work done at the mine, before closing down a year ago, opened some carbonates of copper ore which will also be prospected.

Kingman, October 11.

PINAL COUNTY.

A good body of gold-silver ore has been opened recently on the Cloudburst claim of the old Silver King mine.

YAVAPAI COUNTY.

Two cross-cuts are being driven on the 700-ft. level of the Haynes property which joins the United Verde mine on the north. T. E. Campbell is manager.—By paying \$8000 to Fred W. Williams, H. J. Beemer completed the installments of his \$58,000 option on the Storm Cloud mine, 12 miles south of Prescott. The main development is a 1200-ft. drift on the Storm Cloud vein exposing a copper-gold ore that assays from \$25 to \$40 per ton. There are 15 claims in the group, and several shipments to the Humboldt smelter, more than covered the cost of mining and shipping. As soon as this smelter resumes operations shipments will be forwarded from the mine.—The shaft at the Monroe mine near Huron has been stopped at a depth of 170 ft., and drifts started on a vein of black oxide copper ore. Several shipments have been made to the smelter at Needles. C. P. Wingfield is the owner of the property.—The Peacock Mining Co., operating ten miles south of Prescott, has let a contract to sink its shaft 800 ft. This will make a total depth of 1025 ft.—The 300-ft. shaft at the Marcus mine, in the Weaver mountains, has been unwatered by T. J. Morrison, and a body of sulphide ore opened. The ore from the upper levels of the mine was worked in early days by an arrastre for its gold and silver content and several shipments made to the smelter.—At the property of the Golden Ridge Mining & Milling Co., the vein is 10 ft. wide, and assays \$8 per ton. Eli S. Perkins is manager.

YUMA COUNTY.

The cross-cut adit at the Harcuver Copper Co.'s property in the Cunningham Pass district is in 325 ft. and is expected to cut the ore within the next 100 ft., giving a vertical depth of 270 ft. An official survey has been made of the claims, and application for a patent will be made some time this month.—A body of high-grade copper ore was cut on the 100-ft. level of the Little Butte mine at Bouse. The shaft is now down 275 ft., and will be continued to the 500-ft. level with cross-cuts to the orebody at the 300.

CALIFORNIA.

NEVADA COUNTY.

New machinery is to be installed, a surface plant constructed, and work resumed at the Yuba mine, near Maybert, which is owned by the Yuba Gold Mining Co.—The 30-stamp mill at the Erie mine, near Graniteville, is to be started this month. R. G. Eckis is manager.

SHASTA COUNTY.

The Stauffer Chemical Co. has taken a \$10,000 bond on the Oro Fino mine near Shasta. The bond runs for one year, and it is the intention of the company to erect a 5-stamp mill on the property.—The Mammoth Mining Co. is to sink the double-compartment shaft at the Quartz Hill mine an additional 100 ft., making a total depth of 273 feet.

SIERRA COUNTY.

The cross-cut at the Bunker Hill mine, near Downieville, under bond to Breese & Hood, opened the channel. No driving has been done, so the extent of the find is unknown.—The company operating the Kate Hardy mine, near Forest, is opening a 20-ft. vein of high-grade milling ore. It is probable that a mill will be erected in the spring.—A small furnace has been built to roast the sulphide concentrate at the Sailor Ravine mine, in the Downieville district, operated by Frye & Winrod.

SISKIYOU COUNTY.

The Yellow Butte Mining Co., operating east of Weed, has been re-organized, and work will be resumed at the property.

TUOLUMNE COUNTY.

An 18-in. vein has been cut near the surface in the Keltz mine.—The cross-cut on the 300-ft. level of the Black Oak property opened a 3-ft. vein of shipping ore.—It was stated by Bert Clark that the shaft on the Clark Brothers' ranch, in the Sonora district, is down 40 ft. on a 3-ft. vein, 6 in. of which is good shipping ore. A horse-whim is to be installed and the shaft sunk to the 100-ft. level before any lateral work is started.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—An important mining deal was closed last Saturday in the office of the Boyce-Mouat Engineering Co., Denver, when the Bellevue-Hudson group of 14 lode mining claims, tunnel and mill-sites was purchased by the Southwestern Mines Corporation, of Boston, for a reported consideration of \$150,000. M. W. Mouat, the Colorado manager, states that the Bellevue-Rochester adit, which is known as the ninth level, will be advanced at once 5600 ft. This will intersect the Dictator, Mogul, Prince Albert, Kohinoor, Drummond, American Sisters, Jo Reynolds, and Lamartine veins, the combined production of which exceeds \$9,000,000. A winze is to be sunk 400 ft. from the ninth level, and cross-cuts driven from each 100-ft. station. This will put the heading of the lower workings under the ore-shoots on the Anampsa vein. A 100-ton concentrating plant and 10-drill compressor will be installed, the equipment having been ordered from the Colorado Machinery & Supply Co., of Denver. With the shaft sunk the proposed depth of 400 ft., the Bellevue-Hudson will be the deepest worked mine in the silver-lead district of Clear Creek county.—A promising find was made last week in the Golden Glory adit at Saxon mountain, when in 610 ft. A streak of mixed ore and quartz was cut that is from 6 to 8 in. wide. H. A. Shipman is consulting engineer. An electric hoist is being installed at the bottom of the raise in the Scepter adit on Democrat mountain that is being put through to connect with the Sunburst workings above, and will be used to hoist timbers. A. B. Montgomery, of Denver, is manager.—Work has been started advancing the sixth level of the Mineral Chief property, and a body of milling ore is being followed that is from 6 to 9 ft. wide. Within two weeks it is expected to have the connection made between levels No. 6 and 5, at which time shipments of smelting ore will be started. C. E. Pughe is manager.—The Crescent 20-ton concentrating plant is to be started on day and night shifts during the present week. During the last two months development has been under way at the New Boston mine, and ample material is now available to insure a continuous supply. The vein of lead-zinc ore measures from 5 to 6 ft. across, and the ground is opened 150 ft.—B. J. Martelon, manager for the Argentine Exploration Co., operating the Mammoth mine on Sherman mountain, is shipping ore to the Mendota mill. The aerial tramway is in good condition and the output will be increased to 50 tons per day by the end of the month. The Black Prince adit, on Pendleton mountain, has intersected another vein, which is supposed to be the extension of the Ontario. Frank Winters is manager.

Georgetown, October 9.

LAKE COUNTY.

The Progressive property, in the Leadville district, has been unwatered and a cross-cut started from the bottom of the 300-ft. shaft to cut the ore. A year ago lessees opened a vein that ran 50% lead, 325 oz. silver, and \$1 gold per ton, but were forced to abandon the work on account of poor financial condition. Howard B. Collins is manager.—George Champion and associates, operating the Little Bob property under lease, are prospecting to find the extension of the shoot recently cut by the St. Louis adit.—The Little Evelyn Mining Co. is shipping 20 tons per day from its lease on Breece hill. Drifts are now being run on a vein cut by the 200-ft. winze from the adit level.

SUMMIT COUNTY.

Arrangements are being made by Mr. Detwiler and associates, of Breckenridge, to resume operations at the C. & S. property on the upper Blue river.—The Continental Chief Mining Co. and the Mint Mining & Milling Co. have consolidated and will operate under the name of Ophir Mountain Consolidated Mines Co. The properties are two miles south of Frisco, and have been opened by about 1300 ft. of development. Conrad Henneck, of Frisco, is superintendent.

TELLER COUNTY.

The return on 24 tons shipped by Joseph Brentlinger and associates from the property of the Old Gold Mines Co., on Beacon hill, amounted to \$52 per ton.—John Wood, of Cripple Creek, has secured a two years' lease on the K. P. claim of the Western Union Mines Co. on a royalty of 10% the first year and 15% of the value of the ore marketed the second year. There are 10 acres in the claim and several bodies of low-grade ore have been opened.—The United Gold Mines Co. has given L. S. Cox a lease on the Damon property for two years.—P. E. Murcay is shipping six cars of ore per month that averages \$50 per ton from a sub-lease on the Anchoria-Leland property on Gold hill.—The Vindicator Consolidated Gold Mining Co. declared the regular quarterly dividend of 3c. per share payable October 25. The total amount distributed will be \$45,000.—The September output from the main shaft of the Mary McKinney Mining Co. was 725 tons of \$25 ore. Lessees on other portions of the estate shipped 1500 tons of milling ore.—A new steam hoist is being installed at the Nightingale claim by Milhoun & Mart, who are operating the property under lease from the Stratton company.

IDAHO.

BLAINE COUNTY.

George Z. Edwards has been forced to resign his position as manager of the Cannon Ball mine, 35 miles west of Hailey, on account of several attempts to take his life. Mr. Edwards was formerly superintendent of the Mercur mine in Utah and of the Lincoln mine at Pearl, Idaho, and is considered an efficient manager.

IDAHO COUNTY.

Contracts have been let to double the capacity of the 10-stamp mill at the Crackerjack mine in the Buffalo Hump district. The Crackerjack company is operating on a 30-ft. vein that mills \$6 per ton, the cost of mining and milling approximating \$3 per ton.

OWYHEE COUNTY.

An 8-ft. vein of rich ore has been opened on the Como and Alice No. 2 claims in the Silver City district by Connors & Belcher.—The drift at the Banner property is being driven on a 4-ft. vein and is expected to tap the ore-shoot shortly.—Considerable new electric equipment is being installed at the Rich Gulch mine near Silver City. A. F. Stevens is manager.

KANSAS.

CHEROKEE COUNTY.

(Special Correspondence).—The Herald Mining Co. is sinking a 300-ft. drill-hole. The drill entered ore at 139 ft., and is still in ore at 230 ft. A drift from the shaft has been started in the direction of the new find.—The Ihlsing shaft is down 260 ft. and will be continued to about 300 ft. The ore was reached at 227 ft. Two mills will be built, one on the Ping and the second on the Robertson land.—Oscar De Graff has made a rich discovery on his 360-acre farm near the Badger-Peacock, the drill cutting ore at 150 ft. A contract will be let for a mill in the near future.—Childress Bros., operating in Galena, have secured a new 4-lot lease and will build a mill on the property. The company already operates two plants on well developed leases. Galena, October 11.

MISSOURI.

JASPER COUNTY.

(Special Correspondence).—The Nashville Tennessee Co., in East hollow, has resumed operations and two of the old drifts have been re-opened. A face 20 ft. high has been disclosed in one, while a face 12 ft. high has been found

in the other.—In the Zincite camp, the old General mine has begun operation again, and is shipping a high-grade concentrate.—The White Swan Co., in the same camp, has just completed a large new mill.—L. A. Cunningham has resumed work at the old Lucky Jim property. The ore is found at a depth of 175 ft.—The B. & C. mine, which has not been worked for several years, is again being operated and a new shaft north of the mill is being sunk.—Mill No. 3, of the Oronogo Circle Co., at Oronogo, has resumed operation after the damage done by fire a few weeks ago was repaired.—One of the richest discoveries made for some time is a lead find on the Murphy land where the ore has been found in bore-holes from 175 to 200 ft.—At the Ino property a new rich orebody was cut in a shaft northwest of the present one at a depth of 135 ft., the ore running 20% zinc. The old Dominion mill will be re-fitted to treat the ore.—Edwards & Schnur have found ore in the third drill-hole sunk on their lease on the Rex land. The deposit is from 58 to 75 ft.—Rich ore has been found in a drill-hole from 80 to 86 ft. on the Pinkard land.—A rich run of galena and blende was cut west of Sarcosie by the shaft on the Rohrer land at a depth of 35 ft.—The new Columbus mill, near the old Bumble Bee mine, southeast of Joplin, is now producing 5 tons of high-grade concentrate per day. The ore occurs at a depth of 142 ft.—The Durby Mining Co., at Prosperity, is to erect a 200-ton mill on the lease of the Ground & Irwin tract.—Gallagher & Gerke are to build a new mill west of Joplin on the sheet ground area. From the shaft 100 ft. of driving has been done already. Thirteen drill-holes have been sunk on the land, opening a uniform deposit which will mill 6% zinc blende.

Joplin, October 9.

NEW MEXICO.

SIERRA COUNTY.

(Special Correspondence).—The Black Range and Apache districts in this county are again coming into prominence after many years of inactivity. Eastern and Colorado capi-

Map of New Mexico.

talists are principally interested and have developed several promising claims. The principal towns of the district are Chloride, Fairview, and Fluorine. The district is reached by stage from Engle on the El Paso branch of the Santa Fe.—A vein of ore assaying from \$60 to \$2500 per ton has been opened at a depth of 145 ft. in the United States Treasury mine. Considerable low-grade ore is being opened in the White Eagle shaft. A boiler, hoist, compressor, and pump were recently installed at this shaft. The company expects to build a mill in the near future.—Ohio capitalists have purchased 100 acres of land lying

near the United States Treasury group. Operations will be commenced soon.—At the Great Republic a 3-ft. vein assaying \$60 per ton gold and silver has been opened by a cross-cut from the shaft. Frank P. Davis is manager.—The Home Mining Co. is installing a Chilean mill.

Chloride, September 30.

NEVADA.

ESMERALDA COUNTY.

The Florence Goldfield Mining Co. has declared a dividend of 10c. per share, payable November 1, the total amounting to \$105,000.—A dividend of 10% amounting to \$93,000, was declared by the Combination Fraction Mining Co., of Goldfield. The company is mining approximately \$50,000 worth of ore per month, and will have over \$100,000 surplus left in the treasury after the dividend is paid.—The cross-cut from the raise on the 730-ft. level of the Mohawk workings of the Consolidated company opened a body of ore that assays from \$1200 to \$1800 per ton. Six 7-ft. Chilean mills are to be added to the Consolidated mill to handle the increased output from the lower workings. The company is to distribute \$1,065,000 dividends on October 31.—The Precious Metals Mining & Milling Co., of Nevada, operating in the Goldfield district, has adopted the policy of having its stock assessable. This is the first company in the district to take this method of financing the development. Many of the companies in Nevada have been handicapped by lack of funds to carry on prospecting and their properties have lain idle.—A shipment of 12 tons was made to the Nevada-Goldfield Reduction Works from the Kansas City Velvet lease, on the old Truitt shaft. The ore assays from \$75 to \$150 per ton.—The Burke lease, on the Belmont property, at Diamondfield, is shipping ore to the sampler that assays from \$150 to \$300 per ton. The cross-cut on the 200-ft. level recently opened a body of ore in which some of the high-grade streaks assay as high as \$3000 per ton.—The Oriole Mining Co., with mines near Mina, has just bought a stamp-mill, power equipment, compressor, and drills. The ore to be treated consists of a free-milling porphyry, and it is expected that no cyanide plant will be required.

NYE COUNTY.

(Special Correspondence).—It is reported that high-grade ore has been struck on the 150 and 330-ft. levels of the Pioneer lease.—Clothier & Gingles recently shipped 41 tons of \$73 ore to Goldfield. The lease is operating on the Denver claim of Tramps Consolidated. The semi-monthly clean-up of the Montgomery-Shoshone mill amounted to approximately \$18,000.—The entire estate of the Bullfrog Extension Mining Co. has been leased to Goldfield people. The Red Star Mining Co. will open the west portion of the Delaware claim, where a 40-ft. body of low-grade ore has been cut at a depth of 125 ft. The east portion of the claim and the Last Chance claim will be worked by the Black Duck and Green Ore Mining & Leasing companies. The 250-ft. shaft will be sunk to the 500-ft. point.—It is reported that the chief stockholders of the West Extension have notified the creditors that all bills will be met as soon as proved.—The extraction from the Manhattan placers is daily increasing. One company has opened excellent gravel in one of the branch benches, which is thought to prove the mineralized district for a considerable distance outside the main gulch.—The Goldfield-Bald Mountain company is in control of the largest acreage in camp, and is employing 24 men. A large portion of the ground has been blocked out and production will soon commence.—The Breyfogle Mines Co. is opening a bed of gravel at a depth of 20 ft. The gravel is 3 ft. thick and runs \$7 to \$8 per cu. yd. An electric hoist and centrifugal pump will be installed.

Rhyolite, October 8.

STOREY COUNTY.

(Special Correspondence).—A vein of gold-silver ore, said to be over 4 ft. wide, with assays from \$50 to \$130 per ton, has been cut by the drift from the 2300-ft. level of the Mexican.—Several lessees have started work on the Ophir and Best & Belcher ground.—On Crown Point a south drift is being driven from the 1100-ft. level. About 250 tons per week of milling ore is being mined on the upper levels and sent

to the Yellow Jacket mill, which is handling from 700 to 800 tons of low-grade ore per week.—At the Overman the No. 3 cross-cut from the north drift on the 1200-ft. level is opening a small quartz vein in unprospected ground.—The joint drift, being extended easterly by the Ophir and Consolidated Virginia companies, is making good progress, and is expected to cut the vein soon. The output of Ophir has fallen materially during the past two months, but the grade is improving, and the management expects to increase the tonnage in the near future.—A one-half interest in the Baker claim, on the Brunswick lode, has been sold to Robert Ingalls, of Olinghouse. The reputed price is \$130,000, \$30,000 cash, to be paid within a year, and the balance expended in development. A force of men will be immediately placed at work.—Despite the handicapping of work, and damage to machinery by the boiling water struck in the Ward shaft, operations are progressing rapidly. The rise of the water has been effectively checked, and the pumps are working well.

Virginia City, October 9.

TEXAS.

BREWSTER COUNTY.

(Special Correspondence).—The proved cinnabar district in the southern part of this county, adjacent to the Mexican border, has been enlarged by the recent discovery of rich cinnabar ore in the mountains about 30 miles north of Boquillas. The discovery was made by a Mexican goat herder who took samples of the ore to the town of Boquillas where it attracted the attention of miners. Thomas Locke and associates of San Antonio purchased the claim

Terlingua Quicksilver District.

and are preparing to develop the property. The scene of the new discovery is about 50 miles east of Terlingua, the chief quicksilver camp of that region.

Terlingua, October 9.

EL PASO COUNTY.

(Special Correspondence).—The El Paso Tin Mining & Smelting Company, which was recently organized with a capital stock of \$700,000, one-half of which is already paid in, has acquired a large tract of mineral land in the Franklin mountains, and is arranging to develop its holdings on a large scale. A large body of tin ore outcrops on the property, near Mundy springs, and the company will install machinery and sink a shaft to prospect the ground. It is claimed that several hundred thousand dollars worth of ore is in sight. It is planned by the company to erect a tin smelter when the property is sufficiently developed to justify that improvement. The discovery of tin ore in the Franklin mountains was made in 1899. According to the report of mining engineers who examined the property, the ore is cassiterite, associated with quartz veins in the granite at the eastern base of the range. The tin veins occur along joints in the granite and dip perpendicularly or at high angles with an east and west strike.

El Paso, October 11.

PRESIDIO COUNTY.

(Special Correspondence).—John T. Fredley will erect a stamp-mill at his silver mine in the Clenega mountains, about ten miles west of Shafter, where the famous Shafter silver mine is situated. A number of good claims have been located in that district recently and the prospects of considerable mineral development are considered promising.

Shafter, October 9.

UTAH.

JUAB COUNTY.

The lower levels of the Raymond-Illinois mine, at Eureka, are to be explored with diamond-drills. The company is now working on the 1500-ft. level and expects to drill 500 ft. below this.—The Uncle Sam Mining Co., of Tintic, declared a dividend of 2c. per share, amounting to \$10,000.

SALT LAKE COUNTY.

The annual report of the Utah-Apex Mining Co. gave the number of tons mined as 33,407, the cost per ton of mining being \$2.47. Milling costs were \$1.37, smelting of first-class, \$5.71, concentrate, \$3.63, and freight on the material shipped, 83c. per ton. The profit for the year amounted to \$124,185, and in the mine there is approximately 80,000 tons of ore blocked out.

SUMMIT COUNTY.

The company operating the Silver Bell mine, in Thaynes canyon, near Park City, has been re-organized, and operations will be resumed at the mine, after a shut-down of four years. Anton Pederson is president of the company.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—The New Republic Co. has installed a motor on Granite creek, to pump water to the Republic mine. The pump has been replaced in the winze, below the 600-ft. level, and the hoisting engine at the head of the winze has been connected with the electric plant at the portal of the No. 3 adit. The winze has been unwatered to a depth of 90 ft., and mining operations will be resumed on the 700-ft. level as soon as the drainage is completed. On September 22 a carload of sacked ore was shipped to the Tacoma smelter, which averaged about \$200 per ton. At the same time a bulk carload was shipped, which ran from \$65 to \$70 per ton. The company is now shipping 200 tons per week. Since the Republic mine was leased to the company, the smelter returns filed with the Ferry county auditor show that ore has been shipped which assayed 35.85 oz. gold and 784.2 oz. silver per ton. This rich ore amounted to 244 lb. and was sent to the Trail smelter. One shipment of 199 tons to the Tacoma smelter contained 19.5 oz. gold and 51.3 oz. silver per ton. Freight and treatments at the Granby smelter amounted to \$6.75 per ton. The following monthly shipments since January 1, 1909, have been certified to the Ferry county auditor:

BY THE GRANBY SMELTER.

| Month. | Dry Wt. lb. | Total Gross Value. | Total Net Value. |
|---------------|-------------|--------------------|------------------|
| January | 102,996 | \$ 3,551.32 | \$ 3,119.86 |
| February | 240,242 | 3,030.81 | 2,209.12 |

BY THE TACOMA SMELTER.

| | | | |
|--------------|---------|-------------|-------------|
| February ... | 81,663 | \$ 8,424.31 | \$ 7,958.10 |
| March | 111,888 | 704.89 | 176.21 |
| April | 436,152 | 10,574.73 | 8,350.57 |
| May | 534,284 | 14,801.62 | 12,104.63 |
| June | 586,261 | 14,850.57 | 11,871.12 |
| July | 786,459 | 17,076.80 | 12,981.66 |
| August | 606,678 | 11,130.31 | 8,040.62 |

Total 3,489,623 \$84,145.36 \$66,811.89

The Jim Clark adit, at the Pearl Consolidated, has been driven 30 ft. on the No. 4 Lone Pine vein, which was 20 in. wide when first cut, and is 3 ft. wide at the breast. The ore across the vein runs about \$50 per ton, and samples have assayed as high as \$370 gold per ton.—The adit of the Hercules mine, at Park City, now in 331 ft., is to be extended 300 ft. to drive it under the cropping of the vein, at a depth of 250 ft. The cropping is rich silver-copper ore and about 10 ft. wide. A rich strike is reported from the Sunrise mine, at Danville, samples of ore from which are reported to assay from \$3000 to \$4000 per ton.—About 200 ft. from the portal of the adit at the Jennie mine, near Rockcut, a winze is down 25 ft. on three stringers of copper and galena ore.—The shaft of the Kettle River mine, at Rockcut, is down 143 ft., and the company has decided

upon the showing made, to install a concentrating plant. The mine is equipped with a steam hoist, air-compressor, and machine-drills.—The Summit Gold & Copper Mining Co. is advertising for bids to sink the upper shaft on the Railroad group 50 ft., and to sink the Summit winze 50 ft., with the privilege of 50 ft. additional at each place.

Republic, October 11.

CANADA.

BRITISH COLUMBIA.

(Special Correspondence).—The Velvet-Portland mine, west of Rossland, has been leased to Ed. Ehrenberg, of Spokane, by an English syndicate. It is equipped with a concentrator and compressor plant and is opened to a depth of over 400 ft., the ore assaying from \$20 to \$40 per ton gold, silver, and copper. The opening of this property seems to assure the resumption of work at the Le Roi smelter at Northport in the not distant future, which means that the Le Roi will then begin shipping.—At the meeting of the Consolidated Mining & Smelting Co., of Canada, Ltd., to be held in Toronto, October 12, the directors considered a proposition to increase the capital of the company from \$5,500,000 to \$7,500,000. As the company has adopted a big expansive policy, it has been found necessary to seriously consider this step.—Hugh Harris, and associates of Rossland, have bonded the group of claims owned by them at Nine-Mile mountain, near Hazelton, to W. L. Somerville, for two years for \$60,000. The property is a rich silver-lead group and it is planned to begin shipping next spring, by boat from Hazelton.—Mining operations are lively in the Sheep Creek district. A bond has been taken on the Searchlight group, which adjoins the Mother Lode and the Bayonne, which has been held at a high figure by its Butte owners, has been bonded to a New York operator who has also taken over the Clyde-Belt group and the Kennedy.

The West Kootenay Power & Light Co., of Rossland, will run a power line into the Sheep Creek mines and supply power to that district, the average charge being \$32 per hp. per annum.—At the Mother Lode mine, in the Nelson district, now being operated by John McMartin, an engineer is surveying sites for a new stamp-mill and surface plant. The recent find in the lower adit of this property is giving excellent results as work is continued.—At the Nugget mine a 4-ft. vein of good ore has been cut on the fourth level during the past week.—The head-frame at the Silver King mine, near Nelson, has been repaired and shipping will be resumed during the coming week.

The Alma M. mineral claim, 8 miles from Nelson, has been bonded by J. T. Hillis, of Vancouver, and S. S. Raymond, for \$45,000.

The Van-Roi Mining Co. will soon make the last payment on the Vancouver group near Silverton. This property was bonded several years ago by the Le Roi 2, Ltd., and turned over to the new company. Of the purchase price, which is \$150,000, most of the money has been derived from the product of the mine itself.—The lessees of the Ottawa shipped 34 tons of ore the past week.—A car of ore was shipped across Moyle lake from Aurora mine last week.

Ten thousand acres of coal land have recently been acquired in the Peace river district by eastern Canadian capitalists. The coal, which has been found in rich deposits, is said to be a good coking and domestic coal.—The Oro Denoro mine, of the British Columbia Copper Co., near Phoenix, shipped 300 tons last week. The Sally also shipped 22 tons of high-grade ore. Shipments from the Mother Lode amounted to 1000 tons last week. The Greenwood smelter, where No. 3 furnace has been blown in to treat the increased Mother Lode as well as the Oro Denoro shipments, received 8800 tons of ore.—It is now announced that the B. C. Copper Co. will not begin diamond-drill exploration this year on the recently bonded groups of claims in Kamloops. The change of plans has been caused by the recent agreement to work the mines and treat the ore of the New Dominion Copper Co.—The seventh enlarged furnace was blown in at the Granby smelter last week. The last one will be put in operation on October 10, when shipments from the mine will be slightly increased.—An English syndicate has bought 3520 acres of coal land on Granite creek for the sum of \$200,000 from the Tulameen Coal & Coke Co. The

property is 11 miles from Princeton and near the V. V. & E. railway.—An explosion of gas in the Extension mine, of the Wellington Colliery Co., killed 28 men. The explosion started a fire in the mine and it was with great difficulty that the bodies of the miners were recovered.

Rossland, October 9.

MEXICO.

CHIHUAHUA.

The Porvenir Mining Co., operating in the Parral district, has been re-organized under the name Corona Consolidated Mining & Milling Co. The stock of the company has been reduced and the management plans to erect a mill this winter. Nat P. Wilson is manager.—A large number of the stockholders of the Alvarado Consolidated Mines Co. visited the properties of the company in the Parral district the first of the month. The plans for the new mill were approved and contracts for machinery and supplies are being let. James I. Long is manager.—The Lustre Mining & Smelting Co., operating near Parral, is being re-organized and will soon be in a position to settle all financial obligations. R. W. Bissell is in charge of the property.—The Cordero Mines Co., operating the Soledad property at Cordero under lease, shipped a carload of ore last month that assayed 40% lead and 4 kg. silver per ton and expects to ship four carloads of similar ore this month. There are a number of old mines at Cordero, which is 35 miles from Parral, that have produced well in the past, and the prospects for the revival of interest in the mines of that district are excellent.

JALISCO.

The Tajo Mining Co., which recently erected a cyanide plant at its mines in the district of San Sebastian, sent the results of the first clean-up, consisting of 604 lb. of precipitate to the National Metal Co. in Mexico City. This produced about \$10,000. The plant has a capacity of 30 tons per day, and the extraction is said to be as high as 90%. Robert H. Lilly is in charge of operations.

OAXACA.

The 5-stamp mill of the Rio Seco Mining Co., at El Parian, will be in operation in about six weeks. The plant is experimental and a larger one will be erected later on.—The El Placer mine and mill, situated a few miles from Oaxaca, operated by the Boston & Oaxaca Mining Co., were sold at auction on September 29. According to information received from the local management, internal dissensions in the company have made this course necessary.—A stamp-mill has been installed at the El Socorro mine and another at the Old Mexico mines, in Sierra Juarez.—The San Juan mine, in the Taviche district, is being sampled by Denny Bros., who have an option on the property. The price is said to be \$500,000.

SONORA.

If the present plans of the Cole-Ryan interests are carried out their relation with Phelps, Dodge & Co. will be closer than ever. The Indiana-Sonora and other properties in that district will be turned over to the Cole-Ryan people through the Greene company. It is also probable that the Greene company will build a railroad to connect with the Phelps-Dodge line if a more favorable rate cannot be obtained from the Southern Pacific. If this road is built, it is likely that they will raise the necessary money by a new stock issue.—Three Tremain steam stamps have recently been installed by the Candelerio Mining Co. on its mine at La Barranca. The mill has now been in operation for a month, and the superintendent, S. Ben Smith, reports a capacity of 16 tons per twin unit, crushed through 30-mesh in 24 hours.

SALVADOR.

Gonzales & Vides are building a mill and cyanide plant on their property on El Mineral Comacarán. The foundations and buildings are being erected and although the machinery has been shipped from Chicago, its transportation from La Unión to the mine cannot be undertaken until after the rainy season. The plant, though small, is complete in every detail, and includes a Blake crusher, Allis-Chalmers stamps, vacuum filter, tube-mill, and air-agitator, while all tanks are built of steel plate.

Special Correspondence.

SALT LAKE, UTAH.

American Institute Visit. — September Copper Production. — International Ore Supply. — Boston Con. Ore Contract. — Lewisohn Interests.

The feature of the week here has been the visit of the American Institute of Mining Engineers. The party, after a pleasant day at Tacoma, and a disappointing one at Portland, arrived Wednesday. Three days were spent inspecting local mines, mills, and smelting plants. The visitors were met on arrival, October 7, by a committee of local members including R. H. Bradford, Ellsworth Daggett, Robert Forrester, Samuel Newhouse, D. C. Jackling, L. Hanchett, J. C. Dick, R. C. Gemmell, L. S. Cates, E. P. Jennings, C. W. Saxman, B. F. Tibby, J. B. Risque, Thomas

stamp-mill is doing the work and the separation accomplished on the Wilfley tables and Johnson vanners is up to expectations. The Boston Consolidated was especially frank in giving information and inviting criticism and distributed a pamphlet giving in great detail the costs for the month of September. On Saturday the visitors were the guests of the Utah Society of Engineers for a trolley-car ride about the city in the morning, and in the afternoon made an excursion to Saltair; Saturday night the visitors left for Colorado.

Utah mines produced, approximately, 10,500,000 lb. of copper during September. The Bingham production increased considerably. Utah Copper made a new high record, producing over half the total. The Coppertown plant has been brought up to a capacity of 1000 tons per day, while the Garfield mill is handling something in excess of 6000 tons. D. C. Jackling, general manager, has recommended the addition of 3000 tons to the present plant, and if conditions in the metal market are favorable, this work may be started by April of next year.

Map of Utah.

Bingham Canyon.

Weir, C. E. Allen, G. W. Metcalf, S. R. Woodbridge, C. W. Whitley, George W. Heintz, P. E. Barbour, George D. Blood, E. W. Durfee, George W. Riter, John Dern, A. J. Bettles.

The special train was taken at once to Bingham Canyon, the town which has been described as two miles long, fifty feet wide, and eighteen inches deep—the last referring to the mud in the single street. However, the engineering features of the canyon soon attracted attention away from the town itself. The only mine inspected in detail was the great open-cut working of the Utah Copper Co., which was examined with much interest. After luncheon on the train, when the members of the local committee were the guests of the visitors, stops were made at the smelters at Bingham and Murray. In the evening, after the return to Salt Lake, the visitors were entertained by an organ recital in the Mormon Tabernacle. Friday was devoted to visiting the smelter of the American Smelters Securities Co., the concentrating mills of the Boston Consolidated Co., and the Utah Copper Co., all at Garfield, and the mill and smelter, under construction, of the International company at Tooele. At the mills of the Boston Consolidated and the Utah Copper Co., an excellent opportunity was afforded to study two different methods of treatment of the same character of ore. The Boston Consolidated mill is equipped with Nissen stamps, and the Utah plant is equipped with Chilean mills. At the time the Utah mill was constructed it was not believed that the ores could be successfully treated by stamps, but the

Work at the International smelting plant, near Pine canyon, is being rushed, and E. P. Mathewson, general manager, says that less delay in the delivery of material has occurred than was anticipated. Both day and night forces are being employed, and some of the steel structures are now completed. Brick work is going forward. The foundation of the great stack, which is to be 350 ft. high, is in, and 10 ft. of the base of the stack is up. Originally the plant was designed for treating 2000 tons of ore per day. Since the Cole-Ryan interests have failed to obtain contracts for the treatment of the Tintic ores, plans have been changed. The plant will only be built to treat 1000 to 1200 tons of the Utah Consolidated output for the present. The company will be in the market for other ores and as fast as conditions justify, the capacity will be increased. Ohio Copper and other producers that have not entered into long contracts with the American and United States companies, are expected to close contracts with the International. It is also understood that the Boston Consolidated is not satisfied with its existing contract with the Garfield plant, and has been dickering with the Cole-Ryan people. The split between the Boston Consolidated and the Garfield company dates back several years. When the Utah Copper, Boston Consolidated, and American Smelters Securities companies entered into an agreement to take up a large tract of land along the shores of Great Salt Lake, they were to have a community interest in the ground which constituted the

site for the smelter, two mills, and a town for the employees. After the transfer of the property had been made to a joint company and water rights secured, Samuel Newhouse became dissatisfied with the contract made for the smelting of the Boston ores. After numerous conferences with the Guggenheims in New York, a modified contract was substituted. Everything went well for a time, but since the International has entered the field it is apparent that the Boston people are after a further reduction in treatment charges. The Boston is producing in the neighborhood of 2,000,000 lb. of copper per month, and should this ore be withdrawn from the Garfield plant at the same time the Utah Consolidated diverts its ores to the International, it would seriously cripple the Garfield furnaces. These are now treating upward of 3500 tons of copper ore daily.

The first section of the Ohio Copper mill will be in operation within 60 days, provided no unforeseen interruptions occur. Colin McIntosh, general manager, is confident that the entire mill will be running within six months. He expects a high saving and to be able to produce at less than 8c. per lb. The rumors connecting the name of the Cole-Ryan syndicate with control of Ohio Copper have ceased. Recently a prominent engineer of the Lewisohn staff has been here and it is said that the object of his trip was to inspect Ohio Copper properties. The Salt Lake copper ground owned by the Lewisohns has caved badly, and they have discontinued operations. The output for the past month is only half the normal production, and they now intend to turn the property over to lessees. The management will not say what action the owners are going to take regarding future operations, as it has not finally been decided what course to pursue. These conditions have resulted in a rumor that the Lewisohns intend to get another copper producer in Utah. F. Augustus Heinze states that the control of Ohio Copper has passed from his hands. The fact that the new owners have been unable to finance the proposition leads to the belief that the property is still in the market.

NEW YORK.

Cumberland-Ely Again.—Copper Corporation Forming. — Toulumne Copper Advances.—Batopilas Financed.—Camp Morado.

Last week mention was made of the probable consolidation of Cumberland-Ely and Nevada Consolidated. Cumberland-Ely has continued to be something of a market factor during the week, but some are inclined to credit the buying rather to the Cole-Ryan interests than to the Guggenheims. It is now stated that during the recent liquidation of the Thompson holdings in Cumberland-Ely no small part of the stock was taken by Mr. Cole and his associates. In fact, this move is said to be part of a big program for a copper combine, to be modeled closely after the lines of the United States Steel Corporation. Several considerations would tend to make a controlling interest in Cumberland-Ely peculiarly valuable to the Cole-Ryan people. They have recently acquired the Giroux, and several surrounding properties. The Giroux must have a smelter and transportation facilities. Cumberland-Ely has a three-eighths interest in the Steptoe smelter and a half interest in the Nevada Northern railway. A welding of these interests with the Giroux would give the owners a commanding place in the Ely camp. While no definite admissions can be obtained as to the deal between the Cole-Ryan interests and Phelps, Dodge & Co., it is undoubtedly true that negotiations are under way whereby the former are to get some of the minor properties of the latter, including the Moctezuma and probably the Detroit. These are to become part of a consolidation of Mexican properties with the Greene-Cananea at the head for the present. The Hovland & Smith properties, at Globe, lying adjacent to the Miami, also have passed to the Cole-Ryan interests. In view of these purchases it is not surprising that rumors are heard of a company to hold some such place in copper as the Steel Corporation holds in its domain. Although the Amalgamated Copper Co., as a corporation, has made no move outside of Butte so far, yet its weight doubtless will be thrown into such a consolidation the moment plans are sufficiently matured.

Marketwise, the feature of the Street for the week was the rise in Toulumne Copper. The stock has moved up from \$2.50 to \$4.50 and it is noted as the most important market advance in the Street for several months for the reason that there has been an absolute freedom from manipulation. The market has been very strong and it would appear that further advances are to be expected. Ely Central has absorbed a large share of the attention of the traders. A report made on the company's ground at Ely, is favorable, and a strong advertising campaign has carried the stock to a level of \$1.50.

A contract has been made between the Batopilas Mining Co. and the Batopilas Mining, Smelting & Refining Co., Ltd. of London. The latter company has a capital stock of £300,000, divided into 3000 shares of a par value of £1. Of the stock of the English company 250,000 shares is to be placed in the American company's treasury permanently, 50,000 shares is to be sold at \$7.50 per share, and the balance of 25,000 is to be held in reserve in the treasury of the English company. The mines, mills, and haciendas are to be turned over to the English corporation under a lease running 25 years. The mines include at present the Todos Santos, Cinco de Mayo, the Ballinas, and the San Miguel, on all of which a vigorous campaign of development and extraction is planned. The contract provides that the English company shall pay, both principal and interest, the entire bonded indebtedness of the Batopilas Mining Co. The option on the Campo Morado in the State of Guerrero, Mexico, has been allowed to lapse. The option, as it stood, ran to John B. Farish and the price named for the property was \$10,000,000. Another option has been given to the Exploration Co., Ltd., of London, and Philip Foster is now busy examining the mine. In order to secure the option the Exploration company was required to pay over by way of advance or loan, to José M. Ortiz the sum of £25,000 to be used in erecting a concentrating mill. It is stated that this sum has already been paid to the Mexican owners of the property. It is claimed that the Campo Morado is the greatest mine in Mexico today in point of developed tonnage. The real problem to be solved is transportation. The mine lies in the heart of the Sierras; it must have a railroad to do it any kind of justice. While a road can be constructed up the valley of the Balsas river, the work will be both arduous and costly. The Pinguico Mines Co. reports for the five months ending September 1 as follows: Ore milled, 32,664 tons; product-bullion, \$331,485; concentrate, \$117,268; total gross value, \$440,453; net profit, after deducting all expenses, \$195,073. Average monthly net profit for five months, \$39,014. Monthly dividend requirements, \$10,000. The floating debt, which on April 30, 1909, amounted to \$127,100, has been paid.

MEXICO.

Zinc Smelter for Mexico. — Patent Law. — Necaxa Dam. — Panama Canal.—Pump-Sluicing Plant.

The zinc problem in northern Mexico, caused by the United States tariff on zinc ores, seems likely to be solved by establishing a zinc smelter at Sabinas, Coahuila, 72 miles south of Eagle Pass. It is expected that by January active work will be begun on the erection of a plant. The scheme is being backed by J. T. Willet, with the support of Kansas City capital. There are coal mines in the neighborhood, a water-supply can be obtained, and it is favorably situated with regard to transportation. The smelter can be shipped to Europe in bond on through bills of lading by way of New Orleans and Galveston. Mr. Willet states that he has secured a large tract of land near the International railroad lines, and a private track will be laid to connect with the railroad. The State Government has granted a liberal concession, and it, therefore, seems certain that the new enterprise will soon be in working order.

The regular meeting of the Instituto Mexicano de Minas y Metalurgia took place September 30. A semi-official paper was read by Leopoldo Salazar on cyanide patents in Mexico. The object of this paper was to foment a discussion among engineers and other interested parties, on the basic principles of the patent law. We learn from high authority that

there is a serious movement on foot in Government circles to reform the existing patent laws, and the authorities are desirous of a free discussion of the subject.

It must certainly be disappointing to a large mining company, to fail to receive the supply of electric power they had counted on, and a penalty for non-delivery of power by a specified date is especially just when a large milling plant has been installed in anticipation. We refer to the contract between the Amparo Mining Co., of Jalisco, and the Chapala Hydro-Electric & Irrigation Co., for the delivery of 700 hp. by July 1 of this year. Failure to make delivery called for a penalty of \$100 per day which is not excessive considering that the mining company is now spending approximately \$100,000 per year for 350 hp. With electricity on a basis of \$100 per electric horse-power per year the cost will be only \$70,000 yearly for the 700-hp. plant that has been installed. The power is now promised for the beginning of the year, and the accumulated penalty will go to the credit of next year's power-bill. The Amparo company is now crushing about 5000 tons per month with a 50-stamp mill, and it is the intention of the management to add 10 stamps next year. The funds for the fourth quarterly dividend, payable on November 10, are now in Philadelphia awaiting distribution.

Colonel Goethals, chief engineer of the Panama canal, visited Mexico City, principally to inspect the work of the Mexican Light & Power Co., at Necaxa, where the construction of a great hydraulic-fill dam with a concrete core, has been in progress. The failure of part of the earth-fill, in the form of a slide last winter attracted the attention of the engineers at Panama, in view of the fact that the great Gatun dam is being constructed much on the same lines. It was the desire of Colonel Goethals to make a personal inspection of the work at Necaxa, and find out, if possible, the cause of the break. He made a tour of inspection in company with E. D. Trowbridge, the general manager for the Mexican Light & Power Co., and was shown over the works by Mr. Caldwell, assistant chief engineer. Colonel Goethals was greatly surprised at the extent of the undertaking. He expressed the opinion that the failure was due to the nature of the material used, and to lack of knowledge of those actually in charge of the work of the exact performance of this material while being packed in a large hydraulic fill. He further stated that the manner in which the work was now being done, made it absolutely certain of success, and that the Necaxa dam would, in some respects, be superior to the Gatun, as the former would have a concrete core which would be impossible in the case of the latter. The Necaxa dam, when completed, will have a head of 150 ft., while the Gatun dam will have only 85 ft.; the length of the Gatun dam will be greater, and the base will also be wider as Congress and the engineers insisted on building the dam so thick that even a layman could see and believe in its security. The Gatun dam is being built of river deposit, that is, gravel, with a large percentage of sand. In discussing Panama affairs with Colonel Goethals he remarked that the contract for the machinery for the large hydraulic-pump sluicing plant for the Corazal division had been let to the Worthington Pump Co., of New York. This plant will be of particular interest to placer miners throughout the world, as it will be the biggest example in the way of handling dirt by hydraulic methods yet attempted, and the data obtained from the excellent records that are always kept in the canal work, will be of value in the design of similar enterprises in future. A prism of the canal immediately south of the Miraflores lock-site is to be excavated by means of hydraulic giants, and the dirt, as washed, sluiced into sumps, from which point it is to be elevated by dredge-type centrifugal pumps, and distributed over the swamp-lands on either side, filling and reclaiming them. The volume of dirt to be handled is approximately 8,000,000 cu. yd., and the plant will consist of 5 units, each capable of handling 300 cu. yd. per hour. As there is no natural head of water obtainable, pressure-water, under a head of 130 lb. per sq. in., will be developed by pumping salt-water. The total capacity of the pumps will be 30,000 gal. per min. Besides the pressure-pumps, dredge-pumps, and giants, there will be required about 10,000 ft. of main and branch-pipes. The

total capacity of the plant will be between 30 000 and 40,000 cu. yd. per day of 24 hr. The power for driving the pumps will be obtained partly from the existing electric power-distribution system, and partly from a special steam-plant which is included in the contract. The plant will be installed and running inside of six months.

LONDON.

Oroville Dredging. — New Equipment. — Reaching into Colombia. —
Globe & Phoenix, Rhodesia.

The first meeting of shareholders of the new English company formed to take over Oroville Dredging was held this week. It will be remembered that the American company of that name was formed in 1905 to take over and consolidate the properties of the Boston & California, the Oroville Mining, the Oroville Gold Dredging & Exploration, and the Bear River companies. The shares proved so popular in England that the majority are now held here, but on the other hand it must be confessed that recently the secretiveness of the American directorate and management caused the shares to lose caste. In order to bring the direction of affairs more into the hands of the majority of shareholders it was decided to transfer the property to an English company. This was accordingly done in June last, and the London Venture Corporation is now supervising the direction of affairs. It is interesting to mention also that the Consolidated Gold Fields of South Africa own a substantial block of shares, and have a representative on the board. As an example of the irritating methods of the late American board, I may mention that the report for the operations during the year ended July 31, 1908, has only just been published. This habitual delay has led to all sorts of unfounded surmises detrimental to the management and the property. It is a pity that the advantages of having an excellent property and a first-class manager should be neutralized by a policy of secrecy and delay which is usually the characteristic of unsound companies. It is announced that the directors are considering the advisability of scrapping the present plant and substituting new dredges having a bucket-capacity of 13 cu. ft., similar to those working at the Yuba Consolidated. It is only 18 months since some of the nine dredges now at work were remodeled with 7-ft. buckets, but the great saving in costs promised by the larger size would pay for the new plant in less than two years. It is estimated that the life of the various properties is 14 years, so that the saving effected by improved plant will make a vast difference to the eventual profits. The English company has recently concluded arrangements for the acquisition of 22,000 acres of gold-bearing gravels on the Nichi river, six miles above Zaragoza, in Colombia. So far 310 acres have been thoroughly prospected by drilling, and 13,000,000 cu. yd., averaging 31c., have been proved. The property is held by a West Virginia corporation, the Pato Mines Co., of the stock of which the Oroville Dredging Co. acquires 75% in return for the provision of working capital. To provide this money, Oroville Dredging is creating £62,500 debentures.

During the last few months rumors have been afloat regarding a new discovery at the Globe and Phoenix mines in Rhodesia. These mines, or at least the Phoenix, have been prosperous in the past, but recently a dike threatened to cut out the ore. During July and August, the shares began to go up, clearly showing that somebody knew of a turn for the better, but to all kinds of appeal the directors returned no answer and vouchsafed no information. Then, on September 3, a small paragraph was issued in the press announcing the driving of 140 ft. through high-value ground. As a matter of fact this explanation was far from telling the whole story, as may be judged by the half-yearly report of the directors, and the interim report of H. A. Piper, the consulting engineer, which have been issued this week. The Globe & Phoenix company was formed in 1895 to acquire the Globe and Phoenix mines, 140 miles north of Bulawayo, Rhodesia. Milling commenced in 1900 with 40 stamps; a cyanide plant started work in 1901, and a slime-plant in 1907. The Globe mine is closed, and for several years the Phoenix has been the mainstay of the company. From the

commencement up to the end of 1908 dividends, amounting in all of £1 14s. 6d. per £1 share, on a capital of £200,000, have been paid, which means a return of 172½% on the nominal capital of the company, but it must not be forgotten that in 1895, 50,000 of the shares were issued at £2, and in 1899, and again in 1902, new issues were made at £4 each, facts which make a considerable difference when estimating the return on investors' money. The report of the directors now issued is dated September 15, and that of Mr. Piper, September 9. The important information contained in these reports is the announcement of the finding of the vein in place below the intrusive dike. Furthermore, the veins have widened, and the newly developed parts are of much higher metal-content. At various parts substantial bodies of ore, averaging 44 and 52 dwt., have been developed, and the estimated reserves on June 30 are given as 168,984 tons, containing 22 dwt., an average which is 6 dwt. higher than the reserves contained six months ago. During the first six months of the year the 40-stamp mill crushed 35,051 tons and extracted 24,986 fine ounces, or 13.22 dwt. per ton. The mill-feed assayed 20.63 dwt., and the tailing 6.04 dwt. The cyanide plant treated 20,364 tons of sand, having an assay value of 5.91 dwt. The extraction was 1928 oz., or 2.15 dwt., leaving 3.76 dwt. in the residue. The slime-plant treated 11,783 tons of accumulated slime, assaying 2.5 dwt., leaving 0.45 dwt. in the residue; and 2780 tons of current slime, assaying 5.82 dwt., and leaving 3.82 dwt. in the residue.

BUTTE, MONTANA.

Butte-Milwaukee.—Zinc-Concentrator.—Butte-Ballaklava.—Smoke Suit.—Ohio-Keating.

There is good prospect for an early resumption of work by the Butte-Milwaukee Mining Co. on the Colonel Sellers group of claims in the North Butte portion of the district. Contracts are being made in New York for work to be started within a few weeks. The big strike in the Tuolumne mine and the boom in Butte & Superior have attracted attention. The Colonel Sellers claims adjoin those of the Butte & Superior. A three-compartment shaft has been sunk more than 700 ft., and it is proposed to carry the shaft to a depth of 1500 ft. before the veins are opened by cross-cut. The Butte & New York company is a holding corporation for the Butte-Milwaukee. The announcement is made that the American Metal Co. will build a zinc concentrator for the Butte & Superior and also take a large financial interest in the company. There remain \$280,000 of an authorized issue of \$500,000 of bonds yet in the treasury. The Butte & Superior owns half a dozen old producing silver mines in the North Butte section of the district, and the Blackrock group has been developed for copper deposits, but in doing so an immense tonnage of high-grade zinc ore has been blocked on the levels above the 1200-ft. W. A. Clark, who has a big zinc mine in the Elm Orlu, was the first to ship ore for its zinc, but the Butte & Superior and American Metal Co. will go into the industry on a large scale. The concentrator will have a preliminary capacity of 500 tons per diem, and will be erected at a cost of \$150,000. The Blackrock mine can furnish that quantity of zinc ore without much effort. It is said that a zinc smelter will eventually be built in Butte. Especially rich in high-grade zinc ore are the mines of the Butte & Superior, Lexington, Alice, and Moulton companies. The old Emma mine, owned by the Butte Copper & Zinc Co., also has an immense tonnage in sight. The Butte-Ballaklava company is pushing development on five levels in its mine, and has just cut into the second large orebody on the 1400-ft. level. On the 1200 the orebody has widened to 7 ft., all first-class ore, much of it glance and bornite. The company has placed a contract for a new steel head-frame, 98 ft. high, to be in place in about 90 days.

The farmers of the Deer Lodge valley have not yet abandoned their fight on the Amalgamated smelter at Anaconda, and have given notice of appeal to the United States Circuit Court of Appeals, accompanied by a long assignment of errors. The farmers assign as one error the refusal of Judge Hunt to order an arbitration after the farmers had

expressed a desire to arbitrate. Another charge made in the assignment is that the agents of the Amalgamated made threats to keep up the fight in the courts until the farmers didn't have money enough left to buy breakfast.

The Ohio-Keating Gold Mining Co. has just installed one of the most complete gasoline plants in the West, and the property is in such good shape that regular and permanent shipments of ore can be counted on by the first of November. One shipment was made a few days ago. The veins are showing up better every day. The drift on the 120-ft. level is all in ore, averaging 2 ft. wide, and giving an average of \$50 per ton. Shaft sinking has also been resumed.

KALGOORLIE, WESTERN AUSTRALIA.

Output.—Chaffers Resumes.—Associated Northern Unwatered.—Lancefield.—Labor Agreements.—Water Rates.

The gold output in this State for July was valued at \$2,825,000, while dividends totaled \$470,000. So far this year we are \$580,000 in gold and \$560,000 in dividends behind last year. The yield may be expected to still further decrease despite the Chaffers, a new producer, which lately crushed 4120 tons yielding \$39,000 gross and a profit of \$5500. This mine is on the south end of the Golden Mile, along with the Main Reef, the Hannans Star, and Deep Levels; the two latter having been consolidated. The new work in the Chaffers is due to tributors finding a new lode. Now the company is working this and crushing both oxidized and sulphide ores at the Main Reef mill. The oxidized ore is a soft lode material and is crushed wet in a Humboldt ball-mill at the rate of some 85 tons per day. The sulphide ore is crushed dry in two No. 5 Krupp mills, roasted in three Edwards furnaces, mixed with weak KCN and the pulp from the wet mill, ground in four 5-ft. pans, agitated in ordinary tanks, and filter-pressed. This treatment gives satisfactory results. It will not be many months before the Golden Link Co., at the north end of the 'Mile', will start erecting a plant, presumably for dry-crushing and roasting. About 80,000 tons of \$10 ore is now opened up.

The Kalgoorlie Amalgamated Leases are being vigorously prospected after years of idleness, save some work by tributors; and some really promising ore is being found. It may be mentioned that telluride was first discovered at Kalgoorlie in this mine. The North Kalgurli Co. has just duplicated its 10-stamp mill and cyanide plant, but it may be difficult to keep 20 stamps at work. The Associated Northern has unwatered its mine from levels 7 to 12, and is about to do some prospecting at 1050 ft. The general opinion about the famous Brownhill-Iron Duke-Oroya shoot is that there is nothing under it or east of it. The Associated company announces its ore reserves as 483,517 tons worth \$9.50 per ton. The average ore in this mine runs some 6% sulphur, and roasting is much slower than at other mines. In development the Perseverance is spending over \$20,000 monthly, and has opened up a deal of average grade ore. In the Ivanhoe, the East cross-cut, in section 7 at 1970 ft., is in 47 ft. of ore worth \$11.50 per ton.

Three feet of mineralized schist worth \$2 was found, by diamond-drilling from the 2500-ft. station, in the Edwards shaft of the Great Boulder, 48 ft. west from shaft. At 98 ft. west, 14 ft. of quartz worth \$10.50 was also found. After years of experimenting, many breakdowns, and changes of management, it would appear as if the Lancefield mine, some 210 miles northeast of Kalgoorlie, was about to make profits. The ore is difficult to treat, but the trouble is gradually being overcome. Extraction is now about 81%. The wages agreement between the Chamber of Mines and the Labor Unions terminates next month, and several weeks ago a conference was held between the interested parties. The Union wanted a few concessions, but the Chamber did not agree, although quite agreeable to renewing the existing arrangements for another three years. The Unions required a few weeks' time for consideration, and next week will take a ballot on the question.

From time to time the Water Scheme has been mentioned in these notes. The Scheme pays all working expenses and interest on main and supplementary capitals, and something for renewal of pipes. The sinking fund of \$450,000 per an-

num is not met from revenue from water but is a direct charge on the whole State. The Government has been allowing the Mines Water Trust—the mines on the Golden Mile—water at \$1.25 per 1000 gallons for general purposes, but reckons that it costs \$2.16 per 1000 to deliver to it, that is, including every charge, so now they propose charging \$1.75 per 1000 to the Trust to try and get in something for the sinking fund. This, it is estimated, will cost the mines some \$200,000 extra per annum or about 10c. per ton. The matter is still under discussion. The corrosion of the main pipes continues, and much experimenting is being carried on to discover means of protecting them.

The July returns from the principal mines were as follows:

| Name. | Tonnage. | Yield. | Profit. |
|--------------------------------|----------|-----------|-----------|
| Associated | 11,645 | \$105,000 | \$ 30,000 |
| Associated Northern Blocks.... | 3,760 | 30,000 | 10,000 |
| Golden Horseshoe | 25,107 | 255,000 | 100,000 |
| Golden Ridge | 2,280 | 28,000 | 14,000 |
| Great Boulder Proprietary | 18,327 | 250,000 | 130,000 |
| Great Boulder Perseverance ... | 19,466 | 145,000 | 22,000 |
| Great Fingall | 10,755 | 73,000 | 6,000 |
| Hainault | 5,807 | 38,000 | 6,000 |
| Ivanhoe | 19,427 | 205,000 | 100,000 |
| Kalgurli | 10,710 | 140,000 | 80,000 |
| Kalgurli South | 9,038 | 62,000 | 13,000 |
| Lake View Consols..... | 11,011 | 65,000 | 13,000 |
| Lancefield | 6,777 | 54,000 | 4,500 |
| Oroya-Brownhill | 11,880 | 100,000 | 33,000 |
| Oroya-Black Range | 4,493 | 56,000 | 20,000 |
| Sons of Gwalla | 13,379 | 110,000 | 39,000 |
| Sons of Gwalla South | 2,013 | 21,000 | 5,500 |

DENVER, COLORADO.

Dredging at Breckenridge.—Development at Leadville. — The Doyle-Burns Case.—Cripple Creek News.—Coal Production.—Ouray Items.—Legal Decisions.

Mining throughout the State is active and prosperous. The weather has not, as yet, interfered with work. The Breckenridge dredging industry has been especially favored in this respect, and the operators hope to continue without interruption until December 1. The four dredges in the district are averaging \$100,000 total product per month. The value of the Swan river gravel, ranges from 20 to 25c. per cu. yd., and that in French gulch from 30 to 50. The gold production of Summit county for 1909 is estimated at about \$900,000, of which only about \$100,000 will come from the lode mines. Leadville mines have been unusually active throughout the season. Much prospecting and development has been done north and east of the city. The East Lake Mining & Milling Co., operating in the Holy Cross district, has uncovered a large vein of fair grade gold ore in the breast of its 2200-ft. adit, and is developing from the adit level. The old plant of the Harrison Reduction Co. has been purchased by the Cloud City Milling Co.

The famous Doyle-Burns law suit which has occupied the courts of Colorado and Iowa for the last 17 years, has been settled out of court. The only item of the settlement made public is that each party has to bear half the costs. It will be remembered that Doyle and Burns were partners in the famous Portland mine, of Cripple Creek, and the case was brought by Doyle against Burns to get half of the stock and dividends of Burns in the Portland company. Mining men all over the West who have been watching the progress of the Cripple Creek Deep Drainage tunnel, will be glad to learn that its completion is now assured. The \$160,000 lacking for the work has been secured. During September the tunnel was advanced 355 ft., making the total distance from the portal 11,022 ft. The breast is now under Regua gulch, between Beacon hill and Grouse mountain. The production for September from the district was \$1,297,440. This brings the total production for the nine months of 1909 up to \$11,911,245. Construction work on the new Portland mill is progressing rapidly, and an addition to the Independence has just been started.

Few people realize the extent of the coal industry in

Colorado. Coal is mined in 15 counties, of which Las Animas is the heaviest producer. The report for the first six months of 1909 shows a production of 4,823,412 tons, which is an increase over the same period in 1908 of 406,936. The coal production is a good index of the condition of the other industries in the State, and with winter at hand and business increasing, operators are predicting a ten million ton production for the year.

Ouray has the proud distinction of having the most productive gold mine in the world. The quarterly report of the Camp Bird, Ltd., gives the net profit derived from the mine during the months of May, June, and July, as \$761,806. At the present rate of operation the profits for 1909 should exceed the three million mark. The Mono-Baltic Mining & Smelting Co. has let the contract for the concrete work on its new smelter at Ironton. Supplies and machinery for the smelter are being delivered.

Now that the question of taxing idle mining properties has been brought to the public attention, the recent decision of Judge Sheafor, regarding the case brought by some of the idle mining properties in the Cripple Creek district against the officials of Teller county, has more than passing interest. The case was brought by the plaintiffs to secure relief from exorbitant taxation. They argued that they should not be taxed a higher rate than the lowest rate per acre on producing properties. The decision favored the plaintiffs, and now Teller county will have to return over \$10,000 to the various companies which paid their 1908 taxes under protest. The other decision of interest to mining men is that of District Judge Allen. The case was brought by Jacob and Henrietta Schloss, of Leadville, to force the Western Mining Co. to put down a shaft on the Neusitz placer according to its contract. The company had already drilled an 800-ft. hole on the property without discovering mineral, and Judge Allen ruled that a lessee of a mining claim is relieved of fulfilling the terms of the lease when to do so would be unremunerative.

TORONTO, CANADA.

Cobalt Dividends and Development.—Coal Strike.—Sault Ste Marie Iron Furnaces.—Yukon Gold Production.

The payment of large and in some cases increased dividends by the leading Cobalt companies for the third quarter of the year has had a marked influence on the market,

Cobalt, Ontario.

sending up the prices of most of the dividend-paying issues, while other stocks continue at a low level. In all seven companies have declared dividends for the current quarter calling for total payments amounting to \$1,328,531. Nipissing pays 5% dividend and 2½% bonus; Crown Reserve, 6% dividend and 5% bonus; Kerr Lake, 6%; Buffalo, 8%; Right of Way, 6%; and the Temiskaming & Hudson Bay, with its diminutive capital, the customary 300%. La Rose disappointed expectations by failing to increase its returns beyond the 3% dividend plus 1% bonus which it has been yielding for some time, and its stock is sagging accordingly. The total amount paid in dividends and bonuses by these seven companies since their organization is \$10,242,247. The Cobalt Central passed its dividend in order to enlarge its concentrator at a cost of \$30,000. There are now some 71 companies in actual operation at Cobalt with between 3500 and 4000 men on the payrolls. A factor

which will very shortly add to the productiveness of the camp is the development of electric power by several companies operating on the Montreal river, which possibly before the end of the season and certainly next year will be able to supply power for mining operations. Of these enterprises the most important is the Cobalt Hydraulic Power Co., at Ragged Chutes, where for six months 400 men have been engaged in driving underground workings.

The most important discovery made recently is the finding of rich ore on the Red Jacket property, which lies about two miles south of the town of Cobalt, indicating an important extension of the silver-producing area. This property belongs to a company capitalized at \$1,250,000, of which Burr E. Cartwright is president, is equipped with a good plant including a 100-hp. boiler and 6-drill compressor, and has spent about \$35,000 in equipment and development work. The main shaft was sunk on a vein of calcite showing smaltite in places, but no encouraging results were obtained, until about two weeks ago when, at the 125-ft. level, rich ore was shot through with native silver was taken out. The width of the vein at this depth is 35 in. A great deal of trenching has been done in the neighborhood, but this is the first native silver so far obtained. The Crown Reserve has secured a controlling interest in the Silver Leaf, the property of which adjoins its holdings, and is strongly represented on the newly elected directorate of the Leaf. John Carson is president of both companies. A good find, consisting of a vein 8 to 12 in. wide, has been made on the 75-ft. level. The 10-stamp mill of the Colonial mine is now completed and operation will be resumed as soon as air can be obtained from the power companies. Surface work on the Nipissing has resulted in the discovery of additional veins. There are now 131 valuable veins, the latest carrying an inch or two of plate silver. Gangs are at work stripping veins 129, 130, and 131, which show surface decomposition. They have taken 40 bags of ore from the muck, which will run 5000 oz. silver per ton. The fresh discoveries are in the Keewatin formation. A general belief obtains in mining circles that the Crown Reserve company has in contemplation a scheme for the drainage of Kerr Lake. The company has a rich ore reserve, but if much stoping were undertaken it would incur the risk of flooding from above. Sooner or later the drainage of the lake will be necessary if the immense resources below its bed are to be realized. The equipment of the Silver Cross mine has been greatly improved during the last few weeks and No. 2 shaft is now being put down to the 200-ft. level. It is being sunk on a calcite-smaltite vein, the silver content of which is increasing with depth. At the Temiskaming & Hudson Bay a winze is being sunk for 50 ft. from the 200-ft. level at the intersection of two good veins from which driving will be undertaken. A new main shaft will be put down at this point later on. The Prospectors Exploration & Development Co. has staked 10 claims in a new district on the lower branch of the Meteor river about 16 miles southeast of Gowganda. There has been a rush to this neighborhood lately and hundreds of claims have been recorded. The shipments from Cobalt last week amounted to 516 tons, the Cobalt Lake, Nancy Helen, and Silver Cliff, all which have been infrequent shippers, re-appearing on the list.

News of the Dominion Coal Co. strike at Glace Bay, Nova Scotia, is very contradictory, the only thing that appears certain in spite of frequent assertions to the contrary, being that the strike is still on and considerably limiting the output of the collieries. The Dominion Iron & Steel Co. is yet drawing a large proportion of its fuel supply from the United States. The announcement that the troops are to remain all winter does not augur well for a speedy settlement. Eugene Haanel, of the Department of Mines, recently announced that the Lake Superior Corporation of Sault Ste. Marie were making arrangements to adopt the electric smelting process for the treatment of iron ore, and preparing to install several electric furnaces of the type in successful operation in Sweden. The annual report of the directors of the Corporation just issued in advance of the annual meeting to be held next week makes no mention of any such intended departure—a rather singular omission unless Mr. Haanel's announcement was premature. The re-

port states that an additional blast-furnace with a rated capacity of 400 tons per day, will be constructed which will obviate the necessity of their buying pig-iron, and that the new merchant steel mill will enable them to manufacture structural steel in addition to rails, and insure the steady operation of the steel plant. The by-product coke oven provided for will supply the latter with all the coke needed. The financial statement shows a surplus of \$1,093,372 for the financial year, of which \$501,424 was contributed by subsidiary companies. The profit and loss balance is placed at \$522,178. The output of pig-iron was 130,268 tons, of bessemer rails 126,733 tons, and open-hearth rails 31,732 tons. While the pig-iron output was somewhat less than that of the previous year, the production of rails showed an increase.

The annual report of Alexander Henderson, Commissioner of the Yukon, gives the total gold production of the territory for the fiscal year, which ended March 31, as 217,350 oz. of the value of \$3,260,263, being an increase of \$440,000 over the preceding year. The Government received royalties on gold amounting to \$81,507. Mr. Henderson speaks in a highly optimistic strain as to the future of the territory, predicting great things from the operations of the Yukon Gold Co. when their system is completed. They will operate seven dredges and three hydraulic elevators. Experiments with quartz lead to the belief that the time is not far distant when numerous quartz prospects will materially contribute to the wealth of the territory.

LOS ANGELES.

New Record Gusher at Coalinga. — Development to South

The record well for Coalinga, judged from the spectacular standpoint as well as from the standpoint of actual production, is the Silver Tip No. 1, on section 6, T. 21 S. R. 15 E., which recently flowed 22° gravity oil at a rate conservatively estimated at from 12,000 to 20,000 bbl. per day. This well is in the same section and but a short distance away from the famous Lucile, and is situated but a little more than a mile west of the town of Coalinga. The phenomenal flow began at 4 a. m., September 22, and continued to 9 a. m. September 23. It has been producing almost continuously ever since, and is at present yielding about 3000 bbl. per day with great quantities of gas. Nearly all of the oil has been saved, owing to the prompt work of those in charge. The well gushed for a few hours over a month ago, at which time large quantities of sand were thrown out with the oil. The present flow is, however, accompanied by relatively small quantities of sand as compared with the first flow or with other gushers, such as the Guthrey No. 1, which has made history for other parts of this same field, and it is quite unlikely that the sanding troubles encountered in so many wells will interfere with the Silver Tip. Several other wells in section 6, such as the Blue Moon, Jefferson No. 1, and De Lux, are giving promise of making big productions as soon as they are completed.

The wells of the American Petroleum Co., which have been such excellent producers, have steadied down to a yield estimated at about 5000 bbl. per day. When these wells were first brought in they produced over 7000 bbl. per day. Such decrease in production is always to be expected. The Nevada Petroleum wells, just east of those of the American Petroleum Co., are now being cemented above the 'Zone D' or deep oil sand, the same from which the Lucile, M. K. & T., and other deep Westside wells obtain their oil. The deep sand is present in all these wells but as yet has not been tested. Development is going forward rapidly in the Westside territory, among the most active operators being the K. T. & O. (Southern Pacific), which is endeavoring to protect its immense and until very recently large undeveloped properties. Water is causing much trouble in the Eastside field, especially in the east half of section 22, T. 19 S. R. 15 E. It is the belief of those well versed in the underground geology of this territory that much of the water is 'stray water', that is, water that has gotten into the formations associated with the oil sands during the drilling of the wells up the dip of the strata from those in which the water is now being encountered.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Discovery of the Great Comstock Mine.

The Editor:

Sir—Reading in the MINING AND SCIENTIFIC PRESS of July 3 of the fiftieth anniversary of the discovery of the Comstock mine recalled my experience with the event. Being one of the first to arrive on the scene, I note some discrepancies in the dates given, the discovery having been made earlier in the year. In 1859 I was living on Montezuma hill, Nevada county, about seven miles north of Nevada City. When the reports were circulated in March that rich mines had been discovered at Washoe, all that was known locally was that a valley by that name lay just east of the State line opposite Nevada county. There being no telegraph nor even any mail service, the reports were meagre and little could be learned concerning the new strike. John Terry, a mine-owner on Montezuma hill, suggested that we go over the mountain as soon as the trails were free of snow, which would be about May 1, or perhaps a little earlier. When the time came for the start the news of the wonderful find had spread all over the country, and the trails were alive with stampeders, both on foot and horseback.

Mr. Terry, myself, and two other miners were among the first to 'hit the trail'. We soon fell in with R. H. Warfield and O. H. Pierson from Marysville, who joined our party. We were several days in reaching the Truckee river, at a point about halfway between the present towns of Reno and Truckee. On reaching the Washoe valley we were told that the new mines were over on the eastern slope of the high mountain to the east of Washoe valley, some 15 miles. The trail over the mountain was rough and there was much speculation in our party as to what kind of a mine could exist in such a mountain. After passing up through a steep rocky canyon, we reached the summit of the divide, and passing over to the north side of Mount Davidson, found the dim trail that led us around to the eastern slope of the mountain, where we found four or five men at work in a pit which was about 10 ft. deep, about large enough for two men to work in, say 10 ft. long by 6 or 8 ft. wide, and about 8 ft. deep. On the lower side of the pit they had two rockers and a stream of water, which they had brought down from a spring above and around on the northeast side of the mountain; this stream was very small and was conveyed in a ditch about like a small plow furrow, the water barely reached the pit. It gave enough to run the two rockers by sinking two small holes about 2 ft. deep for the water to accumulate in. Pat McLaughlin, Peter O'Riley, and two other men were there at work in the pit. Mr. Comstock was down in the canyon cutting poles to build a frame for a canvas house. At that time, early in May, they were camped under a juniper tree about 100 yards above the pit on the side of the mountain. We all rode up

to the pit and sat on our animals watching the work which was a new kind of mining to us. The dirt being washed in the rockers was a decomposed gossan. The hard lumps were being piled at one side. None of us had ever seen such a mine. We expected to see gravel with free gold in it, as in California. One of our boys had the hardihood to ask where the new mine was, not taking any stock in that stuff. They were getting quite a lot of mineral, which to us, looked like lead. It seemed to have some kind of metal in it but no one seemed to know what it was worth per ounce. Some said it was worth \$10 per oz. and others said \$4. No assays had been made and but little sold, so no one really knew. Late in the afternoon, our party started for Carson river. We had not got out of sight of all there was of Virginia City at that time, when we met a man with an axe on his shoulder. His clothing was in rags and he was about as tough looking an individual as I ever ran across. The man proved to be H. T. P. Comstock, and was very talkative. We all stopped in the trail to hear what he had to say. He squatted down on his axe-handle and made us a proposition to the effect that if we furnished the grub and tools, to run an adit some 100 ft. or so to tap the lode 50 ft. below the surface at the pit, he would give us 50 ft. on the ledge—locations were reckoned by the foot at that time. Our party was so impatient to get away from the place that they would hardly hear him through, and we all rode away disgusted with the whole country.

R. H. CAMPBELL.

Seattle, September 24.

Wilfley Tables as Classifiers.

The Editor:

Sir—The use of Wilfley tables as separators of slime from sand, referred to by P. R. Whitman in the discussion on 'All Sliming', in your issue of September 18, is a matter of great interest, and the wonder is that this method was not generally adopted years ago. In your note appended to Mr. Whitman's communication you state that the system was in use at the Exposed Treasure mill 'as early as 1902'. It was first in use there in 1901, and early in 1902. W. K. Reese, who was then in charge of the cyanide plant, found that by so placing a short piece of board that it could be moved backward or forward under the discharge-lip of the table, quite a clean separation could be made, all the slime being discharged into one launder and clean sand into the other. By means of this slide any variation in the amount of slime in the pulp could be taken care of, and by proper adjustment of the table and of the wash-water, a practically perfect separation of slime from sand was made.

The Exposed Treasure pulp contained a large amount of 'real slime', that is, clay, and previous to the use of Reese's slide on the Wilfley, it was frequently impossible to get a leachable product in the sand-percolating vats. After its introduction the sand vats gave no trouble. One objection to this use of Wilfley tables might be the small capacity compared to cones or to Dorr classifiers, but, as it does not interfere in any way with the simultaneous use

of the table for concentrating, it would be specially suitable in mills treating gold and silver ores by concentration and cyanidation. It is also to be noted that by excluding cones or other classifiers, a saving in the cost of installation and a simplification of the plant is made, the saving in vertical height alone being in some instances of much importance.

BERTRAM HUNT.

San Francisco, September 21.

The Editor:

Sir—In a recent number of the MINING AND SCIENTIFIC PRESS inquiry was made as to the first use of the Wilfley table as a classifier. In 1897, at the Revenue mill, at Ouray, Colorado, the sand-free slime was sent from the head of the tables to canvas-tables 50 ft. long on which the gray-copper slime was saved. W. A. Garrett was superintendent of the mill.

H. W. REED.

Salt Lake City, September 24.

A Vein and Its Apex.

The Editor:

Sir—The importance of common understanding in the usage of terms warrants discussion particularly of those which are necessarily important in litigation. I submit the following as representing usage. Exactness in a scientific sense is necessarily often modified in practice by the legal situation. That is, one term is interpreted in the light of previous court determinations.

A vein (or lode) is an (1) elongated or tabular body of mineral matter, (2) in place (3) which extends with notable continuity through the mass of the country rock (4) definitely and visibly bounded on either side, or, lacking this, distinguishable from the country by the composition of its materials, and (5) as a mineral deposit, derived from sources external to the adjacent rocks. These characteristics of form, composition, and genesis, though often inaccurately conceived in detail, are nevertheless all involved in the prevailing idea of a vein among miners in the United States.

The apex. Fundamentally, the apex is the outcrop of the vein, if outcrop exists. Many veins, however, are not exposed at the surface. The top of the vein may be covered by soil, by a deep mantle of glacial debris, or by loose rock accumulated by landslides or snow-slides, or by volcanic ejectamenta of later age than the vein. More rarely a vein may terminate upward, for other geological reasons, against some particular rock formation or against a fault which has produced such great displacement as to totally isolate a part of the vein making it legally a separate vein. The miner also differentiates between dislodged vein matter and vein 'in place'. Fragments of vein matter separated from their original position at the top of the vein and scattered down a hill-slope by erosive agencies are called 'float'.

Vein matter. Vein matter may be defined as any mineral or aggregate of minerals which the miner has found by experience constitutes or is associated with commercial ore in a lode. In exceptional cases,

precisely the same minerals may be found disseminated through the country rocks or as erratic aggregates, and even, in certain rare instances, sufficient in quantity to render great masses of rock commercial ore capable of profitable extraction if worked on a large scale by the application of expedients of economy, like the porphyry bodies of Kelvin and Bingham. Such bodies lack the essential characteristics of form and structure, and generally of genesis, as comprehended in the prevailing conception of a vein or lode, and are called 'masses' or 'deposits'. They are not regarded as having apices, as the apex is understood in the procedure of locating and patenting lode mining claims. The 'apex' must, therefore, possess all the essential features of form and structure exhibited by the deeper parts of the vein, of which it is the top. It may be radically different in color, due to weathering, may be greatly enriched or it may be leached and robbed of value, but it must be vein matter. The apex, comprehensively defined, therefore, is the line drawn through the highest points at which the vein as an intact body is found in place when followed upward along its dip.

Ore. An ore is any mineral or aggregate of minerals which may be removed from the rocks of the earth and sold with profit, or which, with the application of progress in invention or change of conditions shows promise of becoming a source of profit. The term ore is most frequently applied to the metallic minerals. The metallic substances which are converted from their natural state to human uses in the arts and industries are subject to varying difficulties of recovery, on account of their geological or mineralogical associations, geographical situation, the natural facilities or the necessary capital for their exploitation, the stage of progress in the technology of their treatment and the vagaries of market. Since an ore is essentially a commercial substance, that may become an ore in the future which is not an ore today, or vice versa.

I hope that discussion may lead to increased uniformity in the use of the terms selected.

J. W. FINCH.

Denver, Colorado, September 11.

Sweden has lately felt secure as to future iron ore production, according to E. D. Winslow, Consul-General at Stockholm. The Swedish deposits in the north are very large and are now being worked by modern methods. There are reports of large finds in Ouenza, in Algiers, and already the Krupp, Gelsenkirch, and other large firms have formed a company to work them. Germany has been the main customer of Sweden's iron ore, but the news of the reduction of the American duty on the crude ore has made the Swedish iron-ore exporters look for a market in the United States, and already some 200,000 tons are on the way to Philadelphia.

Reports from Brazil speak of large discoveries of iron ore in that republic, but although the report of the Government of Brazil lately issued is sensational, no large production is expected from that quarter for a few years.

located as a mining claim adjoining the No. 1 North, and both the above homestead entries conflicted with his ground. He had done his assessment work for years, and, like the Osseo owners, had not known of these homestead entries. In September, 1905, he entered a contest against both Beyea and Strickland on the ground that they had not complied with the statutes governing homestead entries. Neither of these men could be found when, on October 27, this contest was heard. Beyea's entry was cancelled because seven years had expired and he had not 'proved up'. The other contest was reported as decided in Blackwell's favor by the local land office, but on reference to Washington for approval was decided against Blackwell on the ground that there was no proof that he had mailed notice of the contest to the last known address of Strickland, regardless of the fact that it was known that Strickland had left that part of the country and the postmaster had no forwarding address. Before this decision was rendered it had become necessary to take action as to the assessment work for 1905, and men were kept at work until that for 1906 was also completed.

In February, 1906, the Blackwell contest against the Strickland homestead was re-instated by posting a notice on the property, and mailing one to the last address, as required by law, and November 9, 1906, the local land office accepted proof, and again forwarded the decision to Washington for approval. A representative of the Osseo company visited Washington in December and was told that if Blackwell's contest was approved, Blackwell would have 30 days' prior right to file on the land covered by the entries of Strickland and Beyea, and if his filing covered Osseo ground no objection could be interposed at the land office, as the Osseo company failed to appeal from the decision of the local land office when first advised of the conflict with the homestead entries. The information was also given that Blackwell could acquire this land with scrip, or a soldier's right, without advertizing, thus giving the Osseo company no chance to intervene. January 22, 1907, the homestead entries were cancelled, and, as Blackwell did not exercise his 30 day right of priority to file on the ground, the application for the Osseo patent was again presented at the local land office. The following July this application was again denied on the ground of conflict with the S. W. $\frac{1}{4}$ of the N. W. $\frac{1}{4}$ Sec. 15. In the meantime the history of this quarter section had been investigated and it was found that the inhabitants of a small town which is situated here had appointed Judge Wilson trustee, and through him had, in 1900, purchased this land for cash. While Sec. 16 of the Act of March 3, 1891, provides that town-sites on mineral lands shall acquire no title to veins, or to any valid mining claim, the owners of the Osseo decided to except this area from the application. October 21, 1907, the amended application was accepted and publication ordered. On December 1 all papers and proofs were filed at the local land office and the money for the land paid to the Receiver. For some reason a duplicate receiver's receipt was not obtainable, but no assessment work was done for 1907 as the company was advised by its attorney that it was not necessary, the

courts having decided that "an entry made is in all respects equivalent to a patent issued, in so far as third parties are concerned."

The following April, 1908, inquiry at Washington disclosed the fact that no money had been received there, and later investigation showed the receiver of the local land office to be short in his accounts. In February, 1909, notice was received that the application was 'suspended', with the following comment:

"(1.) Some claims do not appear to have the necessary five hundred dollars worth of improvement; if benefitted by the amounts on other claims a report is necessary from the deputy mineral surveyor, certified to by the Surveyor-General. (2.) No application to purchase appears with the papers. (3.) Proof of continuous posting during the period of publication is made by a stranger to the record."

Objection No. 1 was taken care of as suggested; No. 2 had been filed, but lost at the land office, and was replaced with a duplicate; No. 3 was explained by affidavits that the owners and attorneys did not live near the property, and the 'stranger' did. Early in March, 1909, the receiver's receipt for the application fee paid December 31, 1907, came to hand, and on March 14 was received 'Register's Final Certificate of Entry', reciting that the party has "this day made payment," although the money was actually paid more than a year before. It is presumed that the papers have now gone to Washington for discussion and criticism by the officials and clerks of the General Land Office. The owners hope that the period of five years which has elapsed since proceedings for patent were instituted may not be duplicated before they receive actual title to the property.

The history of this effort to obtain a satisfactory title to mineral land furnishes another striking example of the unsatisfactory condition of those laws of the United States under which mining property is developed on the public lands. This ground, originally a productive placer, then held for years as a quartz claim, and during that time yielding several thousand dollars, was in part entered as a homestead, and so appeared on the land office records for years, without the knowledge of those who supposed they held it as mineral land by right of location and performance of annual work. To be sure the homesteaders did not attempt to 'prove up' and acquire title, but if they had attempted to do so there is no certainty that it might not have been accomplished. The adjoining land to the north is so held, several obliging neighbors having made affidavit to the fact (?) that it is not mineral land. I do not know enough of this adjoining property to state definitely that it is more valuable for its mineral, though examination shows on the ground a long open cut, and shallow shaft, with a very pretty quartz vein containing sulphides. It certainly does not look like a very valuable farm.

Title to the Osseo ground might easily have been obtained under the homestead law within the period during which the mine was closed down, and visited by the owners, or their representatives, only for the purpose of doing the annual work. When this is done at the same time for two years, during Decem-

ber and January, a property may not be visited for 22 months. The statement made by the Commissioner of the Land Office, that the property covered in part by the Osseo claims could be acquired with 'scrip,' or by 'soldier's right,' without advertizing, leaves holders of mining claims, located on land which may be valuable for agricultural purposes, absolutely without protection, unless application for patent be made. Fortunately this condition no longer exists, a rule having been adopted by Mr. Ballinger, when Commissioner, in February, 1908, requiring "in cases of applications to locate all scripts, warrants, certificates, soldier's additional homestead rights, or to make lieu selections of public lands," an affidavit that the land is not occupied adversely, accompanied with publication and posting of notice.

Another portion of this property was included in a tract actually sold for cash to Judge Wilson, acting as trustee for parties living upon it. It is evident that in such a case as this a prospector living at a distance, and possibly even residing on the ground, might have his entire property transferred to another without his knowledge.

Another point brought out by this history is the lack of value of the ordinary abstract of title to a mining claim. How valueless such an abstract may be is shown by the reply of the attorney when questioned. He said: "Our abstract was simply of the Osseo claims as located, and not of a particular subdivision of land. Hence it might have had numerous conflicts with other claims, other subdivisions, and not be noted. Similarly an abstract of title to the S. W. ¼ of the N. W. ¼ of Sec. 15 would not disclose the existence of a mining claim anywhere." Many Eastern investors, when acquiring mining property, send out an attorney to investigate the title. This attorney usually goes through the records of location, transfers, and mortgages, but how many attorneys from the East would look up the title to the section on which the ground is located? A mining man, going over the ground, can be fairly certain, judging by the presence or absence of stakes, as to whether there are conflicting locations. The testimony of an old resident of the district aids in the conclusion. But in spite of all the care of attorney, engineer, and old resident, the property may be acquired only to be confiscated by a cash certificate, or to be claimed by some locator whose stakes have rotted away. So great an uncertainty is a serious reflection on our law. Without working hardship upon those whose claims are reasonably protected under existing conditions, a slight amendment to our mining law would ameliorate this uncertainty for those who wish to take advantage of the provision I wish to suggest. Under our existing law the recording of mining locations is regulated by the laws of the State, or by vote of the miners of a district. The records are commonly kept by the county clerk, sometimes by a district recorder, but in no case are they known to the land office. The United States law should be amended so that : (1) the locator of a claim shall be permitted to file a location notice with the local land office for the district in which the claim is located, which shall contain such a descrip-

tion of the claim that its position may be identified and entered upon the proper plats and tract-books of said land office; and (2) when such a record is made no sale of public land in conflict with this claim shall be permitted without a reasonable prior notice being mailed to said locator. Such an entry should remain on the books of the land office as long as the locator makes annual affidavit that the annual work has been performed, but on failure to make such affidavit in any year the entry should be cancelled. Proper and reasonable fees to cover the cost of such entries could be charged, and would be very small in comparison with the increased safety of title to claims held simply by location and annual work, which claims, in so far as the United States, the source of title, is now concerned, are absolutely non-existent.

IRON-ORE IN CUBA.

The iron ores which have been mined in Cuba up to the present time consist largely of hematite and magnetite and are obtained near Santiago, in the Province of Oriente (Santiago). Recently large deposits of brown ore have been attracting considerable attention, especially those of the Mayari and Moa fields in Oriente Province and those of the Cubitas field in Camaguey Province. No ores of this type have been mined, however. The following table, prepared by E. C. Harder, of the United States Geological Survey, shows the shipments, in long tons, of iron ore from Cuba since the opening of the mines in 1884.

| | Tons. | | Tons. |
|------------|---------|------------|---------|
| 1884 | 25,295 | 1897 | 454,285 |
| 1885 | 80,716 | 1898 | 168,339 |
| 1886 | 112,074 | 1899 | 377,189 |
| 1887 | 94,240 | 1900 | 446,872 |
| 1888 | 206,061 | 1901 | 552,248 |
| 1889 | 260,291 | 1902 | 699,734 |
| 1890 | 363,842 | 1903 | 623,621 |
| 1891 | 264,262 | 1904 | 387,273 |
| 1892 | 341,654 | 1905 | 561,159 |
| 1893 | 351,175 | 1906 | 640,574 |
| 1894 | 156,826 | 1907 | 681,393 |
| 1895 | 382,494 | 1908 | 819,434 |
| 1896 | 412,995 | | |

By far the larger proportion of this ore came to the United States, the imports from Cuba in 1908 being 579,668 long tons. This was about three-fourths of the total imports of iron ore; in 1907 Cuba supplied a little more than half the ore imported.

In working garnet deposits the rock is broken down by ordinary quarrying methods. It is then crushed to release the garnets and the product is washed. Hand sorting and mechanical means are employed. The garnet rock worked is mostly amphibolite, and is usually schistose. There has been some difficulty in separating the garnet from the accompanying hornblende, but jigging has been found most efficient, as in the concentration of corundum. The output is used in the shoe and wood-working industries as garnet-paper. The mineral possesses no distinct cleavage, but there is a rather distinct parting parallel to the dodecahedral faces, insuring a smooth surface for adhering to the cloth or paper, at the same time leaving a sharp cutting-edge.

PAN-AMALGAMATION EXPERIMENTS.

By H. O. HOFMAN and C. R. HAYWARD.

*In smelting an ore by a well-established process, the result is shown by analyzing the products to see whether their compositions correspond to those calculated in making up the charge; by taking account of stock to show the distribution of metal in the different products made and the losses from dust and volatilization; by casting a thermal balance to find the distribution and losses of heat; and by making a cost-sheet to ascertain, as far as possible, the necessary outlay of money. In lixiviation and amalgamation, the mode of operating has to be varied to adapt a process to the individual ore. Here a number of tests become necessary. Each will consist of a series

to get them into good working-order, and of the difficulties met in making a clean-up, as it was next to impossible to recover all the amalgam from a pan with detachable shoes and dies. While the percentage of extraction is usually based upon the assay of the tailing, it is of importance in a teaching-experiment to compare it with the actual yield from the amalgam. Instruction was given mainly with small pans, only 7 in. diam., three of which were of copper, hardened by a small percentage of silicon, and the rest of cast-iron. These pans were a great advance over the original Washoe model, but improvements in the details of construction suggested themselves, which led, in 1899, to the replacement of the pan of 1895 by the present form. This has met all the requirements of a pan that is to be used for class-work in the systematic testing of ores. These

Fig. 1.

of experiments with one variable, in order to find the conditions under which the variable gives the best result; a summary of several tests will give the best method of operating. Working a number of charges with the best method will furnish the data desired for ascertaining the recovery of metal, the size of plant needed for a given capacity, and the cost of treatment.

The Washoe process, raw-amalgamation of a silver-ore in an iron pan, furnishes a satisfactory example of this class of ore-treatment. The first amalgamating-pan with settler was put in operation at the Massachusetts Institute of Technology in 1871. It was built on the Washoe pattern by Booth & Co., of San Francisco, California. In 1895 the laboratory had three of these pans, respectively 30, 18, and 12 in. diam. They were, however, little used at that date for class-work on account of the time required

requirements are that it shall give a quantitative result which corresponds to working conditions, and that it shall be small, easy to run, and easy to clean.

Details of the pan are shown in Fig. 2 and 3, and the battery of 10 pans in the laboratory is represented in Fig. 1. The pan, Fig. 2, is cast in one piece. It has a flat bottom, which forms the lower grinding-surface; its inside dimensions are: diameter at bottom, 7 in.; at top, $7\frac{1}{4}$; height, $4\frac{5}{8}$. In the centre is a hollow core, $2\frac{3}{4}$ in. diam. and $3\frac{3}{4}$ high, to prevent the pulp from collecting. The pan has four legs, which stand on a wooden stool; the latter carries a flat evaporating gas-burner for heating (not shown in the illustration).

The muller, Fig. 2 and 3, is of special construction. It is cast in one piece, as is the pan. The upper part, the driver, is slipped over the rotating shaft and fastened to it by a set-screw; it has a vent, Fig. 2, to prevent hot pulp from being sucked into the core; the spider has two legs only; the form of the muller-

*Trans. Amer. Inst. M. E., June, 1909.

plate and shoes is shown in Fig. 3; details of construction are given in Fig. 2. The shoes have the usual form of an oblique sector of a circle. One peculiarity of the shoe, seen in half-section on *D E* and in section on *L M* in Fig. 2, and in Fig. 3, is that the part outside of the muller-plate tapers from $\frac{1}{4}$ in. at the front to $\frac{7}{8}$ at the rear end, and thus assists in the formation of a pulp-current by raising the pulp while the muller is being rotated through the driving-shaft. This shaft, Fig. 2, is suspended from a bevel-gear with hub, fastened to it by a set-screw, and journaled in two boxes bolted to a wooden frame common to the 10 pans, Fig. 1. The bevel-wheel is driven by an adjustable bevel-pinion, which is thrown in and out of gear by a forked lever (stopper), the arms of which end in a grooved hub; the lever is supplied near the bottom with a hook, to be

tion of water during the grinding and amalgamating-periods, which has to be remedied by adding fresh water, in this case from a wash-bottle holding 500 c.c. The amount used is noted, as it gives an idea of the care with which the heating has been carried on. Allowing the pulp to become too thick requires an excess of water over the normal to thin it down in order that the desired current may be again established. In the experiments the water-additions ranged from 465 to 869 c.c. Water from the wash-bottle should be blown in small amounts against the side of the pan; it will loosen parts of the top of the charge which have adhered to the warm pan and become hard; the pulp-current then will carry them toward the centre and cause them to descend there. Scraping the sides with a spatula corrects the adhesion of parts of the charge, and has to be resorted

Fig. 2.

lowered into an eye (not shown) when the pinion is working.

The details of an operation may be given in connection with the plot in Fig. 4, which represents a series of 10 tests, in which the time of grinding was the variable, ranging from 20 to 100 minutes. The pan is first cleaned. For this purpose the muller is raised on the shaft and clamped, the wooden stool under the pan is withdrawn, the pan taken out and dusted, and the suspended muller freed from adhering particles of foreign matter. The pan is now put in place, the muller lowered, pressed down, and turned to and fro by hand and clamped. The necessary amount of water, 500 c.c., is charged, the muller set going, the lamp lighted, and the salt, 180 gm., added. The ore, 1800 gm., of 40-mesh size material, is fed in slowly, and the time of grinding counted after all the ore has been charged, namely, after about 5 min. On account of heating the pulp with a lamp to about 80°C ., there is considerable evapora-

tion of water during the larger part of a test, as repeated additions of water thin the pulp to such an extent as to spoil the current.

At the end of the grinding-period, the muller is raised $\frac{1}{8}$ in. previous to adding the quicksilver. In order to fix the distance, a pencil is held against the rotating shaft and a line marked off; the bevel-wheel is now thrown out of gear, the muller unclamped, raised, re-clamped, and set rotating again. A weighed amount of quicksilver, 150 gm., is then added during about 5 min. in a fine spray from a glass funnel on to the charge near the outer edge. The consistence of the pulp must be a little thicker than during grinding; the right degree will be determined by the manner in which the quicksilver is disseminated; this will be found in globules if the pulp is too thick, in fine particles if right, and will collect on the bottom if too thin.

In making a clean-up, the first step is to remove the tailing and amalgam from the pan. The muller

is stopped; a sheet-iron vessel, 18 in. square and 4 in. deep, having a thin coat of pitch and tar, is placed underneath the pan; the muller is again started, and first one litre of water added to thin the pulp, then two litres more in about 5 min., which causes a large part of the tailing to overflow into the vessel. The amount of water desired, and the time allowed for adding it, had been settled by experiment before

panning twice in a 16-in. gold-pan; the tailing goes onto the filter-cloth and drains over night, the amalgam, collected in a porcelain dish, is dried and weighed. The discrepancy in weights of quicksilver and amalgam in the table requires explanation. The combined weights of quicksilver fed, 150 gm., and silver contained in the charge, 5.449 gm., give 155.499 gm., while the weights of the amalgams recovered

show a range of from 156 to 164 gm. Part of this excess is due to a possible slight overweight in the quicksilver charged, part, however, to the presence of impurities in the amalgam. Thus, a partial analysis of retort-bullion gave: Ag, 51; Pb, 43.61; Fe, 5.12; Cu, trace; total, 99.73%. The 10 amalgams of a series of tests are placed separately in half-cylinder cast-iron vessels, transferred to a pair of retorts, and distilled in a two-muffle furnace, which is fired with soft coal; the muffles are 4 in. wide, 6 in. high, and 18¼ in. deep. Each vessel is coated with chalk, and receives a layer of paper before the amalgam is charged,

in order to prevent the retort-bullion from adhering to the iron.

The general arrangement of apparatus is clear from Fig. 5. It consists of two wrought-iron pipes, 3 in. diam. and 24 in. long, each closed at one end by a disc, ¾ in. thick, that has been welded in, and at the other by a reducing T, 3 by 3 by 1 in., and a reducing cross, 3 by 3 by 1 in., respectively, and

Fig. 3.

adopting this mode of operation. The rest of the pan-content is now transferred to a fibre pail holding about 2.5 gal., the pan and muller being scraped with a spatula and brushed with a dauber. The next step is the separation of the amalgam from the tailing and the recovery of the latter. The tailing collected in the iron vessel is transferred to a filter, which is a simple wooden frame, 18 in. square and of

Fig. 4.

1-in. section, with heavy unbleached cotton cloth spread over it and nailed fast on the under side. The 10 filters are soaked for several hours in water before they are put to use, in order to close the pores. Nevertheless, small amounts of slime pass through, which are caught with the filtrate in buckets and allowed to settle over night, when the clear liquid is decanted and the slime collected from each filter, dried and weighed.

The tailing and amalgam collected are separated by

joined by a 1-in. connecting-pipe; the T and the cross are closed by square-head screw-plugs. Into the lower retort is screwed the condenser, which reaches into a vessel filled with water.

The quicksilver is driven off in about 3 hr.; the water in the condenser has to be replaced at intervals; a continuous flow of water was found to be unnecessary. The retorts and the furnace are allowed to cool over night.

The morning after the run has been made, the

Fig. 5.

drained filters are placed on steam-tables to become thoroughly dry, and the retort is opened. In the afternoon, each student receives the tailing and the retort-bullion from his pan; he passes the tailing through a 40-mesh sieve to break up the lumps, samples down to 200 gm., crushes the sample through a 100-mesh sieve, and makes a duplicate assay; at the same time, he scorifies his retort-bullion and cupels it. By using a large muffle, $8\frac{1}{2}$ by 5 in., and 18 in. deep, a number of crucible-fusions can be made at the same time, and the work thus expedited. The re-

affects harmfully the pulp-current and flours the mercury, which increases the losses. Without a good current a satisfactory extraction is hardly ever obtained.

The following is a summary of a large number of tests made in extracting the silver from a single ore by raw-amalgamation in cast-iron pans of the construction given. They represent the first experiences of students in this kind of work, who, however, are familiar with assaying and panning. In the selection of samples only those tests have been omitted which in the class-conferences were decreed to be faulty for some well ascertained reason.

The ore is a silver-ore from the Palmarito Mining Co., District of Mocorito, Sinaloa, Mexico. An examination, aided by the microscope, showed that it was composed mainly of quartz and kaolinite, and contained besides some hematite, galena, pyrite, native silver, and cerargyrite. In the pulp, crushed by means of rolls through a 40-mesh sieve, were found particles of metallic iron. The ultimate analysis gave: H_2O , hydr., 0.07%; SiO_2 , 86.10; Fe, 6.68; Al_2O_3 , 2.66; S, 0.07; Pb, 0.28; Ag, 0.31 (98.1 oz. per ton); As, Sb, Cu, absent.

The rational analysis was determined by the following considerations: the Al_2O_3 was calculated as kaolinite (Al_2O_3 , 39.8%; SiO_2 , 46.3; H_2O , 14.9); the remaining SiO_2 was assumed to be quartz; the S not required by Pb to form galena was calculated as being bound to Fe as pyrite; metallic iron to the ex-

Fig. 6.

sults are handed to the instructor, who records the weights and assays.

The weights of tailing remaining on the filters range from 1775 to 1797 gm., equal to from 98.60 to 99.84%; those that passed through the filters weigh from 1 to 8 gm., equal to from 0.06 to 0.44%, which gives a loss in weight ranging from 1 to 20 gm., or from 0.06 to 1.11%. The weights of amalgam and retort-silver show some variations. The combined recovery in quicksilver from the 10 tests is high, 99.13%. In making up the silver-account, the tailing shows assay-values of from 13.92 to 16.86 oz. silver per ton. A pan was charged with 5.499 gm. of silver; this is the total to be found in the tailing and in the amalgam; the amount accounted for is seen to vary from 99.49 to 99.97%. The last two columns give the extraction in silver based upon the tailing-assay and upon the recovery in the amalgam. The former figure is, of course, the only reliable one, but the other column is added to bring out any contrasts which may exist. It is an accident that the figures of the two columns agree so closely; frequently considerable discrepancies occur, due to imperfect cleaning of the pan in a preceding test, or to hard amalgam adhering to the muller in one case and peeling off in another. Fig. 4, finally, shows graphically the extraction of silver as influenced by the time of grinding. It is seen to increase with the time of grinding from 20 to 60 min., when it reaches a maximum of 84.76%, and then to fall off. The probable reason for the diminished yield, after 60 min. of grinding, is the excessive sliming of the ore, which

Fig. 7.

tent of 0.10% was extracted by a magnet from the pulp; the remaining Fe was figured as hematite; of the Ag present, 0.02% was extracted by means of sodium hyposulphite and calculated as cerargyrite; the rest was assumed to be present in the metallic state. This procedure was believed to be warranted by the facts that As and Sb were absent, that more than 70% of the total silver was amalgamated in 20 min., and that more than 80 was recovered in the pan in the absence of salt. The rational analysis of the pulp thus gave: H_2O , hydr., 0.07%; quartz,

83.01; kaolinite, 6.68; hematite, 9.36; galena, 0.38; pyrite, 0.06; metallic iron, 0.10; cerargyrite, 0.03; metallic silver, 0.29; total, 99.98 per cent.

In the tests there were examined the effects of varying the addition of salt, the time of grinding, the time of amalgamating, and, last, the influence of an addition of blue vitriol. Previous experiments had shown that, with a charge of 1800 gm. of ore, 500 c.c. of water at the start gave a satisfactory pulp, and 150 gm. of quicksilver an amalgam of sufficient liquidity to reduce the loss in panning to a negligible

the presence of any salt whatever points to the supposition that a large part of the silver is present in the metallic state.

The extraction, as shown in Fig. 7, is seen to resemble very closely that which has been previously given in Fig. 4.

The data, plotted in Fig. 8, show clearly the rapid rise in the extraction during the first hour of amalgamation, and the small increase during the next half-hour, when a maximum is reached. The slight falling-off later on is to be attributed to the inevitable flouring of quicksilver in every amalgamation-process, with a consequent loss in silver.

The addition of variable amounts of blue vitriol to the pan, as shown in Fig. 9, has no beneficial effect whatever; on the contrary, the extraction decreases. The irregularities in the results are due to the amalgamation of copper, which causes losses in panning and in the subsequent assaying.

The inferences to be drawn as to the treatment of the ore are that, with a charge of 1800 gm., with an addition of 500 c.c. of water at the start and smaller amounts later on to keep the consistence of the pulp constant, and with 150 gm. of quicksilver, 6% salt, 60 min. grinding, and 90 min. amalgamating give the highest extraction.

The data, and the curves drawn from them, show that the results are satisfactory. Considering pan-amalgamation as a laboratory-experiment, it teaches in a simple, quick, and effective way, with an apparatus that is inexpensive, the importance of series-work in making an investigation, and the value of taking account of stock; it further gives results that can be used as the basis for work on a large scale.

MINERALS IN ALSACE-LORRAINE.

The total mineral production of Alsace-Lorraine has increased from 1,000,000 tons, valued at \$1,190,000, in 1872, when it became a part of the German Empire, to 15,500,000 tons, valued at \$16,660,000, in 1908. The output of coal and iron ore in 1908 is given as follows: Coal, 2,367,742

tons, valued at \$6,880,818; iron ore, 13,281,589 tons, valued at \$9,190,608. As compared with 1907, the output of coal shows an increase of 173,500 tons, valued at \$880,600, while the output of iron ore shows a decrease of 826,000 tons, valued at \$1,309,000. The decrease in production of iron ore is reflected in the decreased output of furnaces, Thomas raw iron being \$5,236,000 less than in 1907, although the production of foundry iron increased from 340,000 tons in 1907 to 403,000 tons in 1908.—*Daily Consular and Trade Reports.*

For connecting water or steam pipes it is useful to remember that graphite compounds make a tight joint; at the same time that it does not set as does red and white lead.

Fig. 8.

Fig. 9.

quantity. These three items, therefore, were kept constant in all the work, as well as the temperature, which was held at about 80°C.

The results, recorded and plotted in Fig. 6, show that, while the extraction in the absence of salt is high, it rises rapidly until 6% of salt has been added, falls with 10%, and rises again to practically the former maximum when 15% of salt has been charged. (The reason for the falling-off in extraction between 6 and 15% of salt is not clear, and will have to be looked into at a later date. The salt-series was the last one that was investigated; in the other tests the usual standard addition of 10% had been made; this explains the discrepancy between advocating 6 of salt and using 10). There is, therefore, no reason for going beyond 6%. The high extraction without

THE ARKANSAS DIAMOND FIELDS.

Written for the MINING AND SCIENTIFIC PRESS
By AUSTIN Q. MILLAR.

It is surprising to note the small number of geologists who have personally visited and studied the occurrences of peridotite, of the 'kimberlite' variety, in Arkansas which presents a field almost unique in the economic geology of America. This may be due to the prevailing impression that admittance has been denied to all comers, further augmented by frequent press-reports following that day in August, 1906, when a prospector picked up two glittering pebbles, subsequently identified as diamonds, and optioned his land. These parties sacredly guarded their rights to gain an opportunity to 'option' more, but the whole known area was not secured by them, nor were the further discoveries of diamonds limited to what these option holders would have the public believe was owned by them. There are three companies, one co-partnership and one individual holding, now owning rights to the diamond-bearing 'kimberlite' of Pike county. The total area is as yet unknown, but sufficient is known to warrant the statement that it will take many years to wash and search the disintegrated surfaces of the exposures before the more expensive treatment of the 'blue ground' becomes necessary. The mineral covers areas on sections 28, 21, and 14, in township 8 south, range 25 west, Pike county, Arkansas, easily accessible by way of Murfreesboro, the county seat, and now the terminus of the Memphis, Paris & Gulf railway.

The attention of these companies has been largely taken up by the exploitation of stocks, and no action has been taken to ascertain the average possible yield of diamonds. A total of perhaps a thousand stones, varying in size from minute fragments and crystals to six carats in weight have been found. These compare favorably in color, and average proportion of white stones, to those of the African mines, and in lustre are equal to the Brazilian diamonds.

The geology of the diamond-bearing mineral given by Branner and Brackett and later by Kunz and Washington, fails to note those characteristics of the rock proving its identity with the 'kimberlite'. This name was proposed by the late H. Carvill Lewis, of the Philadelphia Academy of Sciences, to designate that peculiar variety of peridotite more porphyritic than typical peridotites. The Arkansas peridotite is distinctly porphyritic, and inclusions of shale, sandstone, and metamorphosed rock are plentiful in the so-called 'green ground' and yellow ground of all the exposures.

Ilmenite, garnet, and olivine grains, and flakes of biotite, of the vaalite variety are not infrequently found in the disintegrated rock; also barite and magnetite. Blue ground cores show pyrite as a plentiful mineral. All these accessory minerals are prominent in the Kimberley mineral.

Beginning at the surface of an undisturbed area, or upon an area where erosion is not rapid, the 'black gumbo soil' is common.

Lying immediately beneath this covering, which seldom exceeds a few inches, the 'yellow ground' of the African miner extends to depths varying from 10

to 50 ft. or more, this being succeeded by a color-change to blue, the rock gradually becoming firm, and in greater depth extremely hard, yet when exposed to the weather it disintegrates quite rapidly, according to the depth from which it was taken. Intermixed with the yellow and blue ground of the Arkansas occurrences, masses of the hard, firm, fresh rock, like the 'hardibank' of the African diamond mines, is plentiful, and is especially noticeable on section 28, where a conical mass rises to a height of about 100 ft., apparently somewhat indurated by exposure; while other exposures of similar rock, occurring either as dikes or masses in the yellow and blue ground, show considerable effects of weathering. The disintegrated matter is indistinguishable from the disintegration of the blue ground. All this is in direct accord with the characteristics and peculiarities of the African kimberlite, which has produced practically all the diamonds of commerce for 35 years.

Considerable comment has been occasioned by local phases such as the 'green ground'. Much emphasis was given this feature of one of the Arkansas occurrences for the reason that the first discoveries of diamonds were made in this material. On one mine no diamonds have been found outside of a small area of moderately hard greenish-blue ground. Close examination reveals the fact that this covers a deeply eroded portion of the field, and its topography is such that erosion of the surface is constant and continuous, the yellow material being washed away to lower levels as fast as it is formed and thus constantly exposing ground, which, when moist, has the greenish cast that gave to it its name of 'green ground'. It is in reality the upper surface of the blue ground. When dry it is gray in color. Even this peculiarity of the Arkansas rock is not without its duplicate in Africa, for kimberlite, bearing diamonds has been found where only blue ground was exposed, the yellow ground being carried away as fast as it was formed.

On section 21, connected with the area of green ground mentioned, diamonds are found in the yellow ground and in the same disintegration on section 14. It is, therefore, obvious that the blue ground is the matrix and carrier of the diamonds from depth in Arkansas as in Africa, and the accompanying areas of 'hardibank' no doubt will in time prove to be 'horses'. The Arkansas deposits are assigned to a period preceding the Cretaceous. The economic importance of the Pike county kimberlite can only be determined by systematic work involving a large expenditure of money and time, but it promises well, and while too much attention has been given to the stock-selling side, legitimate mining is beginning to show favorable results.

Swedish iron exporters are jubilant at the prospect of lower duties on the raw product in the United States, and the prospect of German importers turning to new quarters for supplies is offset by the immediate opening of a new market in America. According to the latest freight quotations a rate of \$1.61 per ton from Lulea, Sweden, to Philadelphia, was made for shipments already negotiated.

SAMPLING METHODS.

By J. M. CAMP.

*Owing to the varying conditions under which iron ores must be sampled, both by the producer and the consumer, variations from any uniform procedure of sampling are inadmissible. The elements of time, size of shipment, kind of ore and other considerations are determining factors in the details of procuring the sample. Hence it is the purpose to render the following methods general in their scope, promulgating those ideas applicable in the broader sense to ore sampling, without attempting to prescribe for every varying and unforeseen contingency in the details.

All samples must be taken uniformly over the surface of the cars after being loaded, by taking a minimum of 12 places for wooden, and 15 places for steel

Fig. 1. Parallel System.

Fig. 2. Zigzag System.

load from all open-pit mines; a train consists of 40 to 45 of the 50-ton steel cars, or 60 to 68 of the 25-ton wooden cars. A moisture sample must also be taken for all the cars loaded at a shaft or stock-pile during each 10-hr. shift. Samples must be taken from three places on top of each car, as shown by Fig. 4. Care should be taken to secure the sample from well underneath the surface as soon as practicable after loading, maintaining the true proportion of lump and fine ore. The sample as taken must be immediately placed in a can with a tightly fitting lid, and brought to the crusher house. It is optional to take a moisture sample from the regular sample, provided it has been taken from well underneath the surface.

Cargo ores present the most serious obstacles to a uniform method of sampling. Boats vary in size from 3000 to 12,000 tons, with one or two decks, and in the number of hatches from 6 to 36, with widths varying from 12 to 24 ft. The grabs at the different unloading points vary in number, kind and size, and the rapidity of their operation. The ores vary from

Fig. 3. Rope-Net System.

cars, by either the parallel or the zigzag system. The diagrams (Fig. 1 and 2) illustrate these systems and show the minimum number of points where samples are to be taken. When lumps of ore occur at the designated points where samples are to be taken, small portions of each lump must be chipped off, about equal in size to the first joint of the thumb. When rock occurs it must be sampled as ore, that is, a proportionate amount of rock or off-grade material is to be taken, not equal in amount to the regular sample for the area covered by that point, unless the entire area is such off-grade material. Then the same amount of adjacent material must be taken, of ore or rock, equal in amount to the portion taken at each regular point.

The samples are taken with a garden trowel. Each 10 cars, either steel or wooden, must be combined, as a rule, into one sample; but less than 10 cars may be grouped. The weight of the sample must not run under 15 lb. for 10 wooden, and 20 lb. for 10 steel cars. Whenever very lumpy ore is to be sampled in the cars, the rope-net system is used, as shown in Fig. 3, which gives about 32 places on each car, the knots being 18 in. apart. In using the net system, if a lump of ore or rock comes directly under a knot, a piece should be taken about the size of the first joint of the thumb. If fine ore occurs under a knot, an equal amount is taken with the trowel. The rope-net system is used on the Marquette range on the hard, lump ore; also at the Soudan mine, Vermilion range.

A moisture sample must be taken for each train-

the very fine to all-lump, from the so-called mixed ores, such as the groups to the mixed cargoes, consisting of different ores in the same boat, and with different ways of loading the boats.

An excellent method of cargo sampling where the entire cargo will be represented, and particularly adaptable for fine ores, is called 'grab-sampling'. A sampler with a scoop attached to a handle of suitable length and holding a definite amount of ore, a quarter, a half, or a whole pound, takes a scoopful from each grab as it rises above the deck. The disadvantage of this system is its increased cost due to the extra number of samples, one being required for each grab during the entire time of unloading.

The general plan for the sampling of all cargoes is to first sample the tops of the piles, before the grabs have started to unload; this is called sampling of the cones. After the grab has removed from the hatch all the ore within reach, the exposed faces standing on each side are sampled; this method is known as face-sampling. Or when the latter practice is impracticable, owing to the operation of the grabs, then the method of rounds is followed. In sampling, a small shovel or garden trowel is used, the total length of which, including the handle, is 12 in., and it also constitutes a measure. It is the aim to take equal sized samples from each of the points selected. When lump-ore or rock is found at the point determined by the measure, a portion is broken off equal to the amount regularly taken. In the sampling of the cones, at a point midway between the side and the centre of the boat, directly under the edge of the hatch, the first sample is taken and sampling continued one shovel-length apart up the surface of the

*Abstract of paper published in *Electro-chemical & Metallurgical Industry*, February, 1909. Method used by United States Steel Corporation.

cone, over its apex and down the opposite surface to a corresponding point under the other edge of the hatch. This line is crossed from corresponding opposite points under the hatch, as shown in the following sketch, Fig. 5. Not more than one tenth of the total sample is to be taken in the sampling of the cones.

After a grab has removed from a hatch all the ore within reach and has moved to another hatch, the sampler should measure two shovel-lengths from the side of the boat and start up the exposed face of the ore, taking samples one shovel-length apart all the way to the top, using a ladder if necessary. The next

Fig. 4. Moisture Sample.

vertical line is measured four shovel-lengths from the first and the samples taken each shovel-length apart on this line as before, and so on for each succeeding line across the boat. This is repeated on the opposite ore face, and the entire procedure continued until the ore faces of all the hatches are sampled that the character of the boat and the operation of the grabs will permit. When a bulkhead occurs only the face opposite to it is to be sampled.

When the operation of the grabs makes sampling by the face method impracticable, or with boats having 24-ft. hatch centres, and decks furnish protec-

Fig. 5. Cone Sampling.

tion to the samplers, then sampling shall be done while the ore is being removed by the grabs. When 5 ft., or 6 ft. of the face of the ore has been exposed, the sampler shall enter the hatch and measuring two shovel-lengths from the side of the boat or edge of the face, take successive samples up the face one shovel-length apart. The next vertical line is measured four shovel-lengths from the first, and samples are taken all the way to the top as before, and so on across the entire face of the ore. This procedure is repeated on the opposite face, one third of the total weight of the sample to be taken in the first round. When all the ore within reach of the grab is removed, the second round is taken, using the measurements as above, and the remaining two thirds of the sample are secured. Part of the regular sample is to be taken for the moisture sample, and for the fineness sample when such is desired.

When the ore is received in cars the greatest possible number are represented in the samples, and not less than 10 equal-sized samples are taken from each car. When cars are loaded with fine ore, with the piles in opposite ends, at least five samples are taken from each pile, the first one at the apex of the pile, and the other four at points symmetrically arranged

around the sides of the pile, two thirds of the distance from the apex to the base of the pile or sides of the car. With cars loaded in the centre, the system is the same, except that the centre of the side of the pile lengthwise of the car is the first point, the other four being symmetrically arranged around this point. When the 10 points are located in a car, each of them is supposed to represent a definite area, equal to one tenth of the ore surface of the car. If the car contains all fine ore, then 10 equal-sized samples are taken, one from each of the points. If the car contains a mixture of fine and lump ore, with varying amounts of each in the areas included in the different divisions, then each area is judged separately and sampled accordingly. The fine and lump ore are taken each in its proper proportion, the former with the trowel, the latter being chipped, or selected small pieces being taken, each about the size of the first joint of the thumb. The combined sample of fine, chipped, and selected pieces from each area equals the amount taken were it all fine ore. If the content of the car is all lump-ore, the proper sized pieces are chipped from four or five lumps in each of

Fig. 6. Face Sampling.

the 10 areas, making 40 or 50 pieces from each car, the total amount of chipped pieces from each of the areas equalling the amount that would be taken were it all fine ore. All samples of fine ore are taken from well underneath the surface to obtain the ore in its natural state. A proportionate amount of the main sample is retained in a tightly closed can for the moisture determination.

In the preparation of the sample for analysis, the ideal practice is to crush and quarter alternately until the desired quantity with the requisite degree of fineness is attained. A more expeditious and equally efficient method, is to crush the entire sample to the desired degree of comminution, then reduce the quantity by successive quartering as before, until the desired amount remains. It should ever be the purpose to approach as closely as possible to either of these two methods in the preparation of all samples for analysis.

Briquetted fuel has been manufactured in foreign countries for many years. Railroads and steamship companies operating in certain countries are required to keep a reserve supply of fuel on hand, and briquettes are preferred because of their freedom from danger of spontaneous combustion, which frequently occurs in large piles of fine coal.

Zinc-oxide produced in the United States in 1908 amounted to 56,292 short tons, valued at \$5,072,460. This was a decrease of 15,492 short tons from the 1907 production. The average price in 1908 was \$90.09, and in 1907, \$90.47 per short ton.

VARA CONVERSION TABLE.

The accompanying table for converting *varas* into feet, prepared by Lee Fraser, is based upon the Spanish measure of that name, and the equivalence chosen by Mr. Fraser approximates that of the Burgos *vara* which is 2.742 ft. The importance of any such table is minimized by the difference in standards of measurement prevailing in the several Spanish countries. These differences are so great that one is tempted to risk a pun and affirm that the *vara* is a variable, and in truth its value has to be determined in each equation. In Mexico the *vara*, which now has no legal standing, was 36 Spanish inches. The Spanish inch, according to the best light we have,

SPIRIT LEVELING.

A recent publication of the U. S. Geological Survey (Bulletin 342) contains the results of spirit leveling done by the Survey in California for the years 1896 to 1907, inclusive, and forms a reference book of great value to engineers and surveyors. It comprises descriptions and elevations of bench-marks in 42 counties, which furnish vertical control for one-third of the State. The leveling since 1903 in the Sacramento valley was done in co-operation with the State. The lists are separated into two classes, precise and primary, distinguishing the degree of refinement in the method of leveling employed. The exact location of each bench-mark is described and its elevation

CONVERSION TABLE FOR VARAS AND FEET.
1 vara (castillian) = 2.7395 feet.

is equivalent to 0.9275 English inch. Therefore the Mexican *vara* would be 33.39 English inches, or 2.7825 ft. In San Francisco the *vara* is still used in certain districts, where 50 *varas* are taken as 137.5 ft., which makes the *vara* equal to 2.75 ft. The values in English measure of the *vara* in several of the Latin countries is given by Halse in his valuable 'Dictionary of Spanish and English Mining and Metallurgical Terms' as follows: Argentina, 2.843 English feet; Brazil, 3.624; Central America, 3.239; Chile, Peru, and Portugal, 2.780; Colombia, 2.624; Cuba and Venezuela, 2.782; Mexico, 2.75 (in which re-appears the value assigned to it in San Francisco); Paraguay, 2.833; Uruguay, 2.904. The Century calls *vara* "a Spanish-American linear measure," ignoring its Spanish origin, and strangely credits it etymologically to Chile, without mention of the derivation from ancient usage, when a twig served for a measure in Spain as three barleycorns did in England. In almost all the Latin countries the metric system is now the only legal one.

in feet above sea-level, carried out as a rule to three decimal, is given. This work fills a long felt want by surveyors and others in California.

Zinc smelting in Europe is now controlled by two groups of operators. The first group comprises 18 concerns, principally the zinc works of Upper Silesia and Westphalia, certain Austrian concerns, and several Belgian works. This group is organized as a German company designated as Zinc Hussen Verband. In Silesia the Heritier George van Geische Co. has remained outside the syndicate, although in many ways closely associated with it. The production of the first group has been limited for 1909 to 255,086 metric tons and for 1910 to 264,232 metric tons.

The second group comprises the zinc works mainly situated in Belgium, notably the Vieille Montagne Co. The production for this group is limited for 1909 to 174,519 metric tons and for 1910 to 175,919 metric tons.—*Daily Consular and Trade Reports.*

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Treatment-costs at the Homestake mine, in South Dakota, are: milling and amalgamating, 44c. per ton; cyaniding, 18, and slime-treatment and construction, 24. The total cost is, therefore, 86c. per ton. The mining costs are approximately \$2 per ton, which seems high on so large a daily output as 4000 tons.

Since the recent California mining act went into effect all notices of location of lode or placer claims, or tunnel or mill sites within this State must, within 30 days after posting the notice of location on the claim, be recorded in the office of the county recorder for the county in which the location is situated.

Roll-feed may be either 'free' or 'choke', that is, the feed may be so regulated that the material fed passes as rapidly as it touches the roll, or it may be fed slightly faster, so that the full crushing-capacity of the rolls is presumably availed of. Choke feed increases the friction and the wear, and is not as good practice as the accurately adjusted feed.

Sulphur occurs in Japan chiefly at Volcano bay, in central Hokkaido, and the Kuriles. The sulphur comes mainly from near Hakodate, but there are mines also near Kuchan in Shikibeshi, and at Ishikaridake, Mount Akan, and Shari. Some of the deposits yield sulphur almost as pure as that produced in Louisiana. The exports are about 30,000 tons per annum.

Angle of slope varies with the material, gravel standing, though not securely, at 40° (equal to a slope of 1¼ to 1), while sand will stand at from 36 to 38°. Wet sand will not stand at such steep slopes, the angle of rest flattening out to about 22°. A soil-covered hill with low brush to protect it from wash, seldom exceeds in steepness an angle of 37 degrees.

Barium carbonate is mined in the Thuringian mountains, Germany, and is known as witherite. The barium carbonate commonly shipped to the United States is an artificial product, obtained by the treatment of BaS with CO₂ gas, and boiling. The material so made is used for the manufacture of bricks of even color and of terra cotta; it is also employed in the glass and earthenware industries.

Saltpetre deposits occur in Chile throughout an area of 22,500 square kilometres, or 8687 square miles. This area is but 18 to 20 miles wide, and stretches along the Pacific Coast for over 450 miles. The deposits of *caliche*, or soda nitrate impregnation, are irregular, both as to extent and richness, but the total resources of the region are quite unknown. Estimates place the total available *caliche* at 340,000,000 tons, which would yield about 2,500,000 tons of saltpetre. At the present rate of exportation this quantity would last 136 years.

Quicksilver is reported from a point in British Columbia, occurring in small quantities in the gravel of a stream-bed. The geological formations adjacent are said to include schists and quartzites, overlaid at considerable altitudes above the creek-level by limestones. The statement is made that no mining has been done in the gulch, but this should be thoroughly verified before spending time and money in further search, since the quicksilver may have come from old workings. Prospecting might properly be done on the quartzite areas, and also in the limestone. The existence of native quicksilver in the stream-bed is no indication as to probable richness of any near-by deposit.

Thorium is obtained chiefly from monazite sand, which is found in the Carolinas, in Georgia, Idaho, Oregon, and in other States on the Pacific Coast. The content of ThO₂ in monazite sand varies from 0.01 to 7%. It is converted into the nitrate for use in making gas-mantles. The fluid used contains 99% ThNO₃, with 1% of cerium nitrate. The sands are first roughly concentrated in sluice boxes; the sluice-box product is then concentrated on Wilfley tables, and the latter concentrate is further cleaned by magnetic separators. The grade of material shipped carries from 98 to 99% monazite, which brings about 12c. per pound. Thorium is obtained as a nitrate in San Bernardino county, California, and is expected, shortly, to be available for the market.

Hardpan is defined as "the more or less firmly consolidated detrital material which sometimes underlies a superficial covering of soil." It is a term so general as to include many forms of deposit, being at one place the clayey material resulting from the washing down through the soil of the fine argillaceous particles, forming a dense sub-soil layer; at another place it may be a lacustrine deposit over which subsequent 'wash' has brought a soil; and it is sometimes a residual argillaceous layer formed on top of a decomposing rock. In engineering specifications it is unwise to attempt a definition of the term, but to indicate what is to be contracted for as 'hardpan' on the plans submitted.

Claims situated, as shown in the accompanying illustration, having one common corner, may have also a common monument or post at that corner.

The courts have held that a common initial or discovery monument for two claims is illegal, but that does not apply to other monuments.

Resolutions Adopted by the American Mining Congress.

(1) *Resolved*, That the President of the American Mining Congress appoint a committee of five members, who shall be known as the Committee on Revision of Mineral Land Laws, to whom shall be referred all literature, resolutions, and matters pertaining to this subject; that this Committee be authorized to submit its conclusions and recommendations to the President of this Congress, who shall transmit the same to the Sixtieth Congress of the United States; it being the sense of the American Mining Congress that a national commission be elected from the mining communities, in such manner and form as may be prescribed by the Congress of the United States, said national commission to prepare a revised code of mineral land laws, and report the same to the Congress.

(2) *Resolved*, That the State and county authorities in desert regions be urged to develop and safeguard desert water supplies, for the protection of life and health of miners and other travelers; and to this end erect suitable metal guide-boards, and provide for their protection under suitable laws; and further that the United States Geological Survey be authorized by means of specific appropriations, to co-operate, through the Water Resources Branch, with the local authorities, giving especial attention to the accurate location of desert water supplies on the public domain, their maintenance and preservation, and to the preparation of maps and reports, and the dissemination of information about them.

(3) *WHEREAS*, The general development of the commerce of the United States is important to the miner, as the increased production of minerals is vital to the commercial life of the nation; and whereas, a continually enlarging market is necessary in order to maintain the present increase of production of American manufactured products; and whereas, the increasing and ever fluctuating rate of exchange between this and silver-using countries appears to be working to the detriment of our trade with Oriental nations; now, therefore, be it

Resolved, That a committee of five be appointed by the President of this Congress, whose duties shall be to investigate the trade conditions existing between the United States and the silver-using countries, and report back to this Congress at its next session.

(4) *WHEREAS*, The production of gold and silver bullion in various sections of the United States is constantly increasing, and whereas, in many cases the nearest United States assay offices are situated at great and inconvenient distances from the points of production, and by this means many producers are put to great expense for the transportation of their product and long delays in receiving returns thereon; therefore be it

Resolved, That the American Mining Congress, in Goldfield assembled, herewith recommends to the National Government the establishment of United States assay offices, at such points as may be convenient for the receipt of bullion, and owing to the fact that bullion to the value of from ten to twelve million dollars per year is now passing through the city of Los Angeles, California, that city is recommended as one of the points especially covered by this resolution.

(5) To the Speaker of the House of Representatives and the President of the Senate: The American Mining Congress, in session at Goldfield, Nevada, again respectfully asks the Federal Congress to establish at its next session a National Bureau of Mines. An industry which yearly adds \$2,000,000,000 to the nation's wealth, which contributes 65% of the freight traffic of the country, gives employment to more than 2,000,000 men and serves as a basis of the nation's varied industries, is entitled to this recognition and aid from the Federal Government; while the waste of resources and loss of life in mining in this country are matters of serious national concern and deserve consideration and action by the Federal Government similar to that accorded to Agriculture and other great national

industries. The American Mining Congress urges that such action be taken without further delay.

(6) *Resolved*, That we recognize the value of the conservation movement to the mining interests, involving, as it does, the utilization without waste and the development free from monopolistic control, of the natural resources of the country, in land, water, forests, and mines, for the greatest good of the greatest number; that we also recognize the importance of the development of cheap water and electric power to the mining interests, and the importance of cheap water transportation particularly for the products of the mines, which are bulky and heavy and generally of comparatively low value; and we, therefore, endorse the movement for the development of the inland waterways of our country; that in aid of this, we favor the organization under the authority of Congress, of a national commission or board, composed in part of the chiefs of the scientific services of the country with a view to the formation and execution of comprehensive plans for the improvement and development of our rivers, including tributaries and source streams, not only for navigation, but also for the irrigation of arid lands, the drainage of swamp lands, the development of water power, the conservation of forest watersheds, and other related uses; and we favor the organization of similar commissions or boards, by the legislation of the respective States, with a view to co-operation between the nation and the States, and each acting within the limits of its jurisdiction.

(7) *WHEREAS*, The Federal Government, through the United States Geological Survey, is conducting investigations relative to the safety of mines, and those engaged in mining, which investigations are yielding results of great value, therefore, be it

Resolved, That the officers in charge of these investigations be asked to furnish the appropriate committees of the American Mining Congress such assistance as they can and as may be permissible under the statutes.

(8) *WHEREAS*, We deem it of the highest importance, not only for the Territory of Alaska, but also for the entire Pacific Coast and the American navy, that the valuable coal deposits in the Territory of Alaska should be opened without delay; and whereas, owing to the ambiguous provisions of Section 3 of the Act of May 28, 1908, wherein the titles to the land covered by claims taken, are liable to forfeiture to the United States if any of the provisions of said section are violated; and it has been found impossible to secure capital to develop the coal fields; therefore be it

Resolved, That the American Mining Congress in this twelfth annual convention assembled, does earnestly recommend: First. That the granting of patents to coal lands under the Act of May 28, 1908, be expedited. Second. That all claims located prior to November 12, 1906, by citizens of the United States for their own use and benefit, shall be speedily passed to patent thereunder. Third. That the said Act be further liberalized as to the area permitted to be grouped thereunder, and in such other manner as the Congress of the United States may deem wise, to the end that private enterprises may be encouraged and monopolistic control prevented. Fourth. That the third section of said act be modified in so far that the unlawful acts of the individual as contemplated in such act, shall in no event be sufficient to work a forfeiture of the patent issued to a company in accordance therewith; but that the unlawful act so committed should be dealt with and the individual be punished by fine and imprisonment, as in law directed, but this is not intended to apply to fraudulent entries. Fifth. That Congress be urged to set aside and reserve out of the unappropriated public lands in Alaska, an area of coal lands, sufficient to supply the quantity and quality of coal that may hereafter be needed for the uses of the Government itself. and be it further

Resolved, That a copy of this resolution be forwarded to the Honorable Secretary of the Interior and to the Senate and the House Committees on Public Lands.

(9) *WHEREAS*, The immediate development of the oil fields of Alaska has become a matter of vital importance to the commercial needs of the Pacific Coast; and whereas, the laws and regulations now in force have proven inade-

quate and inapplicable to meet the peculiar conditions surrounding the development of these fields; therefore, be it

Resolved, That the American Mining Congress in this twelfth annual convention assembled, urgently recommends to the Congress of the United States such immediate consideration and legislation as will encourage the speedy development of these fields. And be it further

Resolved, That a copy of this resolution be forwarded to the Honorable Secretary of the Interior and the Senate and the House Committees on Public Lands.

(10) WHEREAS, The law as applied to oil and placer claims in the Territory of Alaska, prescribing that annual assessment work be performed upon each claim to the value of \$100 per year, owing to the unusual circumstances, does not in the majority of instances, tend to the development of such claims; and whereas, the lack of adequate roads in the Territory of Alaska is a source of hardship and a handicap to mining development, of these resources; therefore, be it

Resolved, That the American Mining Congress in this twelfth annual convention assembled, does earnestly recommend to the Congress of the United States that the placer laws, so far as they apply to Alaska, be amended so that the owner of such claims may be permitted at his option either to pay into a special fund in lieu of assessment work, the sum of \$100 per year for each claim of 20 acres, or do the work itself and that the funds derived thereby shall be expended for the building of roads within the territory. And be it further

Resolved, That a copy of the resolution be forwarded to the Honorable Secretary of the Interior and the Senate and the House Committees on Public Lands.

(11) *Resolved*, That the President appoint a committee of three to co-operate with himself, in raising funds sufficient to enable the American Mining Congress to prosecute more vigorously and efficiently, the important work for the mining industry it is now undertaking to accomplish.

(12) *Resolved*, That a committee of five on legislation be appointed, the purpose and duty of which committee shall be to co-operate with the Secretary in securing the establishment of a National Bureau of Mines, and the enacting of such other Federal legislation as may be asked for in the resolutions passed by the American Mining Congress at this session.

(13) *Resolved*, That a committee of five be appointed by the American Mining Congress to consider and recommend such changes in existing Federal Statutes and Regulations, as will remove causes of friction and best promote friendly co-operation between the mining interest and the management of the National Forest; with a view to facilitate prospecting and mining within the national forests; that the Report of the Forestry Committee submitted to the Congress at this session, be submitted to the above committee for its information and consideration, and that the Forestry Committee be discharged.

(14) *Resolved*, That the President appoint a general committee of seven, including the Secretary, with a view to increasing the membership of the Congress.

(15) *Resolved*, That the American Mining Congress condemns all forms of fraudulent mine promotion and dishonest stock flotation, as being detrimental to the proper and legitimate development of the mining industry; that we favor measures for the exposure of fraud; and that we urge upon the legislature of the various States and Territories the enactment of stringent laws for the protection of investors, realizing as we do that a wise and judicious regulation will injure no one, and will be beneficial to the mining interest as a whole.

(16) WHEREAS, It is the sense of the American Mining Congress that the creation of a great merchant marine will benefit the mineral industry by expanding markets, and by attracting foreign ores, mattes, and other metallic products to this country for reduction by reason of the advantages of ballast rates which are afforded for such products when a large shipping exists; and whereas, such imports would enlarge the opportunities for the investment of capital in

smelters and refineries, and thereby provide a wider and more advantageous market for domestic ores and mattes; therefore be it

Resolved, That the American Mining Congress respectfully requests the President of the United States to make known to Congress the sentiment of this organization in favor of stimulating the growth of an American merchant marine by suitable legislation.

Pacific Stem Guides.

The D. D. Demarest Co., 503 Market St., San Francisco, is making a simple efficient device to replace wooden guides on stamp-mills. It consists of cast-iron frames, fitted with removable cast-iron linings. The linings are the only parts subjected to wear, and may be easily and cheaply replaced as they wear out. The linings fit into tapered sockets of the frame, and require no bolts, keys, or set-screws to hold them in place. Any one lining may be replaced without hanging up the other stamps in the battery. One point worth noting is that stems of different diameter may be used in the same battery simply by using the proper-sized liner. It is claimed that batteries equipped with these guides will require less attention and time in adjustments and lubricating than those having wooden guides, and will therefore leave the mill-man more time to devote to his plates. Circular No. 27 has just been issued, and it describes these guides in detail and gives a number of illustrations. The D. D. Demarest Co. also manufactures rock-drills, lubricating stop-cocks, drill sharpeners, Cornish pumps, air-compressors, and can furnish all kinds of mining and milling machinery.

Commercial Paragraphs.

The HUTCHINGS safety mine-cage device was placed on exhibition at Goldfield during the meeting of the American Mining Congress by G. B. Suter, of Denver, Colorado.

The GENERAL ELECTRIC Co., advises that it received grand prizes in every class of electrical apparatus in which an exhibit was made at the Alaska-Yukon-Pacific Exposition.

The ALLIS-CHALMERS Co., Milwaukee, announces that H. C. Holthoff, for the past two years manager of the Mexico office of that concern, has been made manager of the mining machinery department, with headquarters in Milwaukee.

HARRON, RICKARD & McCONE have removed their San Francisco office to their new building at 139-149 Townsend street. The location is easy of access and the building excellently adapted to the growing business of this pioneer concern.

The MINE & SMELTER SUPPLY Co., New York, announces that W. L. Loveland, lately manager of the mining machinery department of the Allis-Chalmers Co., has accepted a position as general manager for the former concern, with offices in New York.

WILLIAM H. WONFOR, of the Wm. POWELL Co., Cincinnati, Ohio, is leaving for a trip to Cuba, Spanish West Indies, and Mexico. This trip is in connection with the export business of the Wm. Powell Co., manufacturers of valves and steam specialties.

NORTHWESTERN UNIVERSITY has made an appropriation to equip an ore-testing laboratory. The old gymnasium has been remodeled and the front section will be occupied by the mineralogical department under the direction of D. F. Higgins. The metallurgical laboratory in the rear section will be made under the direction of W. H. Coghill.

THE GALIGHER MACHINERY Co., Salt Lake City, successors to the Utah Mining Machinery & Supply Co., announces that it is manufacturer and agent for the United States, Canada, and Mexico of the Isbell vanner. The announcement is accompanied by an illustration showing the general appearance and some of the constructional features of the new machine. A fully illustrated bulletin giving data from actual operation is promised for the near future. The Galigher Machinery Co. will be glad to receive the names of any interested persons, to whom the bulletin will be sent when issued.

EDITORIAL.

B IENVENIDO, Señor Don Gaspar de Portolá! Hace largo tiempo que sus pies no han pisado el suelo de San Francisco. Con gran gusto entregamos á V. las llaves de la hermosa ciudad. Tuvo V. que descubrirlo de nuevo. Después de haber sido destrozada por temblores y quemazones, las obras de varias generaciones quedaron como si nunca hubieran existido, pero la energía inagotable de los hombres del occidente ha resuscitado la ciudad de las cenizas, y ahora ofrecemos á su vista, Don Gaspar, algo mas grande que lo anterior. Situada en la Puerta de Oro, esta ciudad tiene probado su poder de continuar su carrera de conquistador, y mira ál través del Mar Pacifico en donde va á ejercer dominio por el arte de la paz. Viva Don Gaspar! Viva San Francisco!

K OYUKUK district, in Alaska, is attracting renewed attention. The output for the past season is estimated at \$350,000. New discoveries have been made on Nolan creek and so many men have been attracted to the area that a new town, Wright City, has been founded.

P ARACALE and Benguet districts continue to attract attention in the Philippines. Within the last three months more than three million dollars has been raised to develop the Paracale placer and quartz deposits. New Zealand capitalists were the pioneers in this district, but Americans and Englishmen are beginning to invest. Both districts are in a healthy condition and are producing at a good profit.

W INTER is at hand in the Far North. The *Victoria*, sailing from Seattle last week, is expected to be the last boat of the season to Nome. Regular communication will, however, be kept up by way of Fairbanks and the winter trail. Work on the Copper River railroad is not expected to stop and the *Leelanaw* is now loading with railroad material for Cordova. Bridge building will, in fact, be facilitated since false-work can be erected on the ice. Winter has largely lost its terrors in Alaska since trails, telegraphs, and steamers have become common.

GREETING, personal and cordial, between the chief executives of the neighbor Republics of North America, took place at El Paso and Ciudad Juarez on October 16. Courtesies were exchanged on both sides of the Rio Grande, and good-will was stimulated by a banquet in the Custom House in the Mexican city. A smile springs to the lips on reading that these chiefs of two great nations feasted off the elaborate silver service left in Mexico as a relie of

Maximilian's short-lived monarchic splendor. There was a touch of sardonic glee in that, perhaps more significant than was intended. Nothing more spectacular than the simple impressive fact of personal exchange of courtesies between Presidents Diaz and Taft occurred. No play upon popular passions was attempted; no empty words of flattery were expressed to tickle the ear. Dignity marked the entire proceeding, and the serious exchange of views was behind closed doors. For once Democracy demonstrated that it had not forgotten human nature in pretended open speech for the deified people. In fact, the signs of the times are that shirt-sleeves diplomacy is out of vogue, and Uncle Sam discreetly puts his finger on his lips upon occasions of prudence. The meeting on the Rio Grande is the most notable that has ever taken place between presidents. In 1879 President Hayes entertained President Barrios of Guatemala; in 1886 President Cleveland received President Zalvidar of Salvador; President Iglesias of Costa Rica paid his respects to President McKinley in 1895; and President Roosevelt visited his protégé, President Amador, at Panama in 1906. These were interesting incidents, but the meeting of Presidents Taft and Diaz looks to the strengthening of cordial relations between the United States and Mexico at a time when important developments, political, commercial, and probably diplomatic, are in prospect.

ATENTION was called last week by our Mexican correspondent to the placing of the order for a notable hydraulic excavation plant by the Government with Henry R. Worthington, of New York. The significant point is that the order went to New York. Government engineers in charge of work on the Panama Canal visited California to inspect hydraulic mining methods; they perceived the possibility of adapting similar methods to excavation on a portion of the Canal prism; such adaptations had long been made in the West for removing dirt to construct earth-dams, and lately large areas of hill-ground in Seattle were levelled by these means. Western engineers and manufacturers had co-operated for decades in developing hydraulic mining appliances, and the world has drawn its models from the practice worked out chiefly through Californian experience. But when it came to placing an order the Government perforce bought in the cheapest market. This is said in no spirit of local interest; it is instructive through the light which it sheds upon the difference between commercial conditions on the Atlantic and Pacific coasts. The basal industries in the East are more cheaply conducted, and the Western industry has grown to a large extent through taking part of the trans-continental freight rate as local manufacturer's profit. The Pacific Coast has no iron furnaces, no steel-making plants, no copper refineries; it is not yet able to compete with the Easterner nor the foreigner. But it possesses the raw materials; there is no lack of iron ore, though much of it has been bought and held for the future by Eastern and Middle-West corporations; there is available copper, coal, oil, and cheap hydro-electric power. The elements are here, and if California means to reach over-

sea in commercial conquest it behooves her people to seriously develop the fundamental industries on which alone a great trade can be built.

THE resolutions of the American Mining Congress, which we published last week, will repay careful reading. They represent the sifted and condensed opinion of the thoughtful members and delegates who met at Goldfield. Collectively, they constitute the program and platform of that organization for the next year. The breadth and conservative character of the resolutions is striking. Amendment of the mining law, creation of a Bureau of Mines, establishment of additional assay offices, approval of conservation, better legislation for the Alaska coalfields, aid to the merchant marine, and other equally important subjects are treated. A marked feature of the present plan of work is the creation of committees to study and report on various subjects, such as the relations of the Forest Service to mining claims, the possible larger use of silver, the prevention of mine accidents, etc. All this denotes growth from the time when the most inspiring speeches related to the next place of meeting and the election of directors. It indicates a welcome indisposition to act before study, and seems likely to result in resolutions which will stand criticism. Nothing truer was said at Goldfield than the remark of Mr. J. H. Richards, in the course of his presidential address, that the influence of the Congress depends upon the honesty and intelligence of its members. The new president, Mr. E. R. Buckley, is a mining geologist of distinction who has served faithfully as vice-president and is thoroughly informed and in harmony with the best ideals of the organization. Everything points to continued growth in influence and power of the American Mining Congress.

Mine Inspection Again.

Mine inspection is a subject which is just now attracting considerable attention. In California last winter a proposed system of inspection was defeated. In Arizona an excellent commission has been appointed, with Mr. Will L. Clark as chairman, to draft a mining code and submit it to the next session of the Territorial Legislature. This commission has already prepared a first draft and it is now being submitted for amendment to experienced critics both within and without the Territory.

In Illinois a similar commission has been constituted, and it is, perhaps, expressive of the larger view which is coming to be common, that the body includes representatives of the miners' and operators' organizations, of the mine inspection service, of the State University and of the Technological Branch of the United States Geological Survey. A commission including Mr. John Walker, Mr. G. W. Traer, Mr. Richard Newsam, Mr. H. H. Stock, and Mr. J. A. Holmes, to name only a few of its members, shows no lack of talent. This action of the General Assembly of Illinois, in handing a technical subject over to a competent commission for advice, is in striking contrast with the defeat by the United States Congress of the bill for a Tariff Commission.

In the meantime the mine inspectors themselves

are not idle. Their new and excellent organization, the Mine Inspectors' Institute of America, has appointed a committee to collect the mining laws of the various States as a first step toward a common code, if that prove feasible in whole or in part. They have wisely decided that the laws of foreign as well as American States should be taken into account, and at their request Mr. J. W. Paul, of the Technological Branch of the United States Geological Survey, himself formerly chief inspector of West Virginia, is now collecting and codifying the laws relating to inspection in coal mines. This is a most useful work; one sure to result in much benefit. We regret that there seems to be no legal authority for the Geological Survey to undertake a similar compilation of inspection laws as they relate to metal mines. Since, however, during this Administration all acts are to be "well buttressed by law" we can only hope that Congress will give the specific authority to some proper branch of the Government service this winter. The need of greater uniformity in the State inspection laws is urgent, and a general report on the subject by an impartial Federal authority, with possibly a model law for Alaska and the Territories, would, we believe, prove as stimulating to correct local legislation as did the National Pure Food Law.

Genesis of Petroleum.

The subject of the origin of oil and related natural hydro-carbons has attracted much attention in recent years. A distinct reaction against the time-honored theory which attributed their derivation to the decay of organic matter buried in the course of laying down the sedimentary rocks has occurred. To Mr. Eugene Coste's vigorous, almost polemic, writing is mainly due the renewed interest in the long dormant theory of the inorganic origin of petroleum. Mr. Coste has raked the records for all facts bearing against the organic hypothesis and favorable to the inorganic. If it be objected that his citations have not always been well chosen, and in fact have been so used as to obscure and sometimes distort the description of the original authors, it may at least be said that he has brought together a startling array of instances of the association of petroleum with igneous rocks. He has lately received support from an unexpected source. Mr. G. F. Becker has attacked the problem with his usual acumen, and, while he cautiously refuses to commit himself concerning the relative quantitative importance of the organic and inorganically derived petroleums, he evidently considers the latter to be worthy of much larger recognition than they so far have received. We believe that Mr. Becker's major contribution to the subject consists in pointing out the possibility, or probability, if you wish, of the derivation of hydro-carbon compounds through the action upon terrestrial iron of ammonium chloride, such as is given off by volcanoes. The details of Mr. George Steiger's experiments, made for Mr. Becker, are promised later, and will be read with much interest. As a result of this work we are no longer restricted to the action of water on natural carbides if we seek an inorganic origin for

oil. Mr. Becker's second point, that there is a coincidence between the occurrence of petroleum and magnetic disturbances, does not seem to us so well taken. The economic importance of such a relation, if it exist, is obvious. Its explanation would doubtless lie, as he suggests, in the relation of both to masses of minerals or rocks possessing sensible magnetic attraction. We are not, however, impressed with the coincidences, at least as shown by the map which Mr. Becker has published. We find it particularly difficult to see the "strong deflections of the isogonal lines" which "accompany the chain of hydro-carbon deposits" in California, and to us the rule seems poorly sustained in the other great oil-fields lying in Oklahoma and Illinois. In the coastal plain area of Louisiana and Texas, again, the lines, as shown on the map, do not seem to conform to the theory. We understand that detailed observations in certain Louisiana districts do show the required coincidence between local magnetic attraction and the occurrence of oil, but in our own experience perhaps equally striking coincidences between local attraction and local illiteracy have been observed in southern Indiana. This is not said in any jesting spirit, but to emphasize the fact that argument based on coincidence needs many and striking examples to give it weight, and, in our judgment, that is exactly what is lacking in the present case. Hence the conclusion that "Henceforth no geological theory of petroleum will be acceptable which does not explain this association" is not fully substantiated. Mr. Becker has conferred a benefit in calling attention to the possibilities and in offering a reasonable hypothesis to account for them. It is worth perhaps what it will undoubtedly cost in the assistance it will give the sharpeners who trade on the ignorant in the locating of oil wells; but it is well not to overestimate the validity of a new hypothesis.

As to the main question of the origin of petroleum, there is much yet to be said on both sides, and for the present it seems well not to be too ready to release the old and grasp the new. The argument for organic origin rests on a well ascertained body of fact, both experimental and observational. The theory accounts for the fact that all large pools so far discovered are in sedimentary rocks, and reasonably near possible sources of organic origin. It offers also an explanation for the association of petroleum with rocks of a particular age in each geologic province; such as the Trentonian rocks of Ohio, Indiana, and neighboring States, the Mississippian and early Pennsylvanian beds of Ohio, Indiana, Illinois, Kansas, and Oklahoma, and the Miocene in California. This association is close and well established, and finds a ready explanation in paleogeography. To the objection that decay of organic matter produces methane alone, it is needful only to call attention to the action of putrefying bacteria. Thanks to the excellent work of Mr. David White, these have been shown to be present even in the identical oil-bearing shale near the base of the Trenton, which is a not improbable source of the Trenton oil. The whole subject demands additional study, and in the meantime our enthusiastic friends must pardon us if we counsel them to make haste a bit slowly.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

W. F. STEVENS was in San Francisco.
R. F. GIBSON has taken an office in Los Angeles.
EDWIN J. COLLINS, of Duluth, is at Globe, Arizona.
GEORGE OTIS SMITH was in San Francisco this week.
E. F. BURCHARD has been at Bismarck, North Dakota.
C. V. CRAIG has gone to Guadalupe, Zacatecas, Mexico.
E. C. KNOWLES, of Deadwood, S. D., is in San Francisco.
E. D. LIDSTONE, of Cordova, Alaska, is in San Francisco.
D. G. DAVIES has gone from Spokane to Joseph, Oregon.
FORBES RICKARD is examining mines at Rhyolite, Nevada.
BOND COLEMAN has gone from Miami to Kelvin, Arizona.
W. O. CROSBY has been at Oroville and is in San Francisco.
J. D. WINTON has returned to San Francisco from Nome, Alaska.

HUXLEY ST. J. BROOKS is in Costa Rica on professional business.

V. P. STRANGE has returned from Missoula, Montana, to Salt Lake.

WALTER F. LAWRY, of Sydney, Australia, passed through San Francisco.

W. E. DEFTY is engaged in making examinations in Pinal county, Arizona.

C. HENRY THOMPSON has returned to Los Angeles from Durango, Mexico.

A. W. SCOTT, of the Scott Mines Co., has returned to Salt Lake from Alaska.

JAMES P. GRAVES, president of the Bingham Mines Co., was at Salt Lake last week.

FRANK McHALE has opened a technical book-shop at 26 Cortland St., New York.

ROBERT R. HEDLEY has removed from Sudbury, Ontario, to Nelson, British Columbia.

LANE C. GILLIAM has returned to Seattle from Alaska. He will go to Los Angeles, November 1.

ARTHUR H. LAWRY has sailed for Nicaragua. He becomes assistant to C. S. Herzig at La Libertad.

F. H. MASON, after a long sojourn at Paso Robles for his health, has improved, and has gone to San Diego, California.

C. L. CONSTANT, JR., is making an extended professional visit to the mining sections of Ontario and eastern Canada.

LLEWELLYN HUMPHREYS, consulting engineer for the Gunn-Thompson Co., was recently at Yerington, Nevada, and San Francisco.

U. S. GRANT and a party of students from Northwestern University have been visiting the Wisconsin-Illinois lead and zinc fields.

WERNER ZIEGLER, formerly with the Ohio Copper Co., of Utah, is superintendent of the Sunbeam mine and mill, Custer county, Idaho.

J. H. WINWOOD and H. L. CHAMBERLIN, of Salt Lake, will be engaged the next month on Government land surveys in Washington county, Utah.

JOHN R. FREEMAN and A. P. DAVIS have been visiting Oroville and have gone to La Grange. They will later visit the Los Angeles Aqueduct.

L. VOGELSTEIN & Co. send the following figures of German consumption of foreign copper for the months January to August 1909:

| | Tons. |
|------------------------|---------|
| Imports of copper..... | 109,334 |
| Exports of copper..... | 5,289 |

Consumption of copper..... 104,045

as compared with consumption during the same period in 1908 of 101,945 tons. Of the above quantity 100,192 tons were imported from the United States.

R. B. LAMB, of the C. L. Constant Co., is leaving New York on a prolonged professional tour of the Western mining sections.

The SAN FRANCISCO SECTION of the Mining & Metallurgical Society of America held a meeting preceded by dinner in the Fish Room of the Bismarck Cafe, Friday, October 22.

General Mining News.

ARIZONA.

COCHISE COUNTY.

The shaft of the Empire Copper Co., at Dragoon, is down 90 ft. A body of malachite ore has been recently opened and it is understood that the company will install a compressor and hoist.—The shaft of the Keystone, at Johnson, is down 40 ft. Some black oxide ore was crossed by the incline.—The Arizona Shipping Mines Co. has taken over the Neale claims and is preparing to sink a shaft on the property.—The smelter of the Arizona United Mining Co., at Johnson, which was blown-in recently, is making matte that runs 55% copper. The shaft is down 750 ft., and a large body of low-grade copper is blocked out.—The California & Paradise Mining Co. was organized in Bisbee to take over the Leadville property in the Paradise district. W. V. Richards, of Bisbee, will be in charge of the work.—The adit on the Sunflower claim of the Duncan group, at Paradise, cut a body of copper ore when in 425 ft. The vertical depth is about 125 ft.—About 1 ft. of the ore in the 4-ft. vein opened by the cross-cut from the shaft on the Doran & Gallagher property is of shipping grade. On a lot sent to the El Paso smelter the assay was 31% zinc, 21% lead, 20% sulphur, 3% iron, with 8 oz. silver.

GILA COUNTY.

The grading for the concentrator of the Miami Copper Co. has been completed and the construction of the foundations for the first unit of the plant is well under way. A new double drum hoist is being installed at the No. 4 shaft, and a 1000-ton pocket cut at the 420-ft. level. The company put on sale a number of lots in its townsite and it is estimated that \$50,000 worth of property changed hands the first day of the sale.—The smelter of the Arizona Commercial Copper Co., near Globe, was blown-in about the middle of the month. It has a capacity of 500 tons per day, and the company has a large supply of different fluxes on hand so it can treat any class of commercial ore that may be shipped to it. Most of the ore on hand has been taken from the Eureka shaft, which has now been drained below the seventh level. Drifts have been started in the orebody.—Three machine-drills have been added to the equipment of the National Mining Exploration Co., at Globe, and the company plans to double the capacity of its steam plant in the near future. The Williams shaft is down 250 ft. in a diabase that contains considerable iron. The shaft will be continued to the 500-ft. level before any lateral work is done.—At the Live Oak property the company is confining the work to development on the 200 and 300-ft. levels. The management estimates that there is 500,000 tons of ore opened that will average 2½% copper. M. E. McCarthy is manager.

MOHAVE COUNTY.

Denver capitalists have secured a bond on the Witherlay property, 12 miles east of Planet, and will sink a 500-ft. shaft. John Witherlay, the owner of the property, has taken a bond on the Concho group in the White Picacho district.—The Nevada-Arizona Mines Co. has commenced grading for a 60-ton mill at its mine east of Hackberry. Two shafts have been sunk opening the vein to a depth of 250 ft., and an adit started that will give 500 ft. of backs. The vein is 8 ft. wide and the ore free-milling. T. J. Grant is superintendent.—Newton Evans and associates, of Los Angeles, have purchased the railroad that the Mohave Gold Mining Co. built several years ago, and will tear up the rails and build a spur from the Swansea road to the McCracken mine.—At the Horseshoe mine, near Cerbat, the shaft is down 275 ft. A station will be cut at the 350-ft. level and a cross-cut run to the vein.—The Arizona Gold Mines Co. is having its property east of Kingman surveyed for patent. The claims include the Bi-Metallic group.—One carload per day of 47% zinc ore is being shipped from the Golconda mine in the Cerbat district. An adit is to be started shortly that will intersect the vein at a depth of 350 ft.—The suit of the old Blue Ridge stockholders

against the Tom Reed property has been settled and the Hammond interests are to take over the property.

YAVAPAI COUNTY.

Two new dredges are to be built on Lynx creek in the Big Bug district by the Speck Mining Co., and the Prescott Dredge Mining Co., the design and construction of the machines being in the hands of the Snyder Iron & Steel Co., of Kansas City. M. L. Buckley is manager of both properties.—A carload of cobalt and nickel ore from the Red Bluff group, six miles east of Dewey, has been shipped to the reduction works at Perth Amboy. T. C. Jordan, the manager of the property, will visit the plant to determine the most advantageous method of handling the ore.—The mill of the Mount Elliot Consolidated Mining Co., near Big Bug, has been started and ore is being drawn from the 530-ft. level of the mine.—The shaft of the Pick & Drill mine has been re-timbered and work started on the vein at the 250-ft. level. S. J. Gnash is manager.—Thomas McSherry is opening a 4-ft. vein on his property in the Santa Maria district, 18 miles northwest of Hillside, that assays from \$16 to \$100 per ton.—The cyanide plant at the Alaska mine, in the Congress district, will be completed this month, and will be put in operation at once. D. J. Sullivan is manager.

YUMA COUNTY.

F. A. Crampton has been appointed manager of the Arizona Copper Belt Co.'s mines in the Black Rock district, and work will be resumed on the construction of the mill being erected on the property.—The Vulcan No. 2 shaft, of the Daly Mines Co., operating near Bouse, is down 40 ft., and has opened several bunches of carbonate ore. The shaft is being sunk on a limestone contact.

CALIFORNIA.

AMADOR COUNTY.

(Special Correspondence).—A 19-ft. body of milling ore has been cut on the 1700-ft. level of the Bunker Hill. A drift will be run from the 1900-ft. level to cut the vein, and if it proves satisfactory 20 stamps will be added to the 20-stamp mill. September 15 the company paid its 37th consecutive monthly dividend, and increased the rate from 5 to 6c. per share.—Rapid progress at the South Eureka is being made with grading and construction for the new 20-stamp battery.—The Defender has greatly curtailed operations and suspended all work at the recently completed cyanide plant. It is reported that the methods of treatment were not adapted to the ores.—Litigation between the former and present owners of the mines controlled by the California Consolidated Mines Co., has been started, and the case will shortly come up for trial in the Superior Court. The former owners claim that the California Consolidated Co. agreed to discharge certain liabilities against the company, but have failed to do so. The company controls the Wildman, Mahoney, Keystone, and other properties near Jackson. No work has been performed at the Wildman or Mahoney for several months. At the Keystone operations were recently resumed after several months' idleness.—The Kennedy is producing steadily and sinking the shaft below the 3500-ft. point.—The Kennedy Extension is repairing the old shaft and preparing for active work.

Jackson, October 18.

PLUMAS COUNTY.

(Special Correspondence).—An asbestos claim has been located by local men near the Spring Garden tunnel of the Western Pacific railway, and development has been started.—It is reported here that the Plumas Mohawk has passed into the hands of strong Eastern interests, and work on a largely increased scale will be commenced shortly.—The Northern California Mining & Development Co. has started work on several placer and quartz properties in the Quincy district.—The copper deposits, near Beckwith, are receiving considerable attention. Several promising claims are being prospected and good-grade ore opened.—San Francisco people have taken over the Gunsner property, on the north fork of the Feather river. Owing to its distance from transportation points developments have been restricted. It is reported that a steam shovel or light dredge

will be installed.—Nevada mining men are opening numerous properties in the Genessee district. The ores carry copper and gold.

Quincy, October 18.

SHASTA COUNTY.

The new span in the bridge of the Sacramento Valley & Eastern Railroad Co., across the Sacramento river above its junction with the Pit, has been completed. This road handles the supplies of the Bully Hill Mining Co., at De La Mar and Copper City, so the work was hurried to complete the span before the high-water season.—The Bullychoop mine, in the Bullychoop mountains, west of Redding, has resumed operations. The ore at the Bullychoop is base and the tailing contains much of the precious metal in spite of the efforts of the company to make a complete saving. There is a 30-stamp mill on the property which is managed by G. E. Beck.

SIERRA COUNTY.

The South Fork adit at Forrest cut a vein supposed to be the extension of the famous Tightner vein. Fred W. Kuhfeld is superintendent.—The English company that is operating the Bunker Hill and Four Hills groups under bond is negotiating for the Phoenix mine near Sierra City. The Phoenix is equipped with a first-class surface plant and has been started several times lately, but has been closed on account of poor financial condition of the operators.

TRINITY COUNTY.

The tunnel of the Trinity River Tunnel Mining Co., near Lewiston, has been completed and four turbines set in place at the power house. The tunnel has a capacity of 26,000 miners' inches of water, and with the machinery has cost the company approximately \$125,000. It is 1350 ft. long and drains one mile of the channel. The gravel will be washed from the bedrock by hydraulic giants and raised to the sluice boxes by hydraulic elevators and electric shovels.—The company operating the Headlight mine, near Trinity Center is planning to erect a mill at the property in the spring. There is a large body of low-grade ore in the mine that has been considerably prospected.

COLORADO.

GILPIN COUNTY.

At the Iroquois property, in the lower Russell district, the vein has been opened on the 80, 220, and 320-ft. levels, the ore averaging about \$18 per ton. On the recent excellent showing in the mine the company is preparing to install a power plant and machine-drills.—Rooney & Co., operating the Forks mine, on Quartz hill, under lease, have been forced to abandon the lower levels temporarily on account of the heavy flow of water, and are working on a small vein of lead ore on the 200-ft. level.—The return on a shipment of ore from the Hall mine, in the Russell district, to the Modern smelter, was satisfactory and the company is preparing to ship regularly.—Pool & Co., operating the West Notaway mine, have commenced shipping copper ore from the 400-ft. level.—The Cashier Gold Mining & Reduction Co. has installed an 80-hp. boiler at its property, near Russell, and is shipping the high-grade smelting ore. William Auger is manager.

GUNNISON COUNTY.

Ruben Jones has secured the Revenue mine, at Ohio City, and will equip the property with a complete surface plant.—G. M. Lyons, secretary of the Grand Prize Mining Co., at Ohio City, has purchased the Mono and Chloride groups of claims and will drive a long adit from Jones gulch to prospect the properties.

LAKE COUNTY.

Green Brothers, leasing the Little Ellen mine near Leadville, opened an orebody that assays \$60 per ton on the contact that crosses the property.—At the Wall Street in the same district the shaft is down 350 ft., and the company is to install a heavier hoist and sink to the 500-ft. level.—At a meeting of the directors of the New Monarch Mining Co. it was decided to purchase a new hoist and sink to the 1000-ft. level. A drift is being run from the Yak tunnel to drain the property.

OURAY COUNTY.

John Kelecher, operating the Neodesha mine under lease, shipped two cars of high-grade silver ore.—The ore recently opened on the 100-ft. level at the San Antonio mine, near Red mountain, assays from 50 to 100 oz. silver per ton with a fair copper content. John F. Roper is manager.—The plans for the smelter of the Mono-Baltic smelter, at Ironton, have been drawn and four carloads of machinery shipped to the property.

TELLER COUNTY.

A rich discovery was made at the Victor mine by the Roscoe Leasing Co. A raise from the old drift opened a shoot that assayed over \$40 per ton. Frank Roscoe is manager.—The old workings of the Damon mine, on Iron-clad hill, have been re-timbered and the lessees will commence shipping at an early date.—Lessees of the old dump at the El Paso reduction works are treating the accumulated tailing at an approximate profit of \$2 per ton.—The Portland Gold Mining Co., paid a dividend of 2c. per share on October 15, the total amounting to \$50,000. The mill buildings are being re-modeled and the company expects to have the new machinery running before the end of the year.—Lessees at the New Boston mine, on Womack hill, commenced shipping with a 25-ton lot consigned to one of the Cripple Creek plants.—Thirty tons of ore were shipped from the Prince Albert mine by M. Williams.—The Altman Leasing Co. has sunk the Pinto shaft on Bull hill to the 800-ft. level, and is cutting a station at that point. One of the conditions under which this company secured the lease on the property was that the shaft be sunk to this level before any lateral work was started. Edward Carpender, leasing on the surface of the property, has opened a shoot of rich smelting ore near the Ida Belle claim.—The raise at the Happy Year mine cut a vein that assays from \$60 to \$100 per ton. The company is shipping five cars of milling ore per week and will now commence shipping smelting ore. A. B. Whitmore is superintendent.—The September output of the Vindicator Consolidated Gold Mining Co. amounted to 3000 tons approximating \$90,000 in value.

IDAHO.

NEZ PERCE COUNTY.

A company headed by J. S. Irvin, of Ottawa, managing director of the International Portland Cement Co., and head of the Exshaw Portland Cement Co., of Alberta, has been organized to erect a cement plant near Orofino, where it has just acquired 223 acres of clay and lime beds, known as the J. M. Bartlett tract. The plant which will cover 12 acres, involves an initial expenditure of \$1,500,000, and will turn out 2500 barrels of cement per day. C. A. Reid, of Spokane, will be manager.

SHOSHONE COUNTY.

The Alice Mining Co. has started its mill between Wallace and Burke. There is sufficient ore blocked out in the mine to keep the 100-ton plant in operation at full capacity for several years. The company owns 24 claims which are being developed under the direction of James F. McCarthy, manager of the Hecla Mining Co. Though the property was located in early days the rich orebodies were opened only two years ago.—Maurice Blanchard, who has charge of the construction of the 25-ton smelter at Enaville, announces that the plant will be in operation early in November. It is designed to treat lead-silver ores, and cost approximately \$2000 to build. The furnace is of 90% silica brick designed to withstand a heat of 4000°.—Samples taken from the shoot recently cut at the Rainbow property, near Wallace, assayed 29% copper and 57 oz. silver per ton. The drift is now in 770 ft.—The Hamilton & Coeur d'Alene Mining Co. has been organized by Richard Dixon, manager for the Tarbox Mining Co., to open several claims adjacent to the Iron Mask mine, in Spring gulch. An 18-in. vein of galena has been found on the property.—The adit of the Gold Cliff Mining Co., near Murray, cut an 8-in. vein, samples from which assayed over \$20 per ton.—The Star Mining Co., operating between Wallace and Burke, is arranging to erect a concentrator at its property. The tax levied by Shoshone county on the valua-

tion and profits of producing mines in that part of the Coeur d'Alene district is 0.3c. on the dollar. The completed roll, prepared by the assessor, gives these statistics: The Bunker Hill & Sullivan, \$290,396.75 worth of property, including patented mining claims, machinery, and improvements, with net profits, \$901,701.50; the Coeur d'Alene Mining Co., \$28,415.50; the Federal Mining & Smelting Co., \$404,975.25 on its properties, and will pay taxes on net profits as follows: Mullan properties, \$16,855; Mace properties, \$693,124; and Wardner properties, \$221,609; the Helena-Frisco, \$25,867; Golden Chest, \$11,065; Gold Hunter, \$27,835; Hecla, assessed, \$72,708; taxed on net profits, \$108,798.81; Hercules, assessed, \$115,715; taxed on net profits, \$383,751.89; Pittsburg Lead, \$14,615; Snowstorm, assessed, \$60,565; taxed on net profits, \$162,148.56; Success, \$22,200. That the Idaho Northern Railway Co. is preparing to extend its line into the heart of the north side of the Coeur d'Alene is confirmed in an announcement by E. P. Spaulding, of Spokane, vice-president and general manager for the company. The permanent survey for the branch up the little North Fork has been approved, and it is given out that construction work on this extension will be commenced within a short time. This branch will afford quicker and more economical transportation to the mining districts and will tap a large timber belt.

MICHIGAN.

The excavating has been completed for the new engine and compressor house, and the concrete foundations for the new plant at the Hancock Consolidated finished. A new Sullivan 34 by 72 in. direct-connected Corliss hoisting engine, with a 15 by 15-ft. drum, hoisting an 8-ton skip 3500 ft. per minute from a depth of 4000 ft. will be installed. The compressor house will contain a 13-drill, a 16-drill, and a new tandem compound steam and air Corliss 20-drill compressor. The engine and compressor house will be of steel, fitted with a traveling crane. The boiler house will also be of steel, and will house two batteries of four boilers each. The smokestack will be built of reinforced concrete, by the Webber Chimney Co., of Chicago, and will have an inside diameter of 90 in., and be 130 ft. from the ground having a 12-ft. base.

NEVADA.

LINCOLN COUNTY.

(Special Correspondence).—The Prince Consolidated Mining Co., controlled by James L. Hackett and A. H. and E. L. Godbe, is shipping four cars per month from the Prince mine, at Pioche, which assays approximately 85 oz. silver, 32% lead, and \$6 gold per ton. The mine, which is opened by a 600-ft. shaft, has about two miles of development. Besides the ore of shipping grade, there are large reserves of milling ore, running 15 oz. silver and \$3 gold per ton, with 10% lead, 12% iron, and 56% silica. The silver occurs as chloride, the lead is a carbonate, and the iron an oxide and carbonate. Tests are being made at Salt Lake by the General Engineering Co. to determine the methods and equipment required for the new mill which is to be erected within the next few months. The plant will have a capacity of 100 tons per day, and be a combination of concentration and cyanidation. It will provide for wet-crushing, screen classification, jigging, and concentration on James tables, the table tailing to be re-ground in a tube-mill. All the wet-crushing, jigging, concentration, and re-grinding will be done in cyanide solution. It is assumed that most of the lead and some of the silver will be recovered by the jigs and tables. The re-ground product of the tube-mill is to pass to agitation and decantation tanks for further cyanidation to extract the silver and gold. The decanted gold and silver solution will then go to zinc boxes for precipitation. It is thought gasoline engines will serve for power, using distillate that costs in Pioche 17c. per gallon.—The Nevada-Utah Mines & Smelters Corporation, controlled by Hooley, Learnard & Co., of New York, owns the Raymond-Ely, Meadow Valley, Half Moon, Day, and Manhattan-Highland properties in the Pioche district. The Day is the most active of these. On it development to the amount of 1000 ft. per month is being made, consisting of drifts and cross-cuts from levels above the 900-ft. station.

The ore runs high in iron and manganese, has a limestone gangue, and only 1 or 2% silica, making a fluxing ore in demand at the smelting plants. Prior to the closing of the Tintic smelter 150 tons per day were shipped to that plant. The shippers obtained a freight rate of \$1.75 per ton on this fluxing ore from Pioche to Tintic, on ore that ran not over \$5 per ton in silver and lead; they were paid \$3.50 per ton for the iron and lime, which raised the grade to about \$9 per ton. An effort is now being made to make a satisfactory contract with other smelting companies. J. P. Gaskill, Western manager for the company, states that there are 10,000 tons of ore broken and ready to ship. The company usually employs a force of 75 men.

Pioche, October 16.

LYON COUNTY.

(Special Correspondence).—Llewellyn Humphreys, consulting engineer for the Mason Valley Mines Co., recently visited the company's mine at Yerington. He states that the branch railroad, under construction from Wabuska station to the Yerington district, will be ready to serve the Mason Valley mine by December. He says there is no doubt that a smelting plant will be erected in that district; and it is possible that parties interested in the Mason Valley, Nevada-Douglas, and other properties there may co-operate in building a plant to smelt their ores. The Mason Valley and Nevada-Douglas are well developed and both produce ore of smelting grade. The Bluestone also has a large tonnage of ore blocked out, but its ore is mostly of a grade that will require concentrating before smelting. Chas. A. Weck, manager of this property, has made many important tests in an experimental mill.

Yerington, October 16.

NEW MEXICO.

NAVAJO COUNTY.

A group of 16 business men from Prescott has filed on 1440 acres of coal land in the southern part of the county. A company will be formed to open the property, which is supposed to be an extension of the beds found near Gallup. Several previous attempts have been made to work the coal beds of this county, but the extreme distance from transportation made it unprofitable.

TEXAS.

BREWSTER COUNTY.

A company, headed by C. C. Lewis, of San Antonio, has made arrangements to operate the Brogas silver mine in the Davis mountains on a large scale.

EL PASO COUNTY.

(Special Correspondence).—F. W. Thomme, of Round Top, New Mexico, who owns the Sierra Blanca copper mine, in the Devil Ridge mountains near Sierra Blanca, is arranging to resume operations on the property. He expects to begin shipping ore soon.—The Black Kettle Copper Co., composed of Baltimore men, have started extensive development upon its mine, which is situated in the Quitman mountains south of Sierra Blanca. John N. Gilcrease, of Sierra Blanca, recently shipped his sixth car of copper ore from his mine in the Thunder Bird district, 75 miles east of El Paso. The ore is chalcopryite and the shipments so far have averaged 18% copper. The orebody occurs in crystalline limestone overlaid by granite porphyry, at the base of the Quitman mountains. At a recent meeting of the board of directors of the Republic Mining & Milling Co., held at Dallas, it was voted to resume development at the company's zinc mine in the Quitman mountains. The company has a mill and concentrating plant on the property which is called the Bonanza.

El Paso, October 15.

UTAH.

CARBON COUNTY.

The Utah Fuel Co. is beginning an 8300-ft. tunnel to be used as a conduit for a water supply for the town of Sunnyside. J. H. Winwood made the survey for the work.

PIUTE COUNTY.

(Special Correspondence).—The Sevier mine, which practically adjoins the Annie Laurie at Kimberly, is now the property of the Salt Lake Hardware Co., whose intention is

to open the mine to a greater depth, re-model the mill, and operate both next season. W. C. Marshall, of Salt Lake, the consulting engineer for the owners, states that there are seven veins on the property, and that two are on contacts of monzonite and andesite-breccia, two others in dacite, and the rest in andesite. The first two are 45 ft. apart, each having an east dip to a depth of 85 ft., where the dip changes to the west. It is on these that the greatest development has been done. The veins vary in width from 4 to 15 ft. The gangue consists of quartz, fluorspar, and calcite, carrying gold and silver from \$6 to \$8 per ton. The silver is in the ratio of 2 to 1 to the gold. It is partly free and partly associated with tellurium, occurring as calaverite and petzite. Some of the silver occurs as chloride and bromide. The intention is to equip the mill for cyaniding in agitation tanks, preceded by an acid treatment. The mine, which has 8000 ft. of development, has been opened to a depth of 300 ft. by adits. On the property is a steam-electric plant, but this will probably be supplanted by a hydro-electric plant on Clear creek, the work of installing which was partly done some time ago.

Kimberly, October 16.

SALT LAKE COUNTY.

(Special Correspondence).—The Wasatch-Utah Gold Mining Co. has over 12,000 ft. of development on its property at the mouth of Little Cottonwood canyon, the main openings consisting of a 315-ft. shaft and a 1400-ft. drain tunnel that connects with the shaft at the 270-ft. station. The property has a fissure vein in diorite, a high-grade streak of the ore assaying 6 to 10% copper, and 3 to 8 oz. gold per ton. This streak is 3 to 8 in. wide in a vein that contains large tonnage of highly silicious gold ore, some of which is being shipped to one of the Salt Lake smelters for use as converter lining. E. E. Price, formerly at the Yampa mine, is superintendent, and A. W. Nieman, of Chicago, manager. Sandy, on the San Pedro railroad, is the nearest shipping station.—The New England Gold & Copper Co., on Carr Fork, Bingham district, is shipping four cars per month of high-grade ore and concentrate, carrying gold, silver, lead, and copper, assaying \$30 to \$40 per ton. The property is in charge of D. J. Cook.—The Bingham & New Haven Mining Co. has its new mill in operation, handling 80 to 100 tons of ore per day. The ore is a sulphide of iron, copper, and lead, accompanied by some gold and silver; the gangue consists of silica and limestone. The mill is equipped with a Blake crusher, two sets of rolls, trommels, jigs, two pulsator jigs, Callow screens, and tanks; a Huntington mill for re-grinding the jig middlings; five Wilfley tables and three Diester slime tables. By a system of classifying and concentrating they obtain a lead and iron concentrate, an iron and copper product, a lead and iron middling. F. M. Wichman, mill superintendent, states that the ratio of concentration is 3 to 1. H. J. Turley is general superintendent.—The Utah-Apex mill has been re-modeled and is ready to operate on a lead-silver ore. William Carkeek has charge of the mill.

Salt Lake, October 18.

TOOELE COUNTY.

(Special Correspondence).—Development of the Western Utah Copper Co.'s properties, in the Deep Creek district, during the last six months, has resulted in opening 100,000 tons of copper ore claimed to assay 5%. It resulted, also, in opening a body of lead-carbonate ore 70 ft. wide that is said to assay 5 to 45% lead, and 5 to 45 oz. silver per ton. This body has been opened to a depth of 300 ft. No shipments will be made till closer railroad connections are made as the hauling to the nearest station on the Western Pacific road is too far to admit of profitable shipping. This is one of the properties of which Duncan McVichie, of Salt Lake, is manager. Mr. Humes is in direct charge.—E. S. Leaver, former manager of the Goldfield Reduction Co.'s mill, at Goldfield, has taken a lease on the Daisy mine and mill, on the West Dip, in the Mercur district. The property has been idle several years, and Mr. Leaver will re-open the mine and repair the mill. He will add to it such equipment as is necessary to cyanide the slime separately from the sand.

Mercur, October 16.

WASHINGTON.

CHELAN COUNTY.

The Supreme Court of Washington has handed down a decision that J. H. Holden is the owner of the entire Holden mine, in the Lake Chelan country, and that he is entitled to the entire proceeds from the sale of the property to Jay P. Graves, of Spokane, and his associates. The decision means \$500,000 to Holden and a corresponding loss to W. S. Denny, of Seattle, who sued for a half interest in the property. Holden and Denny were formerly the closest of friends. They were on a hunting trip together in the district 11 years ago, and Denny turned over his share of the provisions to Holden to go on a prospecting trip. The result of that journey and grubstake was the discovery of the famous Holden copper mines. It was a hard property to develop, and finally Holden gave an option to the Graves interests whereby the latter assumed control of the property. Denny filed suit for his interest in the mine a year ago, and the Supreme Court ruled that a man who waited ten years to assert his interest, can hold no valid interest in the property.

FERRY COUNTY.

(Special Correspondence).—Two months have been devoted to mapping and making a petrographical study covering 56 sq. mi. of the Republic mining district by the Washington State and United States Geological Surveys. A report on the mineral resources of the district will be published. Waldemar Lindgren, of the United States Geological Survey, supervised the field work the last three weeks.—The lessees of

Map of Washington.

the Ben Hur mine are employing nine men, stopping ore on the 125-ft. level, and are unwatering the shaft to resume work on the 250-ft. level. The leasing company is operating three machine-drills and shipping about 100 tons of ore per week, which assays from \$10 to \$30 per ton. Large quantities of low-grade ore are being mixed with high-grade material, to make a fair average for shipment. A new ore-shoot, 4 ft. wide that assays \$45 per ton has just been opened.—Ore is being stoped above the intermediate level of the Black Tail mine. Five carloads were shipped during the past month, and two more are ready to ship. This property has recently been purchased by Spokane people, with F. E. Pritchard, of Rosalia, the main stockholder.—The Flag Hill mine is again in operation, after several years of idleness, having passed into the hands of the Flag Hill Mining Co. John Gatenbein, of Republic, is manager. A 12-in. vein is being opened which assays from \$50 to \$100 per ton. Three veins have been prospected on the Flag Hill by open-cuts, adits, and shafts.—The Midget mine, formerly known as the Tom Thumb, has been leased by the New Republic Co. for three years. It was opened by the Tom Thumb Gold Mining Co. to a depth of 400 ft. and is fully equipped with a steam boiler and hoisting engine; a Leyner air-compressor and drills, and electrical machinery for lighting the mine. The property has been opened by drifts on three levels and a cross-cut to the vein on the fourth. The former management estimated about 10,000 tons of \$9 ore is blocked out in the mine. A carload was shipped several years ago, which assayed \$23 per

ton. A spur of the Great Northern railway was built to the mine at that time.—The Oversight Mining & Milling Co. has installed a new hoisting engine at the No. 36 shaft to sink on the iron sulphide vein discovered last fall. The shaft is down 43 ft. in ore.—The Southern Republic Co. has unwatered the Princess Maud shaft below the 500, and, as soon as the mine is thoroughly drained, will resume work on the 600-ft. level.

Republic, October 18.

OKANOGAN COUNTY.

(Special Correspondence).—Negotiations are pending at Camp Hilbert, near Ruby, with an English syndicate for 120 mining claims, including the Index, Crescent, and Wolverton. Fred A. Bell, a broker of New York City, is financing the deal, and a holding company will be organized with a capitalization of \$25,000,000.—The old Ruby camp is having a revival of mining activity, after a dull period extending over several years. One of the indications is the installation of machinery by the Mine Operating Co.—The German-American Mining & Milling Co., owning seven claims south of Oroville, will begin development immediately. The claims are on a contact vein from 40 to 100 ft. wide, and contain gold, silver, copper, and lead, in quartz gangue.—The Golden Chariot Mining Co., owning four claims on Goat mountain, five miles northwest of Oroville, is sinking a shaft, now down 240 ft., on a contact vein, with ore assaying from \$17 to \$63 per ton in gold, silver, and copper.

Oroville, October 15.

STEVENS COUNTY.

(Special Correspondence).—The Factor Mining Co. is organizing to develop the Factor group of claims, on First Thought hill, near Orient. At a depth of 10 ft. an ore-shoot was cut that assayed \$17.50 per ton.—The Liberty Copper Mining Co., operating near Chewelah, has ordered an air-compressor, power-drills, steam hoist, and 100-hp. boiler. A large vein of copper ore has been opened on the adit level. A shaft will be sunk, and new levels driven. The company expects to ship ore as soon as the machinery is installed.—The Lehigh Cement Co. is to build a plant at the junction of the Pend d'Oreille river and Sullivan creek, near Metaline, which will be operated by a 10,000-hp. hydro-electric plant to be erected on Sullivan creek by the Sylvester Engineering Co.—The Deer Park Mining Co. has about completed the construction of its concentrating plant and will start it up in a few days. The water will be taken from a creek about 200 yards distant and the company will commence shipping concentrate in the early part of December.

Deer Park, October 18.

CANADA.

BRITISH COLUMBIA.

(Special Correspondence).—In the Le Roi mine at Rossland one of the diamond-drills on the 1600-ft. level has cut a 4-ft. body of rich ore.—For the month of August the Le Roi No. 2, Ltd., shipped 3010 tons of ore, averaging \$23 per ton, and is now shipping 450 tons per week. A station has been cut in the new shaft at the 1000-ft. level.—The new compressor at the Inland Empire has been started.—At the Athabasca mine, near Nelson, where development has been carried on actively for some time past, a large body of rich ore has been uncovered.—Two gold bars, weighing together about 40 lb., were shipped from the Nugget during the past week. This shipment of bullion, valued at about \$8000, represent a four weeks run at the mill. There is a little work going on in Poplar Creek district all the time, although the boom has dropped. E. Mobbs has sent a 3-ton shipment to Trail smelter from the claim he is operating, and it is claimed that if it runs \$4 per ton gold it will pay to operate. Ten men are employed at the Society Girl mine, at Moyle. Some ore has been found in the upper workings assaying 67 oz. silver, 7% copper, and 58% lead. It is expected to cut this orebody in No. 2 adit now in 850 ft.—The incline on No. 5 seam at the Hosmer mine, at Hosmer, has been started. This company owns five miles of rich coal land adjoining the Crows Nest Pass Coal Co. holdings. It is a subsidiary company of the Canadian Pa-

cific Railway Co., which uses most of the output.—In the work and shipments of the mines near Phoenix during the past week interest attaches to the increased shipments of the Oro Denoro and Mother Lode properties of the B. C. Copper Co. to the Greenwood smelter. The Oro Denoro increase was 900 tons and the Mother Lode about 500 tons over the previous week. Since P. S. Couldrey, lately with the Le Roi No. 2, Ltd., took over the superintendence of the B. C. Copper mines, the output has been steadily increased.—Granby shipments dropped about 900 tons during the last week, owing to the breaking down of one of the big crushers at No. 2 outlet. For the year ending June 30 last the actual cost of making and marketing copper at the Granby was 10c. which was 24c. lower than for the preceding fiscal year. It is anticipated that with the improvements added this year this cost will be reduced to 9c. per lb. The surplus on above date was \$2,698,687, which is \$243,507 greater than for the previous year. Cash and copper figure \$600,459, about \$178,834 more than for the prior year.—On the Vernon claim, Camp McKinney, a 4-ft. vein of galena ore has been opened. The Bruce mine at Midway is in financial trouble and some of the miners have not received their wages. J. Cleveland Haas, of Spokane, the consulting engineer, states that the company's debts will be paid.

Rossland, October 15.

MEXICO.

CHIHUAHUA.

The properties of the El Porvenir Mining Co., near Parral, have been taken over by the Compañía Minera La Corona and a small mill will be erected on the ground. The latter company will issue bonds to raise money necessary for the construction work.—The Ricamole Mining Co. is to resume operations at its property northeast of Parral.

DURANGO.

The Boca del Cobre Mining Co. has opened a body of high-grade copper-silver ore on the sixth level of the El Rosario mine, and is sinking to the seventh. The average assay of the ore shipped from the fourth and fifth levels was 7½% copper and 100 oz. silver per ton.

JALISCO.

The State Government has just granted a concession to James H. McCreery and Richard Ivey to construct an electric railroad from Magdalena, the present terminus of the

Amparo Mill.

Southern Pacific, through Hostotipaquillo to the Santiago river at a point near the Cabrera mine of the Virginia & Mexico Mine & Smelter Corporation.

OAXACA.

The largest denouncement ever made in this State has recently been published by the local land office. The property which consists of 61 claims is called La Escuadra and was located by Fred Woolrich.—F. D. DeVote, of the Rio Seco Mining Co., has taken six pertenencias in the Etla district. The property has been named Pelado Grande and the minerals present are gold and silver.

SONORA.

A 2500-ton lot of rich copper and silver matte was sent to the 4-C smelter at Cananea from the El Triunfo mine. This is the second shipment from this property.—The Badger Mining Co. has commenced work on its property in the Arizpe district. C. H. Waters is manager.

NEW YORK.

Copper Surplus and Sales.—Davis-Daly Contest.—La Rose and Nipissing. — Kerr Lake to Pay Large Dividend. — Ely-Central. — Camp Bird.

The interest in copper circles was this week centered largely in the forthcoming figures of the Copper Producers Association. The accumulated copper surplus is and has been for some time the chief obstacle to higher prices. Buyers have seen no reason for committing themselves for future consumption so long as the market has failed to show any material gain in absorption. The September statement of the Association was made public the first of this week. Its showing had been pretty well discounted. It was expected that there would appear an increase in accumulated surplus of about fifteen million pounds of copper. The exact figures given out are 15,840,207 lb. Added to the accumulated surplus for the eight months preceding, the total surplus on October 1 is estimated at 151,472,772 lb. Of this gross figure, 122,357,260 lb. was on hand January 1, 1909, so that the real increase for the year up to October 1 is 29,115,512 lb. This accumulation is not at all alarming when the fact that many producers have been added is considered, and the further fact that the country has been slowly recovering from a depression which brought to a standstill many industries, such as the building of inter-urban trolley lines and the installation of new telephone plants, which in normal times are among the heaviest users of copper. It is not the weight of the copper surplus in and of itself that makes it at all a grave feature, but the fact that until it begins to melt it will be difficult to bring buyers into the market for anything beyond immediate needs.

Deliveries of copper during September totaled 102,182,932 lb., which, as was the case in August, was divided almost equally between domestic consumption and delivery for export. The Association estimates the foreign visible supply of copper at 197,608,320 lb., giving the world's present accumulation a total figure of 349,081,092 lb. One of the members of the Association states that an effort is being made to get the chief interests abroad to join in an organization similar to that of the Copper Producers' Association in order to have available figures which will adequately cover the output of the entire world.

The contest which has been waged in Davis-Daly is evidently at an end. The annual meeting has been adjourned to October 15, and no further court proceedings are expected. F. A. Heinze appears to have the support of all but the Boston stockholders, and these are now to have two members on the board of directors.

The open market has exhibited several interesting features during the week. The advance in Tuolumne, an upward spurt in Ely Central, and a vicious raid by the bears upon La Rose and Nipissing being the chief incidents. There has been no explanation as to what brought about the sudden drop in La Rose. The property now stands at the head of the list of shippers at Cobalt; it is reported to have in its treasury a surplus which would admit payment of the present dividend of 16% for a year if no further ore was produced; the development of the Lawson property recently acquired is just well under way, and it is expected that this ground will prove to be quite the richest yet explored in the camp. Notwithstanding this situation a strong drive was made at both La Rose and Nipissing on Friday, and the former was sold off from 7½ to 5¼, the latter from 11% to 9%. Apparently the break was caused by the liquidation of some large holder, either forced to sell or who threw his holdings on the market because dissatisfied with the consolidation plans. Not all of the interest in the Cobalt market was centered in Nipissing and La Rose. It is semi-officially announced that Kerr Lake expects to take the place at the head of the column of dividend payers with a declaration of 31¼%, which will amount to \$1.60 per share.

Ely Central is being made the medium for a big advertising campaign and the market has been hoisted to 2¼ per share. The enthusiasm which the public has developed for the low-grade milling or 'porphyry' coppers seems to prevent analysis of conditions, as is necessary in estimating the value of copper properties which at the best are five years from the point where a pound of copper could be produced at a profit, and to which in other cases still graver objections may be urged.

Among the London mining stocks active in New York, Camp Bird continues to hold attention. On the strength of the option obtained by the Camp Bird, Ltd., upon the Santa Gertrudis the London market has been an active buyer, and much higher prices seem to be anticipated both here and on the other side.

WASHINGTON.

Report of Land Office.—Unrecorded Titles —Changes in Regulations.

The annual report of Fred Dennett, Commissioner of the General Land Office, has just been made. The report shows that the total area of land entered during the year amounted to 19,090,356 acres, a decrease of 1,907,209, as compared with 1907. The total area upon which final proof was made is 8,068,044.85 acres. The public lands remaining amount to 754,895,296 acres. The total cash receipts from the sales of public lands were \$11,492,453. Mr. Dennett makes a number of recommendations. He asks that legislation be enacted that will permit of all lands which are to be brought under an irrigation project being withdrawn from entry at the time of the announcement of the enterprise. Under the present law, the lands are open to homestead entry immediately upon the declaration of the project. A law specifically providing for the punishment of persons who fraudulently obtain or attempt to obtain title to public lands is asked. Heretofore such offenses have been prosecuted under the statute punishing conspiracy to defraud the Government, and under the laws prescribing penalties for perjury and subornation of perjury. The Commissioner makes the statement that the appropriation made by Congress for the transcribing of the field notes and tract books destroyed in the San Francisco fire lapsed on December 31 last, and that no provision has since been made for the copying the plats of mineral surveys, so that the Surveyor-General has to make exhaustive researches in the field notes for the purpose of ascertaining conflicts in proposed mineral surveys. This necessitates great additional labor and cost. The Commissioner asks for an appropriation of \$8000 to carry on this work. There are now in the general and local land offices some 400,000 patents to land which it has not been possible to deliver to entrymen. In these cases the successful applicant has been satisfied to record the receivers' receipt and has then, for some reason, ceased to call for mail at his last known address. The Commissioner declares that some step should be taken to have these muniments of title properly recorded. In many instances the patents are for lands in States in which all the public lands have been exhausted for a number of years, such as Indiana, Ohio, and Illinois.

The following changes in the regulations are promulgated by the Commissioner: Settlers, residents, and individual miners and prospectors in Alaska are permitted to take, free of charge, and without previous permit, timber not exceeding \$50 in value in any one year for their actual use for domestic purposes. Timber is disposed of in larger quantities to the persons named and to residents and those doing business in Alaska upon application to the receiver of the proper land office, and after appraisal by a special agent and deposit of the appraised value, cutting is permitted to begin; subject, however, to stoppage of the cutting in event of non-compliance with the terms of sale. Declaratory statements and entries are not received upon coal land withdrawn for classification, but those who have opened and improved coal mines during the period of withdrawal are permitted to file in the proper land office a notice of claim, and upon classification of the land, are permitted to assert their formal claim to purchase at such price and upon such terms and conditions as are in force at time of the restoration of

the lands. Affidavits in coal land cases may be made before the register or receiver, or any officer authorized to administer oaths, in the land district where the lands are situated. Abstracts of title, prepared by duly authorized abstractors, are received as evidence of title to mining claims and of water rights when the abstractors have furnished copy of existing local statutes by which they are authorized to compile abstracts, and certificates by the proper local officials that they have complied with such statute. Similar evidence of water rights in desert land cases is received upon like showing.

The United States Geological Survey has just published, as Bulletin 395, a report under the title, 'Radio-activity of the Thermal Waters of Yellowstone National Park', by Herman Schlundt and Richard B. Moore, giving the results of recent tests. Typical spring waters from all the principal basins of thermal activity were tested, and wherever gases were evolved from a spring these also were tested for their radio-active properties. Many solids, consisting of spring deposits, water residues, and rock samples, were examined quantitatively for the radium content. The determinations were all made by the electrical method. The results show that the underlying rock in the park contains radium and in some localities thorium in sufficient quantities to make the waters and gases decidedly radio-active. No tests were made to determine the presence of helium, which is a constituent of the gas escaping from several of the more active European springs.

LONDON.

Zinc.—North Broken Hill and Broken Hill South Silver, Reports.

The various mines at Broken Hill have received considerable attention in London lately, partly owing to the success of the zinc tailing plant at the Zinc Corporation and the great activity of the De Bavay's Treatment Co., both of which ventures promise to place Broken Hill in a strong position in the zinc market. But apart from the zinc question the mines have received a much closer study since the announcement of the approaching exhaustion of the Proprietary company's deposit. Two of the most promising companies on the range have issued their reports this week, and as they have been closely scanned here, it is appropriate to give some account of them. These companies are the North Broken Hill and the Broken Hill South Silver. They are situated at opposite ends of the range, and both have done exceedingly well recently in spite of the low prices of lead and silver, which have been sufficient to suspend the profits of some of their neighbors.

According to the report of the North Broken Hill for the half year ended June 30, 66,797 tons of ore was treated, averaging 15.9% lead, 7 oz. silver, and 14.3% zinc. The yield of lead concentrate was 11,372 tons, assaying 70.87% lead, 21.83 oz. silver, and 6.61% zinc. The recovery was 75.38% of the lead and 53.63 of the silver. In addition 33,842 tons of zinc tailing averaging 19.9% zinc, 3.9 oz. silver, and 4.2% lead was produced, together with some slime and barren tailing. The whole of the zinc tailing has been delivered to the De Bavay's Treatment Co. A new mill is in course of erection and will be completed toward the close of the year. This mill will treat 5000 tons of crude ore per week and the output will therefore be greatly increased. With regard to the ore reserves no definite figures are given, but the mine is opening up well at all levels as far as has yet been sunk, namely 1130 ft. The whole of the output of lead concentrate has been sold up to the end of 1914. The working costs during the half year in question were: mining 9s. 11½d. per ton, milling 3s. 6¾d., development 1s. 7½d., or a total of 15s. 1¾d. per ton. The profit and loss account shows receipts of £82,765 from lead concentrate and zinc tailing, working expenses £51,559, administration and taxes £2717, dividend £14,000 (at the rate of 20% per annum on the capital of £140,000), and capital written off £13,095.

The Broken Hill South Silver M. Co. reports that during the half year, January to June, the amount of ore raised was the greatest of any half yearly output during the 16 years history of the mine, namely 137,848 tons, as compared

with 112,288 during the previous half year. The assay value of the ore raised was 14.9% lead, 12.1% zinc, and 5½ oz. silver. From this ore was produced 20,746 tons of lead concentrate assaying 73.6% lead, 4½% zinc, and 19.3 oz. silver; 41,563 tons of zinc tailing assaying 4% lead, 18.7% zinc, and 3.4 oz. silver; 58,368 tons of second-grade tailing assaying 2½% lead, 10% zinc, and 2 oz. silver; and 17,162 tons of slime assaying 12.7% lead, 12% zinc, and 5.7 oz. silver. Owing to the limited demand for lead in the early part of 1909, the concentrating mill did not run at its full capacity, but toward June the output was raised to over 1000 tons per week. The whole output of lead concentrate for the remainder of 1909 has already been sold and negotiations are practically concluded for the disposal of the product for a number of years. As regards the disposal of the zinc tailing, some of this material is already being sold to the Zinc Corporation. Recently additional contracts were made with the De Bavay's Treatment Co. whereby some of the tailing will be supplied at 3s. 9d. per ton to be treated by the present plant, and a further supply treated by the new plant for a period of seven years. The price to be paid for the latter is 3s. 6d. per ton on delivery, and after another 3s. 6d. has been credited to the De Bavay Co., the remaining profit is to be divided equally between the two companies. In spite of adverse circumstances ruling at Broken Hill, the working costs have been still further lowered. Mining costs were 9s. 2½d. per ton, development 9d., and concentration 3s. 11d. The income from the sale of lead concentrates was £155,922, and receipts from the Zinc Corporation £4032, making a total of £159,954. The mine costs totalled £109,441, leaving £50,513 to go to profit and loss account. General administration, office expenses, and taxes absorbed £3900, and £10,742 has been written off for depreciation. Dividends amounting to £40,000 were distributed, which is at the rate of 48% per annum on the paid-up capital of £163,508. The ore reserves are estimated at 3¼ million tons above the 970-ft. level, which level continues to open up in a satisfactory manner. In addition the company has 1¼ million tons of zinc tailing and slime stacked on the surface.

GOLDFIELD, NEVADA.

Mill Additions.—Clermont Ore-Shoot.—Florence Mill.—Daisy Stops Company Work.—Nancy Donaldson.—Combination Fraction.

Official announcement has been made that the first step in increasing the capacity of the Consolidated mill will be the placing of six 6-ft. Chilean mills in the present structure. It is planned to have these in operation within 90 days. The mills, together with the necessary tanks, tables, etc., will be purchased from various manufacturers and in-

General View of Goldfield.

stalled by the company. This additional machinery will increase the capacity of the plant to nearly if not quite 800 tons daily. The increased capacity will result from the ability to feed a greater tonnage to the stamps as the Chileans will relieve the tube-mills. It is computed that fully 75% of the ore now being put through the latter will go directly to the tables from the Chilean mills. The work of clearing away the remaining portions of the wrecked Combination mill is going forward. The lower workings are being cleaned up and supports installed. Production will be from the caved area on the fourth and fifth levels and

by far the greater part of the caved material will be treated in the mill. A large crusher will be installed between the apex of the Combination vein and the railroad and from it a belt-conveyor will carry the ore to the company's steel hopper-bottom cars. Stopping is now in progress on this vein at the southern end of the Combination No. 1, and on the Combination No. 2, where ore of excellent grade is being taken out for a width of 20 ft. in places at the fourth level, and the ground is being explored at the fifth level. The cross-cut from the Combination Fraction at the 600-ft. level is being driven across the Combination No. 1 toward the old workings of the January mine.

Development on the three lower levels of the Clermont continues to yield gratifying results and preparations are being made to begin stopping in the rich orebody opened at the 730-ft. level. A raise is being driven to the 600-ft. cross-cut from the Mohawk. The work continues to expose high-grade ore in large quantity and the company's revenue can easily be increased at any time. After passing through 27 ft. of high-grade ore at the 730-ft. level, lower grade material was found, and further cross-cutting has been suspended. The ore-shoot, known as the Mohawk-Jumbo or Macmillan ore-shoot, has now been opened at the 260, 600, 730 and 860-ft. levels, and miners employed in the Clermont declare that the 1000-ft. level is about to enter the same vein. At every point where the shoot has been penetrated it is shown to be of great value and of large size. The ore-shoot at the 860-ft. level is only less rich than at the 730-ft. level. The vein was penetrated for a distance of 8 ft., and the face sampled from \$300 to \$1000. Drifts are being driven both ways along the hanging wall, but both at this depth and above the ore apparently improves in quality as the foot-wall is approached. A peculiarity of this ore-shoot lies in the fact that at the deeper levels the ore responds more readily to treatment by milling than that found nearer the surface. At this depth the ore occurs in latite, a formation which was formerly believed to be barren and which underlies the dacite that was supposed by many to be necessary to deposits of gold ore in this part of the district. The latite appears also in the Florence and Combination Fraction and as far south in the district as the C. O. D.

The Florence mill is now operating at nearly its full capacity of 160 tons daily with the newly installed machinery running smoothly. The assurance is given that there will be a large and steady output of bullion. Experiments are being conducted with a view to installing a chemical plant by means of which the concentrate will be treated in a manner similar to that employed by the Consolidated. A spur track has been built from the line of the Tonopah & Tidewater railway. The system of development instituted by the new superintendent, Willis Lawrence, has opened additional reserves of both high-grade and milling ore, and a shoot opened on the sixth level in the Engineers' vein, has exposed a wide seam of rich ore carrying free gold in quantity and accompanied by 4 ft. of excellent milling ore. For its entire width this ore is worth fully \$200 per ton.

Operations on company account will probably be suspended indefinitely on the Daisy unless results show material improvement before the expiration of this month. The high cost of marketing the product, together with the fact that, owing to the character of the ore, it must be sent to the smelters, has rendered it impossible to make a profit from any save the richest ore found in the mine, and although the company for seven months succeeded in making a small profit above its operating expenses, it has been decided to suspend company work. There are six leases now on the Daisy, and at three points high-grade ore has been exposed and shipments made. Lessees working from the No. 2 Company shaft have opened a strong vein and have begun shipping as have the Golden Daisy and the Millard-Jones leases, and it is reported that the Toplitz lease will resume operations shortly. From a point near the end of the company tunnel on the Columbia Mountain mine, lessee Thomas will drive to the vein which has been opened at a depth of 110 ft., and will raise to connect with his shaft. The vein is of excellent character, lying between granite and porphyry, a condition unique in the Goldfield

district. Samples of the ore have yielded as high as \$2000 per ton.

The Nancy Donaldson shaft is down 135 ft., and besides opening seams of high-grade ore near the surface, has passed through a large body of low-grade ore and the management is greatly encouraged with the showing. This prospect is situated nearly nine miles east of the town of Goldfield and on the Red Mountain mineral belt. Good ore has been opened at a depth of 400 ft. in the Diadem lease on the east end of the Great Bend. On the Merger Mines Co.'s claims high-grade ore has been exposed in seams and a number of shipments made from time to time. The Combined Mining & Leasing Co. will soon resume driving for the junction of two of the best veins in this part of the district, and from which high-grade has been mined near the surface.

Combination Fraction has been one of the chief centres of interest of late owing to the discovery of a large and rich orebody and the declaration of a dividend. Despite the small area, about eight acres, the mine has been a favorite, and most flattering predictions regarding its future have been made because of its situation. On all sides of the Fraction are claims that have been highly productive, including the Mohawk, Combination, and Jumbo of the Consolidated, and the Florence and Cornishman claims of the Florence. High-grade ore was mined at two levels on the Mohawk up to the boundary line of the Fraction though these ore-shoots have not produced rich ore on the latter. Recently the output of the Fraction has been around \$50,000 monthly, and is expected to exceed this amount. The increase in the mill-heads have been raised from \$25 to \$40 per ton since mining on the new vein began. George Wingfield personally controls the Fraction, which, by the terms of an agreement entered into over two years ago with the Consolidated, is forever immune from litigation arising from apex disputes.

SALT LAKE, UTAH.

**Ohio Copper Mill —Salt Lake Men in Ely —Deeper Mining for Tintic.
—Ajax Sold to Loose and Associates.—Daly-Judge Gets More Ore.**

Colin McIntosh, general manager of the Ohio Copper, says that three of the seven sections of the steel trestle work are completed, and that the entire work should be finished within the next 30 days. Lack of experienced erecting men has delayed the work. Two units of the reduction plant are ready, and the contractors are now at work on the third section of the mill. The first unit will be commissioned immediately upon the completion of the trestle, which connects the Mascot tunnel with the mill. The management expects to have the entire mill in operation within a few months time, and while the capacity is nominally only 2250 tons, Mr. McIntosh expects to treat 3000 tons and make more than an 80% saving. The plant includes both Chilean mills and stamps.

Salt Lake mining men control some of the smaller properties in Ely. Among these are the McDonald-Ely, Federal Ely, Ely Witch, and a number of other properties in the low-grade porphyry belt. Recently there has been considerable activity in these stocks, and it has leaked out that Cole-Ryan interests are after more territory in that section. Some of the largest owners in these properties have acknowledged that they have been approached, and one of the largest individual shareholders in McDonald-Ely has been offered a price equivalent to 100% profit on his original investment. Development in this ground has shown some large deposits of ore assaying more than 2% in copper. Salt Lake mining men are inclined to add to their holdings in the Ely district, rather than sell. D. C. Jackling is reported to be seeking a footing in Ely. As both Cole-Ryan and the Jackling forces are reported to be actively engaged in buying Ely territory, it will mean sharp competition. A formidable rival for the Nevada Consolidated, Cumberland-Ely, and Giroux companies seems likely.

Deeper mining is being carried on in the Tintic district. The Knights have sent the main shaft of the Iron Blossom down 11,000 ft. Drifts from the lower levels has opened some large deposits of lead carbonate. J. Will Knight has

been appointed general superintendent. The Colorado workings are to be extended downward 1000 ft. or more, and it is expected that this, with the deep workings in the Beck Tunnel ground, will result in discovery of the orebodies believed to exist in the Crown Point territory, another Knight property. The May Day in Tintic has reached a depth of 1100 ft., and driving is now progressing from this level toward the ore that was uncovered 100 ft. above. Sioux Consolidated is to be developed to a greater depth. Colorado and Sioux are doing well, as evinced by the posting of the regular dividends of 8 and 7c. respectively last week. The Uncle Sam Consolidated made its regular distribution of 8c. The closing of the Tintic smelter put the Iron Blossom out of the dividend list for September, the company being unable to get returns from the United States company in time.

The Ajax Mining Co. has passed into the hands of C. E. Loose and associates, of the Grand Central, Carisa, Victor, and other big mining properties of the Tintic district. The Ajax property has been under the management of Thomas Weir for more than ten years. It was a great producer in the early days and paid dividends amounting to \$1,000,000. Its workings have attained a depth of 1100 ft., but the ore in the lower workings was of too low a grade for profitable handling. Mr. Loose and his associates own some adjoining ground, known as the Golden Chain and Cleveland groups. They have quietly gathered up the controlling interest in Ajax stock, and now propose to consolidate with the ad-

ment for the reason that some litigation has been going on for a year past as to the title of two of its ore-bearing groups. Of recent date this company has opened a deposit on the 1300-ft. level on which they have raised 140 ft., and the extent of the ore has not been determined. It is a sand-carbonate which can be literally shoveled out, without the aid of blasting and requiring very little effort to break down with picks. It is similar in character to the rich ores that have been found on the 700 and 1100-ft. levels, from which the management has been able to mine a large portion of the immense dividend that has been paid by this company during the last 20 years. One of the consulting engineers of the company is authority for the statement that this late development will be the means of doubling the value of the property, which has been the greatest silver-lead producer in Utah for ten years.

BUTTE, MONTANA.

Colorado Mine Reduces Force.—Criticism of Management. — American Metal Co. and Zinc Deposits.

A number of men have been laid off at the Colorado mine by the Davis-Daly Copper Co. It has been stated in Butte that the reduction of the force in no way lessened activity in development or mining, but that it was in the interest of economy. A man closely associated with the company made the statement that economy was necessary, as he understood that the treasury was practically empty. He declares that a most expensive policy has been pursued and that mining has been done at a great loss to the company for no other purpose than to be able to say to the public that the company is "shipping ore" and is in a "producing stage." "Splendid results have followed the development at the Colorado, and I believe a big mine will be opened there," said the Davis-Daly stockholder referred to above, "but it is an absurd and dishonest policy to mine and ship ore while development is going on and the mine is not sufficiently opened. The ore shipped is of a low grade, the average being little above 3% copper. The best interests of the company have been sacrificed in order to advance personal interests." While there has been a great deal of criticism of the Heinze management on the part of stockholders in Butte, with only a few exceptions the Butte shareholders sent their proxies to Mr. Heinze to be used by him at the annual meeting.

In the opinion of men familiar with developments in the Colorado mine, that property is certain to become a big and important producer. The company is accomplishing some record work in development. It is expected that the big vein will be reached by the cross-cut on the 1500-ft. level within the coming week. The Colorado is the only property of the Davis-Daly company on which any work is being done.

The advent of the American Metal Co. into the Butte district has attracted attention to the large zinc-ore deposits in Butte mines. An old report on the Emma mine, formerly owned by the Butte Mining & Development Co., now the property of the Butte Copper & Zinc Co., shows that between the 400 and 800-ft. levels there is an orebody 130 ft. wide, the largest in the Butte district, and that the assays taken in 1903 gave from 16 to 32% zinc, with a high percentage of lead, some gold and silver, and a fraction of 1% copper. The property has been closed and the surface plant dismantled ever since the failure of the Butte Mining & Development Co., which forfeited its option on the property. The Butte Zinc Co. later acquired the Emma, but has never done anything with it. The Sieligmans and others of New York are interested in the Butte Copper & Zinc Company.

The American Metal Co. is making preparations for the erection of the zinc concentrator for the Butte & Superior Co. It is now stated that the plant will have a preliminary capacity of 500 tons per day. The contract between the American Metal Co. and the Butte & Superior provides that the former will advance \$250,000 to the mining company, \$150,000 of it to be used in building the concentrating plant and \$100,000 to be added to the treasury of the mining company and to be used for development. The Metal company contracts to purchase the product of the concentrator for a

Eastern Nevada and Western Utah.

joining properties and work through the deep shaft of the Ajax property. The surface workings of the Golden Chain and Cleveland show some first-class deposits of silver-lead and copper ore, and with greater depth they expect to get a producer of considerable magnitude. It is understood that the general offices of the new company will be removed from Salt Lake to Provo.

Daly-Judge is adding new laurels to the recent ore deposits tapped at a depth of 1400 ft. In the Daly stope they have just cut some water courses that are producing a good tonnage of first-class lead ore. The flow is being handled through the drain tunnel at the 1200-ft. level. George W. Lambourne, general manager, says that they will not attempt to make a heavy extraction until they have completed the tunnel, which is being driven from the Snake creek side of the range. This will drain the property below the 1800-ft. level, and then both the first and second-class product can be mined economically. The Daly-Judge has one of the largest mineral-bearing estates in Park City. Since operations were first begun the management has been much troubled with water. The new tunnel will drain a large area on what is known as the Bonanza Flat country, and a number of companies have signified their intention of beginning operations.

New orebodies developed in the Silver King Coalition Mines ground, at Park City, is of frequent occurrence. The owners are not inclined to give out an account of develop-

period not less than five years, the price to be paid being governed by the price of zinc and the quality of the concentrate. It is understood that the Butte & Superior will receive about \$3 net per ton for its ore, and there are now no less than 1,000,000 tons blocked out in the Blackrock mine.

DENVER, COLORADO.

A. I. M. E. at Leadville, Pueblo, and Colorado Springs.

The members of the American Institute of Mining Engineers who have been in the West, spent October 10 and 11 in Colorado. After a brief stay at Glenwood Springs their train was taken to Leadville, where a number of members of the party visited the Yak tunnel and mill. From Leadville the party went to Pueblo, where the men spent the day, while the women went on to Colorado Springs and Manitou.

At Pueblo the Denver & Rio Grande furnished a special car and detailed an engine to serve the party. In this way no time was lost in traveling from one plant to another, nor in getting refreshments, which were served on the train. The first plant visited was the Minnequa plant of the Colorado Fuel & Iron Co. Here the iron was traced from the ore-bin through the plant to its final form in finished rails. The physical test of dropping a 2000-lb. weight on a 5-ft. section of the rail from a height of 20 ft. was very instructive to the travelers. The plant of the United States Zinc Co. was next on the list. Here the party saw the magnetic separation of zinc blende from iron sulphide. The revolving water-jacketed cooler in which the ore is chilled after a light roast came in for a large share of the attention. At the copper-lead smelter of the American Smelting & Refining Co., the party was shown the modern pot-roasting process alongside the old reliable hand-rabbed reverberatory furnaces. Some of the members of the party professed to recognize the Coeur d'Alene ore in some of the bins; others of the party were not so sure, although they had seen it in place only a short time before. Dr. Raymond, however, relieved the gravity of the situation by remarking as the party stepped aboard the lift to descend to the floor below, that he hoped that we would all recognize the lore of smelting.

The special car was coupled to the 5 p. m. train for Colorado Springs, where the party reunited and left that night for Chicago. The stay in Pueblo was most enjoyable, and the members of the party wish to express their appreciation of the courtesies shown them by the managers of the several plants, who, so far as possible, personally conducted the party.

JOHANNESBURG, TRANSVAAL.

Transvaal Tin.—A Geological Survey Memoir.—Public Criticisms.—New Modderfontein's Bold Policy. — Sand Filling of Stopes. — Rhodesian Gold. — Survey Connections in Deep Level Mines. — Cooling Towers.

Although the Transvaal cannot be compared with the other British colonies of Australia and Canada in the matter of publishing official reports on its mining fields, it is showing greater enterprise than hitherto. The principal and almost absorbing task of the Geological Survey has been mapping districts irrespective of relative industrial importance. The work to date has covered several mining areas, such as the Pretoria diamond fields, the Lydenburg goldfield, and the Bushveld tin districts. A memoir has just been published on the Waterberg tinfields, which has caused many to regret that matters other than scientific have been treated. The bulk of this memoir consists of a geological report by H. Kynaston and E. T. Mellor, as admirable a treatise as we may always expect from these highly qualified Government geologists. A final chapter, however, is devoted to 'Economic Aspects', and is written by U. P. Swinburne, Pretoria Inspector of Mines. This section is not above criticism; it deals too fully with the items of plant which chance to have been erected (often by amateurs in tin-mining) and too sparsely with mining prospects and conditions. But it certainly has not deserved

the storm of abuse—sometimes bordering on the personal—which has been poured upon it by the interested parties. The criticisms of the report are not of a character to encourage Government officials to extend the policy of dealing with the industrial side of mining. The most valuable feature about the report is that it is a thoroughly honest attempt to describe things as they appear to a mining engineer (who does not claim to be a tin expert). As such, it is much more valuable than many of the more pretentious reports of engineers employed by syndicates. Its chief defect appears to be a lack of pluck (perhaps excusable in view of present 'criticisms' of most moderate and non-committing statements) in failing to estimate future prospects and, when possible, the value and quantity of ore reserves. Records of production—tonnages and yield—would also have been a serviceable addition.

The Waterberg tinfields are the most important in the Transvaal. The large deposits of alluvial tin in Swaziland are the only other occurrences of note in South Africa, excepting the precarious veins to the northeast of Pretoria, and the alluvial deposits near Cape Town. Mr. Swinburne classifies the deposits of the Waterberg under five heads, namely: discoveries in (1) granite, (2) felsite, (3) shales,

Map of the African Goldfields.

(4) quartzites, and (5) alluvial. Classes 1 and 4 are the most significant. The orebodies found in the granite have included some of exceptional richness. On Zadiplaats the ore is found in numerous 'pipes' and chimneys, the deepest pipe extending 400 ft. on the incline, with a working face of 8 by 6 ft. of rich ore. A 10-stamp mill is now at work treating 1250 tons of ore per month, of a value of no less than 8 to 10% tin-oxide. On the farms Roodepoort and Groenfontein there are similar occurrences in the granite, the mill grade averaging lately 6.7%. The chimneys of ore are still strong at 400 ft. deep. In the geological chapters of the memoir, it is pointed out that further facts must be accumulated before the formation of these pipes can be fully explained. It is suggested that they were in all probability formed in an originally deep-seated portion of the granite, which although practically consolidated was still doubtless at a very high temperature and probably at that time had not undergone fissuring to any great extent. Relief of pressure, however, consequent upon the formation of fissures at higher levels, may have initiated the release from the underlying magma of the metalliferous compounds, which would then have ascended in gaseous condition through a practically unfissured zone. The de-

posits of tin in quartzites include the properties of the Weynek Tin Co., Ltd., and the Rooiberg Minerals Development Co. The former contains "two small parallel veins of crushed lode matter," upon one of which sinking has been carried to a depth of 400 ft. This is one of the bodies which was marked by ancient workings. As to the value of the "five different tin-bearing fissures" worked by the Rooiberg company, Mr. Swinburne apparently refuses to commit himself. He devotes two pages to a description of the plant erected and two lines, exactly, to the mine. This is admittedly a flaw in the report, and shows a lack of perspective—or courage. The supporters of alluvial tin in the Waterberg area can find little cause for gratification in Mr. Swinburne's remarks under this head, and it is not improbable that previous reports have been ultra optimistic. So far as we know today, the prospects of alluvial tin mining in South Africa outside the well developed regions of Swaziland, are distinctly poor.

There are few producing mines on the Rand whose progress is watched with keener interest than the New Modderfontein; first, because it is the most easterly important producer of the Rand (the Geduld mill being the only one beyond), and second, because it is rapidly developing into one of the greatest producers in the country. The New Modder (as it is usually termed) has hitherto been milling 30,000 tons per month with 120 stamps and 3 tube-mills. A few months ago an additional 60 stamps and 2 tube-mills were added, making a nominal capacity of 47,000 tons, owing to exceptionally high stamp duties. Now the company is undertaking a bold scheme of advance development, calculated to bring the mine into a fit state for the construction of another mill on the eastern side of the property, at first 35,000 tons in capacity and ultimately 65,000 tons. This will mean that in two or three years, the company will be treating about 1,344,000 tons annually. Practically speaking, the only contingency liable to obstruct these plans is a shortage of labor. It is clear from the review of the position given by Samuel Evans at the general meeting held, at the beginning of September, that there is little to fear in respect to any failure of mine resources. A wholly unofficial estimate of the mill tonnage in the mine may be made at 20,000,000 tons (there are over 1000 reef claims unexhausted) so that with only 75% payable, the mine would appear to be equipped on a highly economical basis, from the standpoint of most profitable life, with the huge crushing capacity mentioned.

Sand from the tailing dump is to be used extensively in the Robinson for stope-filling. The working problem of the mine is a peculiar one. The rich Main Reef Leader, largely stope out, overlies the wide medium or low-grade Main Reef. About 10 or 15% of the ore milled has been drawn from the Main Reef lately and, now that 40 extra stamps have been erected, the percentage is to be increased. When the Main Reef is mined, the total stope width is from 12 to 20 ft., the reef dip averaging 40°. As the hanging wall rock is treacherous, support must be provided. Rock walls and stull-packs have been largely used. These are expensive and material is limited to readily accessible waste from the inter-reef partings. The demand for greater contributions from Main Reef has prompted the management a year ago to make arrangements for sand filling. Steep launders (6 by 6 in.) are carried down, allowing the sand to be easily sluiced from the dump. When the grade of the launder is insufficient to ensure a good flow, more water is added underground. The sand is confined to the stope being filled by rock walls. Over the packs, coconut matting—old filtering material from the cyanide works—is placed to check the sand and allow the water, with very little slime, to flow through. In some parts of the mine it will be possible to utilize the longitudinal and transverse dikes, as containing walls for the sand. This system of sand-filling, practically new upon the Rand, is one that can be extended to numerous purposes, and, now that its practicability has been demonstrated, is likely to be adopted in many mines.

The quarterly meeting of the Rhodesia Chamber of Mines, held in Bulawayo at the end of August, was marked by no announcements of importance. Gold production is not on the increase, among the restrictive factors being the labor

shortage. G. Stewart estimates that fully 10,000 more natives are required. An interesting analysis of the sources from which the Charterland's gold is drawn was given, showing that the production (for the quarter ending June 30), from the mines worked by companies was £327,169 or 49.17%, from the properties owned by companies but worked by tributors, £165,170 or 24.82%, and from the 'small man' mines, £172,993 or 26.01 per cent.

Keen interest is always taken by technical men on the Rand in the results of the surveys in deep-level mines, dependent upon the meridian carried underground by means of plumb-lines in deep vertical shafts. A few weeks ago the connecting levels in the City Deep, Ltd., holed through satisfactorily. The distance between shafts is 5000 ft. and the two shafts are about 3000 ft. deep. In this case the survey was carried on under great difficulties owing to the water raining down. In one shaft there was a considerable convergence of the lines. Details of this survey, however, are not available as in the more recent instance of connecting the Brakpan shafts. There the orientations determined have been found to check up with astonishing accuracy—due largely, no doubt, to good luck, but nevertheless well deserved by the extreme care and skill with which the operations were conducted. It is to be hoped that a scientific description of the work may be placed on record. One shaft was 3700 ft. deep and the other a few hundred feet less. No less than 28 plumb-lines were used, these being fixed in notches in straight edges, placed at the ends of the shaft. For the determination of the mean position of each line, a shadow was thrown on a screen so that the swing was magnified and the extremes easily marked off. Current reports of the work being vague, no account can yet be given of the detailed arrangement. Upon connecting between the two shafts, a distance of 4618 ft., the error in the co-ordinates is stated to have been 0.2 in.—indicating a more perfect connection than one would have any right to expect, whatever the precautions taken to ensure the greatest possible accuracy of observation.

A novel type of cooling tower has been brought to the attention of Rand engineers by John Roberts, Borough Engineer of Durban, who read a paper on the subject before the South African Association of Engineers at the last meeting. The principal features of the tower are as follows: It is built of rectangular frames, without any convergence upward, forming a structure 200 ft. long, 20 ft. wide, and 50 ft. high. The distributing material (brushwood, as usual), does not extend to the bottom of the tower, but there is a space below of 8 ft. The brushwood fills the entire space above as uniformly as possible, for a height of 14 ft. The water has thus to be pumped against a static head of 21 ft. Special provision is made to take full advantage of prevailing winds by doors which can be opened. When open on one side, the bottom of the tower is closed on the other, so that the loss of water is reduced. The most ingenious feature of the plant is the distribution system, which ensures the water being dropped over the brushwood in a finely divided state. The water is led along the length of the tower in ordinary launders, feeding cross troughs, the bottom of which are drilled with holes about $\frac{1}{2}$ in. diam., and fitted with brass tubes about $\frac{3}{4}$ in. long. At a distance of about 6 in. below the tube a round piece of metal of just the size of the latter is supported so that the stream of water impinges upon it and breaks up in a surprising way. The water, indeed, leaves the disc in the form of a thin sheet. Consequently, cooling starts immediately. The question has been raised as to the efficiency of this scheme with water containing quantities of sulphate and carbonate of lime. Incrustations in the service launders and pipes of Rand cooling towers are serious in their effects.

Among the passengers on the ill-fated *Waratah*, which has now been missing at sea for over a month, is J. T. Carrick—a Rand geologist of high standing. Mr. Carrick has done a great deal of useful work in South Africa. Under his guidance the bore-holes of the Western Rand Estates were sunk, proving the probable extension of the Main Reef Series between Randfontein and Potchefstroom. His geological map of the West Rand is the standard compilation for this district.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Abbreviating Code Messages.

The Editor:

Sir—The telegraph companies' side of the message transmission and tariff question, discussed in your issue of August 21, was put very clearly to me this morning and it seems only fair that it should be made public.

"You should know," the manager told me, "that between important points there is what we call a 'bonus line'. The best operators only are employed for sending and receiving on this line. The minimum shifts' work is 350 messages per shift, after which each operator receives 1c. per message. Knowing this," he continued, "you will readily see that speed is the main thing. The receiving operator is not supposed to 'cut in', but to take it the best he can. Even at this time of the year when the aurora borealis adds and removes dots and dashes from the messages, the pressure of accumulated telegrams is too great to permit of stopping for corrections. From the time the operator 'sits in' at eight in the morning, not an instant is lost."

From this I gather that the greater the volume of business the greater the percentage of errors and naturally, the less the telegraph company is to blame. Poor company! Is there no way in which these interested can work together to take away from the lately merged Western Union-Postal company a part or all of its business, turning it over to the post-office? What should be the first step?

MARK R. LAMB.

Milwaukee, Wisconsin, September 25.

Turquoise.

The Editor:

Sir—On page 434 of your issue of September 25 you mention under the above headline some prices presumably paid for the various qualities of turquoise in the East. Being one of the largest buyers of turquoise in the East a few explanations from me in regard to its value may be welcome to some of your readers.

The sale of clear turquoise is limited, but a hard, deep blue material brings easily \$10 per lb. Turquoise matrix, however, has become a staple article with every jewelry manufacturer making a line of goods in which opaque and carbuncle cut stones are used. There is, therefore, constantly a good demand for turquoise matrix and its cutting and polishing is an established industry, the rough material being bought accordingly in large lots. There have been shipped, however, during the last 12 or 18 months considerable quantities of low-grade material, discolored, soft, or chalky turquoise with porous or otherwise undesirable matrix. Such material is a drug on the Eastern market and has no value at all. The lowest price for turquoise matrix, which, when

cut is a gem, may be set at from \$2 to \$3 per lb., according to the amount of waste. The chief requirements of a good grade of turquoise matrix are that the turquoise matter be of a clear, deep blue, and the matrix dark brown and as hard as the turquoise. If the matrix not only surrounds the blue turquoise matter but permeates it in all directions in vein or cobweb like fashion, the material will easily bring \$5 per lb., and miners having a good grade of turquoise matrix can sell the output of their mine on a contract plan. There is no longer any uncertainty as to large quantities finding a ready market. It must be remembered, however, that the Eastern trade desires only the very best material now, and if miners want good prices they should select their turquoise matrix carefully before shipping.

E. SCHAAF-REGELMAN.

New York, October 7.

Free Settlement Method of Separating Slimes.

The Editor:

Sir—In your issue of September 11 is an article by H. G. Nichols, under the above title, which I have read with great interest. The amount of moisture (27%) retained in the thick pulp removed from the bottom of the separator is certainly most satisfactory, and the apparatus, in this respect, compares favorably with the different types of vacuum filters. The subsequent procedure in dealing with this retained moisture does not, however, seem (at any rate theoretically), to be as good as the displacement method used in vacuum filter practice. This remark applies more especially to the cyanide loss incurred in cases where strong solutions are necessarily employed. The percentage of gold and silver recovery depends principally upon the ratio of solution to dry slime in the pulp fed to the separator, and the amount of weak solution used for washing down the pulp into the second separator. The percentage of cyanide loss is independent of the density of the pulp, provided the same initial strength is employed in every case. Let us assume the hypothetical case of a pulp consisting of 250 tons of solution to 100 tons of dry slime. Suppose that 400 grams of silver per ton of dry slime have been dissolved, and that the strength of the solution entering the separator is 3 lb. of KCN per ton; then the silver contained in each ton of solution will be $\frac{400}{2.50} = 160$ grams. Supposing the amount of moisture removed from the bottom of the separator to be 27%, then each 100 tons of dry slime will carry with it 37 tons of solution; and as each ton of solution contains 160 grams silver, the total amount of silver removed from separator No. 1 to separator No. 2 = $37 \times 160 = 5920$ grams. Now if three tons of weak solution are employed to wash down each ton of dry slime from No. 1 to No. 2 separator, there will be used for 100 tons of slime, 300 tons of such solution. This amount, plus the 37 tons of moisture, gives a total of 337 tons of solution. If the wash solution has been perfectly precipitated, the silver contents of the whole solution will be the 5920 grams above mentioned, or each ton will contain $\frac{5920}{337} = 17.567$ grams per ton. The amount of moisture contained in the pulp finally discharged will be, as before, 27%, or 37 tons per 100 tons of dry slime.

The ultimate silver loss is, therefore, $37 \times 17.57 = 650$ grams, which is equivalent to a recovery of 98.375% on the original total silver content of $100 \times 400 = 40,000$ grams.

Now, if the cyanide content is 3 lb. of KCN per ton of solution, the amount of KCN contained in the solution discharged as moisture from No. 1 separator will be $37 \times 3 = 111$ lb., and the amount of solution drawn off through the suction of No. 1 separator will be $250 - 37 = 213$ tons. But 250 tons of solution are required to maintain the volume of the strong solution for agitation purposes, therefore, 37 tons can be taken from the solution obtained from the suction of No. 2 separator. Now, No. 2 separator obtains 37 tons daily from the moisture introduced with the pulp from No. 1, and loses 37 tons daily in the form of moisture going out at its own discharge. It is plain then that the 37 tons withdrawn to replenish the solution drawn from No. 1 must be made up with water introduced into No. 2. Now, since the solution in No. 2 separator is composed of equal parts of solution from No. 1 and of water, it is clear that its strength must be one-half of that of the solution introduced from No. 1, or in other words, 1.50 lb. KCN per ton. It follows that the 37 tons taken from the suction of No. 2 to make up the volume of the strong solution, contain $37 \times 1.50 = 55.50$ lb. KCN, while the cyanide contained in the solution discharged as moisture in the pulp leaving No. 2 also amounts to 55.50 lb. The net loss of cyanide is, therefore, 55.50 lb. for each 100 tons of dry slime, or 0.555 lb. per ton. This amount, at 18c. per lb., represents a loss of 9.99, or practically 10c. per ton of slime handled.

It may be urged that the vacuum type of filters do not successfully displace the solution content of a cake during the process of washing, and on this point I am not in a position to speak authoritatively, but what I do wish to show is the fact that low moistures such as Mr. Nichols has obtained, though excellent in themselves, are not necessarily a guarantee of the very best work.

S. RIVERS BAILDON.

Pueblo, Colorado, October 1.

Geological Survey of India.

The Editor:

Sir—In view of the recent attacks made in the London *Mining Journal* on Mining Administration in India, and also both directly and indirectly on the Director of the Geological Survey, we have deemed it advisable to send you the following extracts, one of which is taken from the *Mining Journal* of June 26, 1909, page 801, and the other from the published evidence given by Sir Thomas Holland before the Royal Commission upon Decentralization and published in Blue-book Cd. 4369 (Vol. X of Minutes of Evidence, page 47):

From the *Mining Journal* of June 26, 1909, p. 801, leading article headed 'Mining Administration in British India'.

"We cannot close our observations on the evidence tendered to the Commission without noting the light thrown by the report on the sincerity of Sir Thomas Holland's attempt to suggest that we had imputed

corruption to Government officials in India. As an argument against the establishment of a separate Provincial Survey, the Director of the Geological Survey said: 'If I transferred an officer, say, to Burma, or any province beyond my control, and he was the officer who governed the granting of mining concessions, I have not the slightest doubt that within a year, if he had only ordinary intelligence, he would discover that his salary *would** be only a fraction of his income'. We do not remember even to have seen the chief of what is professedly a scientific body so frankly confess his distrust of his colleagues' honesty and professional pride".

Evidence of Sir Thomas Holland, Director, Geological Survey of India, published in Blue-book Cd. 4369, being Vol. X of the Minutes of Evidence taken before the Royal Commission upon Decentralization in India, p. 47:

Question No. 43,455: "Is not an officer who has to deal with mining concessions in any part of the world subject to great temptation?" "Yes; if I transferred an officer, say to Burma, or to any province beyond my control, and he was the officer who governed the granting of mining concessions, I have not the slightest doubt that within a year, if he had ordinary intelligence, he would discover that his salary *need** be only a fraction of his income".

By changing one word in quoting the Blue-book, the *Mining Journal* has altered the whole meaning of the remarks made by the Director. In view of the comments made, it is for the *Mining Journal* to prove that this misquotation is accidental. Having regard to the claim of the *Mining Journal* that it "circulates all over the world", the writer of the article must know that it will be read by many to whom the blue-books are not accessible, for no assistance has been given by a reference to the particular volume in which the Director's evidence is recorded. As the inaccurate quotation has already received a start of some weeks before reaching us in India, we shall be glad if, by publishing this letter, you will assist in preventing any further dissemination of a grossly unjust insinuation.

With this sample before them, we can safely leave your readers to estimate the value of the attacks on the Indian administration recently made in the *Mining Journal*. Needless to add, the relation between us and Sir Thomas Holland is one of perfect and mutual confidence. We have been unable to communicate with three of our colleagues, who are at present absent in the field, but we are convinced that if they had the opportunity they would join with us in appending their signatures to this letter.

DRILLING IN ALLUVIAL GROUND IN ALASKA.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

At Nome the use of the drill in prospecting is fully appreciated; in fact, drills have been used more generously than wisely in many instances. Drilling, like sampling, can be done so carelessly as to be worse than useless. That describes some of the results of expensive work on the Seward Peninsula. The old blunder of taking the arithmetical average of assays without regard to the width of ore sampled at different places has been duplicated by the averaging of the yields from bore-holes without reference to the varying depth. Thus, a yield of 80c. per yd. from a 30-ft. hole has been averaged with the 20c. from a 70-ft. hole, giving $20 + 80$ divided by 2 as the result, or 50c. per cu. yd. If the geometric mean be taken, with an eye to the fact that one hole is more than twice as deep as the other, the true average is obtained. In this case it is 38 cents.

A Keystone drill that is worth \$1300 f.o.b. at Beaver Falls, Pennsylvania, with proper allowance for wearing parts, will cost \$2400 at Nome. There are fully 25 of these machines on the Seward Peninsula. On Ophir creek, at the upper line of Claim No. 2, I saw a hole started by a Keystone No. 3 machine. The casing was first pushed by a driving clamp for $3\frac{1}{2}$ ft. into the creek-sand, striking some gravel at the bottom. Then the clamp was raised and about 5 gal. water was poured into the casing, preparatory to commencement of the drilling.

Drilling can proceed even in winter. The Keystone drill employed on lower Thanksgiving creek, in the Hot Springs district, not far from Fairbanks, was in use up to January 1, 1908, and was started again at the end of February; thus the drill was idle only two months. The drill is combined with a traction engine and either can be thrown into gear. The machine is easily moved after the holes are drilled; in soft ground an extemporized track is made by laying down a couple of 4-in. poles; in winter a $\frac{1}{2}$ -in. angle-iron 2 in. wide is affixed across the tire of the rear or drive wheels. The tires are 16 in. wide. The front wheels are 10 in. wide and in the centre of the tire there is a rib projecting one inch. In summer the crew consists of three men; in winter, four are needed, the extra man being engaged in hauling ice or water for the boiler. When I saw the drill in operation, the foreman was getting \$8 per day; the panner, \$6; and the fireman, \$5. In each case \$3 must be added for board. The fireman helps the foreman in sharpening tools, handling the sand-pump, and so forth. A 6-in. casing is used. Only extra heavy casing should be used in the North. The casing is driven only a length (5 ft.) or two from the surface, the remainder of the hole being in frozen ground, requiring no casing. Speaking generally, it is advisable to use a casing for the entire depth of hole, because the varying proportion of ice may cause the formation of a pot-hole. If the ground is thawed deeply, a casing is inserted all the way. At times in summer the surface water is warm enough to thaw the frozen ground and the sides of the bore slough so as to spoil the sampling. The remedy is to use a casing all the way

down. As the hole is made, the débris is pumped. The sand-pump is a hollow cylinder, 8 ft. long and $4\frac{1}{2}$ ft. diam., equipped with a plunger and valve. The plunger is raised rapidly to create a vacuum and suck the stuff at the bottom of the hole into the tube, which is then lifted and emptied into a wooden tank. From this it is taken by the panner, a man whose duty it is to wash the products of drilling. He does it with an ordinary pan, saving the gold concentrate extracted from the sample obtained at each successive stage of the drilling. This gold is subsequently dried, blown clean, and weighed.* It is well to wash the bedrock separately. The driving-shoe, which forces the drill into the ground, is $7\frac{5}{8}$ in. diam. The casing is pounded by the driving-clamp attached to the drill-stem. A good operator will be careful not to injure the threads on the casing and will use graphite or oil to lubricate. Such an operator was Bernard Estoy, the foreman in charge on Thanksgiving creek in August 1908. He drilled 40 holes, averaging 25 ft. each; at a cost of \$1.01 per ft., including all costs and break-downs. This was in the heart of the northern wilderness.

To A. V. Thorns, manager for F. G. Manley, I am indebted for the following details concerning the cost of operating a No. 3 traction Keystone drill in the Hot Springs district, from February 10 to September 21, 1908. The total cost for labor and supplies, including all repairs, moving drill eight miles, hauling wood and water during the cold months, was \$8419.25.

| | |
|--|-----------|
| Total drilled | 9054 ft. |
| Average cost per foot..... | 93c. |
| Average depth of holes..... | 20.64 ft. |
| Average cost per hole..... | \$19.22 |
| Average distance drilled per day, including repairs and moving. | 49.5 ft. |
| Deepest holes | 115 ft. |
| Shallowest holes | 10 ft. |

The ground drilled consisted of frozen clay, gravel, and angular rock. Frequently in the months of February and March, the drill was in operation during severe weather, as cold as 40° below zero, with $3\frac{1}{2}$ ft. of snow on the level. The driller received \$8 per day and board; the helper, \$6; the panner, \$6 also; and the extra man \$5 per day, with board. The three men first mentioned were employed steadily; during the winter months the extra man is required all the time and during the summer he is employed part of the time.

These costs are exceptionally low and should be taken as indicating what can be done under the most favorable conditions, not as an average likely to be attained by a newcomer. At Nome drilling in frozen ground, without a casing, has averaged \$1.50, but on the whole the total cost of drilling, with casing, is nearer to \$3 than to \$1 per foot in Alaska.

It is advantageous to use the drill for testing purposes during the winter, but the results are apt to suffer in accuracy owing to the difficulty of panning. On Thanksgiving creek the equipment included an 8 by 10 ft. portable tent on poles and a Yukon stove

*A small portable balance made by H. Kohlbusch, of New York, is widely used for this purpose.

laid on two poles across the floor of the tent, so that the stove was moved with the tent. Water was heated by steam coming from the boiler, the panning-tub being placed on the stove. The small quantity of water and the re-use makes it muddy, hindering the panning. An extra man is employed to bring in fuel and ice.

A. L. Hamilton, of Fairbanks, stated to me that in drilling with a No. 3 Keystone he got live water in every case by penetrating 12 to 15 ft. into the bedrock. In frozen muck he has made 135 ft. in 11 hours. On Dome creek, at No. 11 Below, a shaft was sunk 148 ft. and ooze or mud rose from the bottom filling it for 75 ft. On No. 7 Below also 'heaving' bedrock

Keystone Drill at Work on Ophir Creek.

was struck, rendering it impossible to operate; the timbers were sheared and the drift warped. The prospecting drill is most serviceable in enabling operators to obtain, at small expense, the information that they should possess before they go to the larger expenditure involved in shaft-sinking.

It is a common practice to thaw ahead of the drill. For this purpose a 'steam-point' 5 ft. long is used, with pipe that can be lengthened. The 'point' is dropped down the hole and left there for not more than five minutes; a longer interval will make the bore larger than the casing.

Looking at the coarse gold lying on the bedrock of many of the Alaskan diggings, the question arises whether the pump could suck such heavy particles from the bottom of the hole. Yes; pieces of gold weighing an ounce have been raised. It depends

upon the particles finding their way to the centre of the bore. However, the chief use of a drill is not only as a sampling device, but to ascertain the depth to bedrock and the character of the deposit, especially to find out whether the ground is frozen or thawed. When the drill is intended to yield samples of the ground, it is imperative that the hole be cased for its entire depth.

The testing of ground by drilling for a purchasing company should not be directed by the promoter or the owner, but by a representative of the purchaser. That is the A. B. C. of serious prospecting, but it has been disregarded. Next, the drilling should be done under the charge of an experienced man, not a carpenter or an electrician who never saw a drill before. This also is a simple idea not often put into practice. Finally, having drilled carefully and honestly, the record must be kept systematically and platted on a map accurately. If not, the results will be confused and misleading.

DETERMINATION OF SILICA.

A method for estimating silica in ores, endorsed by the United States Steel Corporation, is as follows: one gram of the sample is transferred to a porcelain dish, or a beaker, with watch-glass cover, and 20 c.c. of strong hydrochloric acid added. A gentle heat is applied until the ore is dissolved, and the solution is then evaporated to dryness, unless it has been conclusively shown to be unnecessary. To the residue, which should not be heated above 120° C., 15 c.c. of dilute hydrochloric acid (1 part acid to 1 part water) are added, heat is applied until the salts are dissolved, and the solution is diluted with hot water. The precipitate is filtered off, washed, ignited at the highest temperature of the blast-lamp or muffle-furnace for at least five minutes, cooled, and weighed. To the residue in the crucible one or two drops of strong sulphuric and 5 c.c. of hydrofluoric acids are added, and the solution is evaporated to the expulsion of sulphuric acid. The residue is ignited as before and again weighed; the difference between the two weights is silica.

Free timber to the amount of nearly 7,000,000 bd. ft. was given away for domestic use of people in the California National Forest district last year. F. E. Olmsted has just compiled a statement showing that the exact amount given away was 6,885,287 ft. board measure, having an estimated value of \$14,262.20. The Forest Service grants free timber to the value of \$20, based on its value standing in the woods, to settlers, farmers, prospectors, and others for domestic use, and to school and road districts. This free use is confined to those who need it for domestic purposes. It is not given away for any kind of commercial use.

Coke production during the four weeks in August in the Connellsville district, was 1,605,185 tons, more than double the product for the corresponding weeks in 1908. The pig-iron production for the month, 2,246,480 gross tons, approximates the record production of August 1907, the output of the Pittsburg district for the past month even exceeding the August 1907 output.

PROTECTING STEEL FROM CORROSION.

By R. B. WOODWORTH.

*The use of steel in coal mining operations has been objected to on the ground of the presence of acid found in the waters. This condition obtains also, and probably to a larger extent in the copper mines, and in iron mines carrying pyrites. Such steel as has already been installed in the mines of the United States has given satisfaction without any serious corrosion, and without any protective treatment of the steel other than the use of good preservative paint. In wet mines in England steel girders are frequently tarred before being put in, but the actual loss from corrosion is so small as to be a minor quantity, even when the steel is not painted. In dry mines there is not much danger of any serious corrosion, but in conditions subject to moisture, and to varying temperatures, attention must be paid to this point. In my opinion true economy will be found in the painting of all steel for underground mine operations with one shop-coat of good paint and with at least one field coat. If these are well worked in the steel should need no further attention for years.

Careful investigation has been made as to the kind of paint which may be depended on for service in contact with acid waters, and I have conducted laboratory experiments to demonstrate the fitness of different pigments for this purpose. I agree with the conclusion reached by A. S. Cushman, of the Scientific Section of the Paint Manufacturers Association of America, that steel should not be painted with carbon paints in the manufacture of which sulphuric acid has been used, and the use of coal-tar products is therefore to be avoided. The natural carbons, such as graphite, and hydro-carbons, such as asphalt and gilsonite, may be recommended for the second-coat work if properly ground and mixed with a good vehicle. For the first coat, pigments should be used of an inhibitive character. The oxides of iron, such as Venetian reds, are usually manufactured by chemical processes, and their use is to be avoided, though a good natural oxide of iron paint may be used under dry atmospheric conditions. For first-coat work zinc chromates should give good service, but probably the best to use is red lead and oil, which has been demonstrated to be a first-class pigment for preservative treatment in most situations. The red lead should be pure and mixed in the proportion of not less than 15 to 16 lb. of red lead per gallon of oil. The oil should be pure, and in my judgment raw oil is better than boiled. The matter of vehicle is of some importance, and care should be taken to see that the pigment is thoroughly mixed before application. Red lead is a heavy pigment and settles quickly, necessitating the mixing of a new lot if it has stood any length of time. The settling may be retarded by the use of barytes or 'asbestine', and the use of the latter is to be recommended by reason of its permitting a firm hold on the pores of the steel. For first-coat work, therefore, a mixture of red lead, oil, and asbestine, in the proportion of at least 15 lb. of red lead and 2 lb. of

asbestine per gallon of oil, with sufficient japan dryer to work well, may be recommended as probably the best which can be had under present conditions; and for the second coat either silica-graphite or Mexican graphite; both coats to be well worked in, and the first coat be thoroughly dry before the application of the second. The theory on which this preservative treatment is recommended is based on the use of a practically inhibitive pigment to prevent the inception of corrosion in the steel, and the use of a second coat to protect the first atmospheric and temperature conditions, and to fill up thoroughly any vacancies or voids which may occur in the first. Inasmuch as the particles of the red lead and the graphite are extremely small, the combination of these two coats should give a film practically impervious to atmospheric moisture, or to acid-bearing waters.

We live in an age of steel. The large demands made on our timber resources and the increasing scarcity of timber suitable for the heavier constructions of underground mine-work, make the consideration of a substitute a matter of vital moment. Experience in varied lines of construction has shown steel to be the one material known in the engineering world which by its flexibility and convenience of use can replace wood fully and satisfactorily. It can be perfectly adapted to all phases of construction; it is easy to obtain and convenient to fabricate and erect, and its long life under all conditions of moisture temperature, and stress amply compensates for the increased cost of its first installation. Reduction in weight, economy in erection, the possibility of re-use, and its fire-proof character, are but a few elements of advantage. The application of steel to mine timbering is but in its infancy. Considerations of economical operation will necessitate larger use of steel in the future, and the mine owner will be wise who looks beyond present first cost to ultimate economical operation and steady uninterrupted returns on investment.

Aluminum is used in iron and steel works for removing oxygen from the oxides of iron and other substances, the heat generated being so great as to raise the temperature of large bodies of iron. It also has the power of combining chemically with the gases imprisoned during the cooling of the metal, thus preventing porosity. For these purposes the metal is either used in the form of an alloy known as 'ferro-aluminum', or as the pure metal, either in the granulated or bar form or in small pieces weighing uniformly one-eighth ounce or one-fourth ounce each. This property of keeping molten metal hot or of raising the temperature of a molten metallic bath has been utilized in the thermit welding process, invented by Goldschmidt. In this process aluminum and iron oxide are intimately mixed in a finely divided state and ignited by means of a fuse. The heat of combustion in the ensuing reaction raises the temperature of the casting to the welding point. The reaction takes place in a funnel-shaped crucible, from which the fluid metal resulting from the reaction is run into a suitably shaped mold formed around the area of the joint to be made, which is pre-heated by means of a blow-lamp to avoid chilling the first lot of metal coming through.

*Abstract from paper on 'Application of Steel to Mine Timbering', presented at the American Mining Congress, Goldfield, Nevada.

QUICKSILVER AT HUANCAMELICA, PERU.

Written for the MINING AND SCIENTIFIC PRESS
By LESTER W. STRAUSS.

The town of Huancavelica is situated in Lat. S. 12° 54' and Long. W. 75° 4' (Greenwich), on the eastern slope of the western Cordillera of the Andes, and is the capital of the Department of that name in the Republic of Peru. It is accessible either from Pisco, a port on the coast one day by steamer south of Callao, and then five days on horseback (including half a day railroad ride from Pisco to Ica), the last part of the trip being over the Cordilleras; or from Callao, taking the Peruvian Central railroad to Huancayo—a day and a half ride—and then two days on horseback, four days being necessary. The latter route is preferable, the former having been used prior to the time when the railroad reached Huancayo. Huancavelica is in a narrow gorge through which passes the river of the same name, and is surrounded by high mountains. The altitude of the town is 3740 metres (12,267 ft.) above sea-level, while the mines are at 4250 to 4390 metres. The climate is healthy but usually rainy, with hail and snow during the winter months (November to May), and the nights are cool and refreshing. The population may be 3000. The industries are agriculture, the raising of llamas, alpacas, and cattle, and mining; the last being at present conducted on a small scale.

The opening of the quicksilver deposits resulted, according to history current in Huancavelica, upon a trip of an archbishop who was traveling eastward to Ayacucho in 1532. Stopping for the night in an Indian's hut, he was offered 'silver-water' to wash with. Recognizing native mercury, his questions led to the Indian's showing numerous 'wells' which interested the archbishop, who sent specimens of cinnabar and native mercury to Spain. The Spanish Crown immediately took steps to develop the industry, which began production January 1, 1571. Mariano Eduardo de Rivero y Ustariz, in Vol. II, 'Colección de Memorias Científicas' (published in 1857), states that an Indian advised Amador Cabrera, in 1564, of the quicksilver ores, and the latter sold the Santa Barbara mine, in 1570, to the King of Spain for 250,000 ducados. It is certain, however, that Viceroy Francisco de Toledo, who reached Lima in 1569, and later became "distinguished in founding the infamous colonial system", claimed all the mines for the Spanish Crown, allowing some rights to the discoverers and their descendants. At times the mines were worked for the Crown, and in other periods by the 'Gremios de Mineros' (a sort of Miners' Guild or Union which existed in each mining district and had an exclusive monopoly in making its own laws, each being suited to the conditions prevailing in the particular region), who were obligated to sell their product, either weekly or monthly output, at a price varying from 50 to 85 pesos per quintal. This resulted in a profit for the Crown, and a loss to the 'Gremios'. This body was poorly organized, and the members mined unsystematically, extracting rich ore, robbing pillars, and filling up abandoned workings, so that the mines were left mainly a mass of holes, with some extensive openings,

which resulted later in rendering the workings dangerous. In one of the workings a collapse buried 100 Indians. From 1790 to 1813 the mines were worked by the Government. Previous to, and for some years after, the independence of Peru (July, 1821), no work was done. In 1836 a company was formed to produce sufficient metal for consumption in Peru, but was dissolved in 1839, and later poorly re-organized, so that in two years' time it failed, after ruthlessly gutting the workings. Later the properties were rented by the Government. Lack of sufficient capital and of efficient management, as well as the discovery of mercury in California, coupled with political strife in the country, were the causes for the decadence of the industry.

In 1784 work, under the director Pusterla, was begun in San Juan de Dios, exploring the zone in various directions. It was noted that the mineral here

Map of Central Peru.

occurred in bunches, and that below the tunnel Señora de la Bélen, in the deeper part of the hill, there was good mineral. He was of the opinion that work to the south on the zone would be preferable to the north. Rivero gives an extract of a report, made in 1785, which stated that the entire zone is metalliferous, with cinnabar more abundant in one part than in another, and in places, where the mineralization is narrow, the ore appears more abundant than in the wider parts. In 1790 Baron Nordenflicht writes that the Santa Barbara workings are stated to show the zone to be 80 varas (50.4 metres) wide, striking N. N. E., the sandstone appearing both fine-grained and coarse-grained, spattered with cinnabar. Rivero describes his entrance into the workings in 1846, through the tunnel, Señora de la Belén. After a description of the drifts, winzes, and stopes entered, he states the zone to be 50 varas (41.5 metres) wide, carrying cinnabar disseminated in the sandstone. In the region of the workings known as Carlos III, he found cinnabar in the sandstone with

walls of white limestone and bluish marl, the width of the mineralization being from 40 to 50 varas (33.2 to 41.5 metres). The workings show enormous stopes, and figures prove that from 1690 to 1722, 1,447,845 pesos were spent in labor and materials to support the walls, and other workings. In summing up his study, Rivero states that the zone (he calls it 'man-to') varies between 70 to 80 varas (58.8 to 67.2 metres) containing approximately 1% mercury on an average.

During the rule of Spain the provinces were made to contribute to the support of the mines, either in sending money or Indians (mitayos). These unfortunates were practically slaves. The contributions per year amounted to 40,000 pesos and 165 Indians. In 1846, 46 mines were producing, the ore being smelted in 111 furnaces. The Trinidad and Quirar-quichqui mines yielded ore which gave 40 to 45 lb. of mercury per furnace-run, that is, 1.3 tons of coarse and fine ore.

According to the books kept for the Spanish Crown, the production of quicksilver from 1571 to 1790 inclusive (220 years), amounted to 104,046,931 lb., which, valued at 0.73 peso per pound, makes a total value of 75,954,257 pesos. From 1791 to 1813 inclusive (23 years), 6,976,610 lb. were produced. No detailed records are obtainable for the producing periods from 1836 to 1839, but Rivero states that 120,000 lb. were probably produced yearly. The periods 1814 to 1835, inclusive, were non-producing, due to internal friction which led to the independence of Peru in 1821, and the following years were occupied in establishing the republic. From 1839 up to the present, no data exist, but it is probable that 1,000,000 lb. would be approximately the production. The total amount of mercury won has been:

| | Pounds. |
|------------------------------|-------------|
| 1571 to 1790 inclusive..... | 104,046,931 |
| 1791 to 1813 inclusive..... | 6,976,610 |
| 1836 to 1839 inclusive..... | 360,000 |
| 1840 to 1909, estimated..... | 1,000,000 |
| Total | 112,382,541 |

The above does not include the mercury stolen.

It is interesting to note that the silver mines in Peru required 563,100 lb. of mercury yearly in the production of 562,000 marcos (4,496,000 oz.) of silver, indicating a loss of 1 lb. per marco, or 2 oz. mercury per ounce of silver. The figures given represent the years 1800 to 1804 inclusive.

The cinnabar belt is said to be about 60 kilometres long, in a northwest and southeast direction. The production, as given above, has come from the Santa Barbara mines (southeast 2.7 kilometres from Huan-cavelica), occupying a small part of the entire area; here the mineral has appeared in workable quantities, probably due to the close proximity to the basalt, which appears immediately to the west. The mineralization is intimately associated with sandstone, limestone, and calcareous conglomerate, which have suffered folding, due, no doubt, to the later eruptives—basalt, porphyry, and andesite. The cinnabar in the Santa Barbara mines, which are the workings referred to throughout this article—appears to have impregnated the sandstone, also occurring as bunches in the same, and as veinlets in the fractures and cavi-

ties in the limestone, and less frequently in the conglomerate. The ore is sometimes found as a powder bespattering the gangue rocks. With the cinnabar and native mercury are associated galena, blende, pyrite, arsenopyrite, and realgar in small amounts. The principal distribution of the cinnabar is in the sandstone. Picked samples of ore run up to 10% of mercury. According to Umlauff (Boletín del Cuerpo de Ingenieros de Minas del Perú, No. 7, published July 1903), the average assay of the samples taken from the workings already exploited, showing mineralization, not from the mass of sandstone and limestone in which the mineral is impregnated, gave 2% mercury. The nature of the mineralization is such as to cause one to expect irregular distribution of the ore throughout the zone. Its deposition was affected by the character of the rock. In the sandstone it occurs in the minute cavities between the grains, and in the white limestone following the joint planes or cleavage, or depositing on the walls of the cavities in the same. The limestone contains Cretaceous fossils. The andesite, which occurs in masses of irregular size through the sedimentary rocks, is barren of cinnabar. Mercury-bearing sandstones or limestones frequently surround these masses, which, on account of their imperviousness, blocked the passage of the mineral solutions, thereby causing deposition.

The origin of the ore is undoubtedly due to thermal action. It is apparent that the sandstone afforded a channel for the passage of the solutions, and from it they extended to the limestones. The intrusion of the basalt was the cause for the circulation of the thermal solutions which produced the ore and the springs. It is conceivable that the cinnabar may have been precipitated from solution by reduction of pressure and temperature in its upward course; also through chemical action, in the oxidation of the H₂S gases and the reactions of the alkaline salts in warm, diluted solutions. The native mercury is probably the result of the chemical activity of acid waters upon the cinnabar. There are several springs close to the town where the temperature is usually 82°F. The deposition of calcium carbonate and oxide of iron is continual, and in places the deposit attains a thickness of 8.5 to 10 metres. The water emits a sulphurous odor. Raymondi gives an analysis of the water from the San Cristóbal spring, on the north side of the town.

The tunnel 'Nuestra Señora de Belén' is 560 metres long, about 120 metres below the crest of the hill; its cross-section is 3 metres wide, and from 2½ to 3½ metres high, being accessible part way on horse-back. Its direction is N. 25° E., and about 286 metres from the portal a cave prevents further entry. This tun-

nel was commenced in 1601, and finished in 1642: it passes through schist, conglomerate, limestone, slate, calcareous slate, limestone, and sandstone. Its driving cost the miner's guild 1,000,000 pesos. Several rich shoots were cut in passing through the mineralization in the sandstone; the face is said to have been driven 100 metres beyond the sandstone, where realgar appeared in considerable amounts. It is stated that the work done is within an area of 60,000 square metres, but no statement is made as to the tonnage this might represent; the average depth worked out might be 150 metres. The deepest workings are 450 metres below the crest of the hill, and about 200 metres above Ulloa, or Poccho tunnel. This tunnel, situated 400 metres southeast of the centre of the town, and 32 metres above it, was selected as a feasible place for driving to cut the mineral in depth. About 2000 metres of driving were estimated as necessary before reaching the zone at a depth of 500 metres before the Nuestra Señora de Belén. It has been driven 150 metres in slate, with sandstone close to the walls. A little sulphurous gas is noticeable. Unfortunately the mine workings, particularly in depth, are not all accessible, owing to the ruthless system of mining done by the 'Gremios de Mineros'. The mines and their output would have been much better had their exploitation been in the hands of strong capital and efficient management. There exists in the National Museum in Lima a plan of the workings.

The furnace used to smelt the ores, both fine and coarse, was invented by Lopez de Saavedra Barba, in 1633. Previous to this the ores were treated in earthenware bowls or trays, which crude process was succeeded by a type of furnace called 'javecas'. Details of these processes are not given, but the production of mercury, during the 62 years that the ores were smelted by these inferior methods, that is, from 1571 to 1632 inclusive, amounted to 31,764,170 lb. The Barba furnace was improved by José A. Bustamente at Almadén, Spain, in 1646, and is in use there at the present time. These improvements consisted in making the furnace larger, widening the openings leading to the aludels, and passing the vapors through large chambers after having been condensed in the aludels. From the aludels the mercury passes to pans, and is finally collected in cast-iron pans in a storehouse. Brushwood was used as fuel, but is now superseded by coal. The furnaces used at Huancavelica were poorly constructed, the stones being porous, the joints loosely plastered over with mud, and the junctions of the condensing-tubes and aludels poorly luted. These defects caused considerable losses in the escape of the mercurial vapors; metallic mercury collected in the crevices of the stones, in the adobe, or mud walls, and luting, and in the straw-roofs housing the furnaces. The escape of mercurial vapors usually sickened the furnacemen. The improved furnace used in Almadén would have lessened the losses and defects. The scarcity of wood accounts for the use of straw and llama-dung and a necessarily smaller furnace to concentrate the heat. The poor quality of fuel burned resulted in part of the cinnabar failing to be decomposed. The furnaces, usually built in blocks of two, were charged

as follows: above the grate or adobe arch, extending over the fire-box, a layer of previously smelted ore was spread, upon which followed a layer of low-grade coarse ore, succeeded by two or three layers of 'bolas', small cakes about 6 in. diam. and 1 in. thick, made of fine ore mixed with mud, so placed as to allow openings for the passage of the heated gases. A tube was suspended in the centre about which low-grade coarse ore was spread, a second tube was placed over the first, and high-grade, coarse ore spread about it, followed by a row of bolas, then by low and high-grade ore, in alternate layers, finishing with fine ore until the furnace was filled to below the openings or tubes leading off to the aludels. Care was taken, throughout the charging, that proper openings were left for the passage of the heated gases. Charging having been completed, the mouth of the furnace was closed. At the present time the charging is done somewhat differently. The bolas are placed on the grates so as to allow for 1-in. openings, and above these coarse ore, 4 to 5 in. diam., is spread, each succeeding layer being made up of smaller material until at the top of the charge the lumps are $\frac{3}{4}$ to 1 in. diam. No tubes are used inside of the furnace. In front of each tube, there being four, each 6 in. diam. and 4.5 ft. long leading off from the furnace top, were a series of bowls or aludels, made of clay 16 to 20 in. long 10 to 15 in. diam. at the widest part, and 5 to 6 in. at the extremities, 14 to 16 in a row, which served to condense the mercurial vapors, the last bowl opening into the air. The operation of charging, distilling, and discharging the treated ore took about 24 hours, of which 10 hours was believed to be the necessary time-allowance for distillation. The amount of coarse and fine ore smelted consisted of 15 cajones, each weighing from 6 to 8 arrobas, 150 to 200 lb., a total of 1.31 tons. Including the bolas, the total charge was 50 quintals (2.5 tons, as 500 bolas were used per charge, and a bola weighs from 4 to 5 lb.). About 1.7 to 2.0 'piaras' of straw (about 3.4 to 4.0 tons) were consumed per charge; at present 300 lb. of llama-dung and 100 lb. of straw are required per charge. A 'piara' consisted of a drove of 40 llamas, each carrying a carga of 100 lb. After closing the furnace top, the straw-fire was started, having allowed openings for the escape of the moisture from the ore, which usually required 3 to 5 hours, according to the carefulness of the 'oyarico', that is, furnace foreman, the amount of moisture, and the condition of the fuel. The furnace help usually inserted a hand in one of the openings referred to, to judge the completeness of the calcining. The smelting, or distilling of the ore was judged through these openings, which also served as draft. They were temporarily closed with mud-balls. The aludels helped to give some idea as to how the heat was passing through the furnace, which test was made by inserting the hand to judge the temperature. When it was estimated that the fire had reached the ore, the door of the fire-box was closed with mud and the enclosed fuel allowed to burn out. The escaping gases, from the fire, passed out through the outlet-tubes and aludels, which latter were placed over tubes of water that served to cool them. After having thus retarded the fire, a wet cloth, tied to a

rope, was used to moisten the top of the first aludel connected with the outlet-tubes. This wetting down was continued until it appeared that no mercury was being volatilized, which observation was made through peep-holes, as well as tested. This test is described later. The top of the furnace was then opened, and also the discharge-holes above the grate, thus cooling the furnace; the mercury was collected according to the amount apparently deposited. This was usually done after every two charges. The interior of the furnace was sprinkled with water, after which the chargers entered to begin the succeeding run. A monthly report for November 27 to December 31, 1791, shows the following figures:

| | | |
|-----------------------------|----------------|---------------|
| Coarse ore treated..... | 10,852 cajones | } 2540.6 tons |
| Fine ore treated..... | 23,023 cajones | |
| Straw consumed | 2,179 piaras | = 4358 tons |
| Charges smelted | 1,287 | |
| Mercury produced | 18,118 lb. | |
| Mercury produced per charge | 14 lb. | |

The 13 smelteries in the vicinity of the town were each under the supervision of a mayordomo, general foreman, who lived at the plant and looked after the furnace-operation in all its details. The 13 smelteries were divided into three departments, each in charge of an overseer whose duties were to note material received and consumed, to watch the cleaning up of the mercury, and to accompany it to the Royal Stores. There was also an inspector who watched the dis-

patch of the coarse and fine ore to the furnaces, noting its quality; received the straw, and so forth. Above all was a director or general manager, who rendered daily accounts of all materials received and consumed, inspected the quality of the ore being treated, assisted in the weekly weighing of the mercury produced, and the like. Each furnace was in charge of a head Indian, whose pay amounted to 4 reales (about 50 centavos) per day. He watched the charging and running of the furnace. The 'oyarico', a free Indian as compared to the 'mitayos', contributed by the various provinces, charged the furnace, taking care as to the proper distribution of the material. He watched the running of the furnace, also urging the furnace-men and peones. The pay was 4 reales (50 centavos) per furnace run. Each 'hornada' (smelt) was made by the 'mitayos', who separated and picked over the discarded ore after a smelt, charged and discharged the furnace, supplied fuel to the fire, and attended to all the necessary manual labor. They worked day and night, receiving 3 reales (37½ centavos) per smelt, that is, 24 hours. Their women helped them, particularly in washing the mercury. A bachelor paid ½ real (6¼ centavos) to a woman who worked with him. The women made the 'bolas', receiving 3 reales for 500.

In running the furnaces many difficulties were experienced with the labor. During the cold nights the men would fall asleep, permitting the fires to go out, thereby cooling the furnace. Upon awakening, they would discharge the furnace and blame the low recovery to the poor grade of the ore. Evaporation of mercury often occurred through carelessness in luting the top of the furnace, or in failing to close the peep-holes when not in use. In testing whether the last of the mercury had been distilled, a stick, coated with mud, was inserted in one of the peep-holes, and after a few minutes withdrawn. If it did not appear whitened with mercury pellets, the process was considered finished; as this test was often done at night, by candlelight or moonlight, the results were not reliable. Furthermore, the men would be half asleep at their work, and would gladly favor discontinuing the firing so as to be able to quit work early. The laborers suited the operations to their own convenience, particularly on night work. Means were taken to reduce this shiftlessness at night by having a special furnace-man pass from furnace to furnace testing the distillation. When it was decided that no more mercury was being distilled, the furnace-top was opened, and within an hour the aludels were separated, provided enough mercury had been collected, and each was washed over a tub to loosen the mercury clinging to the sides. The dirty material caught was afterward mixed in the 'bolas'. This was the only use made of a very small part of the soot or 'stupp'. Below the bowls, or aludels, the earth was cleaned up to collect any mercury which might have escaped. Certain losses were unavoidable here as well as in handling the mercury. The furnace is about 4 metres high from the floor to the mouth, and 4 metres square. The interior is conical in shape being 2 metres in diameter over the arch, and tapering to 50 centimetres at the mouth. There is about a metre of wall enclosing the charge. The

two discharge doors are 20 centimetres above the arch, thus permitting easy removal of the smelted ore; the outlet-tubes, leading off to the aludels, are 30 centimetres above the arch. The fire-box is 15 metres in diameter and 75 centimetres high; the opening is 50 centimetres wide. There are usually four arches, made of adobe, spanning the fire-box. The top and fire-box side of the furnace is enclosed in a crude housing of poles and straw, which serves as a protection from the cold and breaks the effect of undue draft on the fire.

Rivero states that in smelting metals a certain loss cannot be avoided, but with mercury, until the exact conditions are understood, it is not only possible to

Llamas at Pulacayo.

lose much, but all of it, although working conscientiously. If the mercury vapors are not thoroughly cooled within the aludels they evaporate into the atmosphere, and it is possible that millions of quintales, so he says, may have been lost without a trace being found in the region. It was impossible to calculate the losses, as the grade of ore, coarse and fine, and discarded, was not determined. During the operations of the 'Gremios de Mineros', covering a period of over 200 years, abundant rich ore was available which was charged with the low-grade so as to produce mercury as quickly as possible, but in so doing heavy losses were incurred. Rivero is of the opinion that poorer ores were being smelted in 1843, with much more attention paid to preventing losses, which he states were at least 10%. Crosnier, in 1851, puts the loss at 50 per cent.

In Huancavelica 76 furnaces produced 40 to 50 quintales per week, while in Almadén, during the same time 500 to 600 quintales were produced from 16 furnaces, the capacity of these being 10 to 12.5 tons per charge. The ores of Almadén were of higher grade.

In 1792 there existed 18 furnaces belonging to the mines, and 93 to private parties. The former produced 700 lb. per week from 65 to 70 charges, each charge producing from 10 to 12 lb. of mercury. The mine Trinidad Chica yielded from 20 to 25 lb. per charge. The cost to smelt averaged 33 pesos per quintal. With mining charges and other expenses the total amounted to 93 pesos per quintal of mercury. Working all year, without repairs or shut-downs, a furnace could produce 20 to 30 quintales of mercury, assuming the average ore to be smelted, that is, a yield of 14.5 lb. per charge. During the

period from 1745 to 1756 the Spanish Crown paid 74½ pesos for a quintal of mercury; from this one-fifth was deducted for the 'royal account', 2% toward the support of the hospital, and 0.05% for leakage in handling the mercury. The total deductions, 22½%, brought the net price paid to miners to 57.5 pesos. The price was arranged so that the mines in Almadén, Spain, could compete and ship their mercury to South America, thus fostering the home industry. Of the 57.5 pesos received, 27.5 pesos were used in buying supplies, and 30 pesos to cover labor and living accounts. Complaining against this low return of 30 pesos per quintal, when working low-grade ores and suffering from expenditures on the furnaces, the price was raised to 35 pesos per quintal, the Crown keeping the furnaces repaired.

From the description given it is evident that the wasteful practice in smelting the ore must have resulted in higher losses than those indicated by Rivero and Crosnier. Considering the various sources of loss, there are: (1) Crude construction of furnaces, allowing crevices for escape of mercurial vapors. Also poor arrangements for condensing the vapors, and the crude system of luting the connections between the tubes and the aludels. (2) Poor quality of fuel used, not yielding enough heat for the complete distillation of the mercury in the ore. (3) Carelessness of the furnace-men in smelting, as regards watching the fire, openings in the furnace, testing smelting period, and the like. (4) Apparent disregard of the soot produced, which was only treated to a small extent. Permeation of mercury in the ground, as well as in the furnace-walls, was another cause of loss. (5) Intermittent process of

A (upper), Bolas; A A (lower), Aludels; C Outlet Tubes.

View of Upper Part of Furnace.

smelting. (6) Action of the acid waters on mercury.

It is evident that the mercury production resulted only from that caught in the aludels, which served as crude condensers, so little attention being paid to keeping them cold. In Idria, Austria, where wood was used as fuel, and better furnaces and condensing arrangements employed, 20% of the mercury produced was caught as metal in the condensers, but the mercurial 'soot' ('stupp') in the furnace is collected and treated separately, hence it would not be reasonable to expect a better extraction in the Huancavelica furnaces, and it would be fair to allow 80% for losses by evaporation, in soot, and in undecomposed ore. Although this seems a high figure, there appears to be sufficient proof as to its probability. Modern

furnaces should obtain from the ore the high extractions now made in other parts of the world.

Detailed furnace costs for smelting from January 1 to June 3, 1792, corresponding to a production of 98,900 lb. of mercury are given below :

| | Pesos. | Reales. |
|---|--------|---------|
| 'Oyaricos', 6392 charges, at 4 reales..... | 3,196 | .. |
| Furnace help, 25,568 charges, at 3 reales..... | 9,588 | .. |
| Masons and brick-layers on furnaces, 183 shifts, at 6 reales..... | 137 | 2.0 |
| Sorting fine ore, etc., 2503½ shifts, at 3 reales | 938 | 6.5 |
| Mason work on furnaces, 5 shifts, at 5 reales. | 3 | 1.0 |
| 13 reams of paper, at 6 pesos each, for binding 14 books | 108 | .. |
| Repairs to furnace, 42 shifts, at 4 reales..... | 21 | .. |
| Bowls, cloths, and 3 cowhides..... | 12 | 6.0 |
| Total | 14,004 | 7.5 |

STAFF PAYROLL.

| | Pesos. | Reales. | | |
|---|--------|---------|--------|-----|
| 1 director, 26 weeks, at 15 pesos | 390 | .. | | |
| 1 inspector, 26 weeks, at 12 pesos | 312 | .. | | |
| 3 overseers, 26 weeks, at 99 pesos | 702 | .. | | |
| 13 mayordomos, 26 weeks, 11 at 6, 2 at 8 pesos..... | 2,132 | .. | | |
| 1 head foreman, from April 22 to June 3, at 4 reales per shift | 21 | 4.0 | | |
| | 3,557 | 4.0 | 3,557 | 4.0 |
| Furnace supplies and straw, 10,659 'piaras' of straw at 10 reales | 13,324 | 0.5 | | |
| Various furnace parts..... | 158 | 6.5 | | |
| 36 cowhides and 120 earthenware vessels, at 1 real..... | 19 | 4.0 | | |
| 3583 tubes, and 195 covers, at 1 real | 472 | 2.0 | | |
| 33 loads of bowls and poker.. | 21 | 5.5 | | |
| | 13,996 | 2.5 | 13,996 | 2.5 |
| Total | 13,558 | 6.0 | | |

Cost per quintal of mercury produced, 31.91 pesos.

At present the only work going on is that of producing a quintal or two of mercury per month. One man does the drilling and blasting, while two peones pack the ore to the furnace, where they help to charge the ore and bolas, in addition to the regular charger and foreman. The costs of smelting, per charge of 1.5 tons, of coarse and fine ore per 24 hours is as follows:

| | Soles, per 24 hr. |
|--------------------------|-------------------|
| 1 charger | 0.60 |
| 1 foreman | 1.00 |
| 300 lb. llama-dung | 0.60 |
| 100 lb. straw | 0.20 |
| 500 bolas | 0.25 |
| Furnace repairs | 0.45 |
| | 3.10 |

This is equal to 2.07 soles per ton of ore. The production of mercury is about 9 lb. of mercury per charge. Miners are paid 80 centavos per 9 hours, and ordinary labor 50 centavos. The mining costs about 1.50 sol per ton. To erect a furnace costs from 250 to 300 soles (£25 to £30). It is repaired yearly. Outlet-tubes cost 30 centavos each, and last three or four years. Aludels (bowls) cost 10 centavos each.

and must be replaced every four to six months. Freights to Huancayo, the nearest shipping point, cost about 45 soles per ton, or 2.25 soles per quintal. From Huancayo to Callao by railroad costs 35 soles per ton.

The location of the continuation of the railroad from Iseuchaca southeasterly to Ayacucho, has not been definitely decided, but it is probable that a spur will be built into Huancavelica. Meanwhile the line from Huancayo to Iseuchaca, one-third of which is graded, should be open for traffic within three years, and thus put Huancavelica within 50 kilometres of a railroad, which route would be over a good trail, except for the ascent from Iseuchaca and the descent into Huancavelica.

GEOLOGY OF THE COALINGA OIL DISTRICT.

Written for the MINING AND SCIENTIFIC PRESS
By WILLIAM FORSTNER.

It has lately been contended that underlying the Miocene oil measures of the Coalinga oil district, Eocene oil-bearing measures can be traced continuously from the Oil City pool, north of Coalinga, to beyond the Devil's Den. On thus subject I submit the following notes:

The wells of the Home Oil Co., in Oil City, in W. ½ N. W. ¼ section 20, T. 19 S., R. 15 E., are situated in the Eocene (Tejon) formation. The oil in these wells, underlying the Eocene shales, are of Eocene age, and are not the same sands as those from which the wells in the east side field derive their oil, the latter being of lower Miocene (Vaqueros) age. The Kreyenhagen wells, in S. E. ¼ section 32 T. 22 S., R. 16 E., are situated at the contact of the Eocene shales and the underlying Eocene sandstones, and the producing oil sands are of Eocene age. The upper well of the Avenal Land & Oil Co., in Big Tar canyon, in E. ½ E. ½ section 18, T. 23 S., R. 17 E., starts in the formation underlying the Eocene shales, and derives its oil from Eocene sands. The eastern or lower well of same company in same canyon, starts in the Vaqueros; at a depth of 1000 ft. it yielded some light oil, 28°B., whether from the strata underlying the Eocene shale, or from sand strata interbedded with the Eocene shale, is an open question. The Baby King well in N. E. ¼ section 11, T. 23 S., R. 16 E., starts in the Vaqueros close to its contact with the underlying Eocene shale. In Bulletin No. 357, United States Geological Survey, p. 109, it is stated that at 400 ft. 30°B. oil was struck, and at 1100 ft. 18°B. oil. At present some heavy oil is found in the water flowing out of the well. As the log of this well is not at hand, it is impossible to state whether this well cuts through the Eocene shale and reaches the underlying sands or not. The well of the Devil's Den Consolidated Co., in section 22, T. 25 S., R. 18 E., starts in shale. It lies on the west slope of an anticline, which runs in a southeasterly direction through the shale belt south of Dagany Gap. The structural and textural characteristics of the Eocene and middle Miocene brown shales are so similar, that without thorough paleontologic study it is impossible to differentiate them, unless by their relation to the lower Miocene (Vaqueros), which separates them stratigraphically. The massive shale running southeast from Dagany Gap

ROUND MOUNTAIN MINES AND HISTORY.

By J. P. LOFTUS.

*Round Mountain lies to the north of Goldfield 100 miles. It is an isolated hill on the east edge of Smoky valley, segregated geologically and geographically from the main range. The hill which rises 1500 ft. above the plain, is an early andesite, fissured around three-fourths of its entire base in concentric circles half way to its summit. This fissuring, due to later disturbance, follows unusually uniform lines, and represents points of original weaknesses in the mountain structure. As far as an agreement has been reached, the ore mass is an altered form of the original rock, enriched and silicified by a thermal flow from some deep seated point in the mountain. The veins dip into the hill at an angle of about 25° from the horizontal, and followed to the lowest depth yet reached, 800 ft., show no change in structure or ore character. The gold is free, unassociated with any base; the ore mass—which runs from 8 to 14 ft. thick—being highly oxidized. Sulphides appear nowhere, nor has a drop of water yet appeared in the deepest works.

Gold was first discovered at this point in February, 1906, on ground owned by Louis D. Gordon. So sensational was the find that Goldfield men trekked hurriedly across the unknown wastes and mountains, and a new camp was born. This was the beginning, and for a few months, Round Mountain showed greater promise of golden wealth than even Goldfield at its best. Slabs of virgin metal were almost daily found. Organizations by the dozen sprang into existence over night; for a time money poured in for development. The mine is now developed to a depth of 800 ft., equipped with a 100-ton mill, and has produced to date, in a period of two years, \$709,184 in gold bullion, and has paid \$192,184 in dividends.

On a bleak morning in February, 1906, sitting among the rocks, viewing a trench scarce a foot deep and ten in length, Louis Gordon agreed with J. R. Davis, for a consideration of \$87,000 to sell the control—and the hole not two feet deep! Inside of 11 months that ground was pouring out gold; in 18 months the first quarterly dividend was declared. Ore is now blocked out in the mine and cash in its treasury to a value approximating \$900,000.

The mill treats 100 tons of ore per day, yielding 93% of the ore value. It has never stopped a day nor an hour through any defect in construction. It was built at a total cost of \$40,000, and occupies an unusually small space.

The manager's report for the fiscal year closing July last, showed the average value of the ore treated to be \$13.40; the extraction, simple plate amalgamation, with no cyaniding or concentrating of any kind, to be 93%, leaving in tailing \$1.10. The cost of mining for that period was \$6 per ton, which, has by the introduction of electric power and machine-drills been lowered to \$4.17 per ton—demonstrating that \$5 ore can be mined at a profit.

Of the future of the mine no one can speak of a certainty. Adjoining ground has been acquired until now the total area of the Round Mountain Mining Co. covers 700 acres, nearly one-half of the entire mountain.

The total production of the camp may be estimated as below:

| | |
|-------------------------------|-------------|
| Round Mountain Mining Co..... | \$709,000 |
| Placers | 150,000 |
| Sphinx | 60,000 |
| Daisy | 60,000 |
| Lessees (various) | 30,000 |
| Fairview | 60,000 |
| Total | \$1,069,000 |

ROUND MOUNTAIN, NEVADA.

By F. L. RANSOME.

*A few hours were spent at Round Mountain, Nevada, on June 29, 1908, and the following notes are based upon the necessarily hasty examination possible in so short a visit. The town of Round Mountain, which contains from 500 to 600 people, is in Nye county, 45 miles (about 70 miles by road), north of Tonopah and nearly the same distance south of Austin. It lies on the east side of Big Smoky valley, at the base of the Toquima range, being 12 miles north of Manhattan and three miles southwest of the abandoned mining camp of Jefferson. Further details regarding the surroundings of the district may be had from the Tonopah topographic sheet of the United States Geological Survey, and a good general description of the camp has been published by George A. Packard.† The town takes its name from a small oval hill of rhyolite which rises about 400 ft. above the alluvial slope of the valley's edge. There is abundant water for all ordinary purposes, a supply from Shoshone creek, east of town, having been made available by an outlay of \$65,000.

The rhyolite of Round Mountain is generally fresh, with abundant phenocrysts of quartz and feldspar, up to about 5 millimeters in diameter, in a light-gray lithoidal matrix, which, as a rule, shows some flow structure. No microscopical study has been made of this rock, but it appears to be a normal rhyolite with orthoclase (sanidine), as the principal feldspar. According to Mr. Packard, granite has been found underlying the rhyolite near the saddle connecting Round Mountain with the main range east of it, and some shafts east and northeast of the hill are said to show slate and quartzite. The only mine examined during my visit was the Sunnyside, on the south slope of Round Mountain. This, the principal mine of the district, is worked through a 35° shaft to a depth of 550 ft., measured on the incline. The levels are 50 ft. apart and explore the vein for a length of about 300 ft. The general strike of the vein is nearly east and west. The orebody is fully 300 ft. long and from 6 to 20 ft. in width as measured in horizontal planes and extends from the surface to an unknown distance below the bottom level. The dip varies

*Abstract from Contributions to Economic Geology, 1908. Bulletin 380, U. S. Geological Survey.

†Round Mountain, Nevada: MINING AND SCIENTIFIC PRESS. June 13, 1908, pp. 807-809.

*Abstract from address before American Mining Congress at Goldfield, Nevada.

from 35°N. at the surface to 20°N. on the 550-ft. level.

The ore is all oxidized and carries, on an average, from \$10 to \$15 in gold to the ton. Ore worth \$25 a ton is exceptionally good. Although the deposit has been referred to as a vein, it is not really of that class. It is a mass of jointed and irregularly cracked rhyolite, somewhat stained with iron oxide, but showing no conspicuous alteration and no evidence of extensive movement. In most places the ore is separated from the country rock of the hanging wall by a close fissure or joint, the difference between ore and waste being not, as a rule, evident to the eye. Such a joint, when followed along the strike, is found to pass at some point into the ore or into the country rock, and another one of slightly different strike takes its place as a working boundary to the ore. The hanging wall is thus defined by a series of joints that intersect or meet at large angles. The distinction between ore and country rock is less definite on the foot-wall side of the deposit. On the

Round Mountain, Nevada.

whole, the limits of the orebody must be determined by panning or assaying and are not certainly recognizable from structure or appearance.

The value of the ore is practically all in gold, which is readily amalgamated. The mill, equipped with 2 Nissen stamps, 2 Huntington mills, and a tube-mill, treats about 100 tons per day and extracts 92% of the gold. Some coarse gold is found, associated with limonite in crevices in the rhyolite, but in most of the ore none of the metal is visible. No pyrite was seen in any of the ore, although a little was noted disseminated in the rhyolite at one place on one of the lower levels. In 1908 the mine, according to J. P. Loftus, president of the company, was producing from \$35,000 to \$42,000 a month. Steam power is used. The fuel is wood from the Toquima National Forest, purchased at \$1.25 a cord, and cut and delivered at a total cost of \$8 to \$10 a cord.

A few hundred yards west of the Sunnyside mine some lessees have a shaft 200 ft. deep on what is probably a continuation of the same deposit. At the time of visit they were hoisting \$15 ore, which was hauled to a mill near town and there treated at a total cost of \$7 per ton. West of this lease, near the west end of the hill, is the Sphinx mine, 200 ft. deep, and probably also on the same zone of mineralization. The ore at the time of visit was similar to that of the Sunnyside mine but of lower grade, the average value being a little less than \$10 per ton. About 25 tons per day are treated in a Huntington milling plant

with no stamps. The Fairview and Daisy mines, east of Round Mountain, were producing in 1908, but were not visited. Their ore is said to lie in rhyolite and to be similar in general character to that of the Sunnyside. The Fairview has a 20-ton mill on Shoshone creek, a mile northeast of town.

A notable feature of the south slope of Round Mountain is the wide distribution of the gold. Along the whole south base of the hill the superficial detritus or wash carries gold. This material, which consists of angular fragments of rhyolite of all sizes up to a few feet in diameter, with more or less earth and sand, has a maximum thickness of about 10 ft. It shows only traces of rough stratification and has accumulated by general creep down the slope accelerated by occasional heavy rains. At the base of the hill the deposit thickens and merges with the general wash of Great Smoky valley. Hydraulic operations are confined to the hill, where the bed-rock is within reach and where there is sufficient fall for sluicing. The gold is distributed through the deposit from top to bottom. When the rhyolitic bed-rock is exposed it is found to be covered in many places with a firm crust of buff-colored carbonate up to an inch in thickness. This adheres strongly to the fresh surface of the rhyolite as a rough, travertine-like crust and in places carries enough gold to make its removal by blasting profitable, especially as considerable gold is carried also in the superficial cracks of the rhyolite. Two monitors were playing in June, 1908, and the washing, according to Mr. Loftus, was yielding about \$20,000 a month. The water, however, was getting rather low and it was not possible to keep both streams in continuous operation. Prior to the use of water, gold to the value of \$39,128 was obtained with two dry-washing machines. The ground worked by this method is said to have averaged over \$5 per yard.† The gold is generally rather fine, but some nuggets of fair size have been found. A large part of the rhyolite on the south side of Round Mountain, both under the wash and higher up the slope, contains considerable gold, partly in visible joints or small fissures, and partly in rock which is not noticeably fractured. Where the joints are close together and the rhyolite between them rather soft and decomposed, assays as high as \$250 per ton are said to have been obtained from samples taken near the surface; and from solid blocks of unfissured rhyolite assays up to \$4 per ton are reported. How far this gold represents mere superficial enrichment is still an unsolved problem. In 1908 prospecting was in progress to determine whether or not extensive masses of rhyolite on the south side of the hill can be worked by an open-cut method for the gold scattered through the rock.

Aluminum is used in constantly increasing quantities in the motor-car industry, combining both lightness and stiffness. It is used in making crank-cases, gear-boxes, carburettors, radiators, dash-boards, and in smaller ways. In castings it has been found advantageous to alloy the metal with copper, zinc, or nickel, which increases its strength and makes it easier to work.

†Packard, G. A., *op. cit.*, p. 809.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Mining locations may legally overlap previously acquired territory held by others, whether patented or unpatented or whether held under agricultural or mineral laws or whether the inclusion is due to accident or design or with the consent of the owner, or without, if peaceably done.

Charcoal from nut-pine (piñón) which grows abundantly over the mountains of the semi-arid Southwest, is of excellent quality if well burned. For lead-smelting it would make a satisfactory fuel, but it would be advisable to burn it for that purpose in kilns rather than in open heaps.

Four-stamp batteries are so rare that no recognized practice can be stated concerning the order of drop, but as the order is intended to maintain as uniform a distribution of rock and pulp in the mortar as possible it is manifest that such a result should be obtained by dropping in the order 3-1-4-2.

The mere doing of assessment work upon a claim held without 'discovery' will not prevent adverse relocation. Marking the boundaries, coupled with actual possession and the continuous exploitation or prospecting of the ground, in good faith, will generally hold a claim against all the world without discovery.

Limit of accuracy in gold assaying is probably reached by the work done at the Philadelphia and the Utrecht mints a couple of years ago on proof-gold. Samples were exchanged for comparison by the two mints, and the Utrecht 'proof' was found to be slightly purer, the difference between the two being 0.00002 in fineness.

Iron in lead smelting performs three functions. It supplies a base for the silica present; it is reduced from the oxide in the flux by carbon, or carbon monoxide, and the metallic iron so produced directly replaces the lead in PbS, the result of the re-action being metallic lead, ferrous sulphide (FeS) and CO₂. Finally it substitutes itself in the place of lead oxide in the lead silicate formed in the blast-furnace, after which the PbO is reduced by carbon.

Bullion sample-bars are not as accurate as discs. The molten metal may be poured into a shallow circular iron mold. With a power-cutter, or even with a chisel, a sector may be taken from this disc, like a piece of pie. The tendency to segregation of gold and silver on cooling is well known. This method of sampling overcomes the irregularity which would result therefrom, and which interferes with accuracy in testing a rectangular bar. This method is also more accurate than granulating by pouring in water.

Sand for concrete should contain not over 0.1% organic matter. If it exceed that figure the tensile strength of the concrete will be lessened. The safest rule is probably that of the American Society of

Civil Engineers' Committee on Concrete and Reinforced Concrete, as follows: "Mortars composed of 1 part portland cement and 3 parts fine aggregate by weight, when made into briquettes should show a tensile strength of at least 70% of the strength of 1 to 3 mortar of the same consistence made with the same cement and standard Ottawa sand."

Pitch of a thread is the distance from centre to centre of two adjacent threads. It is the reciprocal of the number of threads per inch. For example, if the number of threads be 16 per inch, then the

$$\text{pitch} = \frac{1}{16} = 0.0625 \text{ inch.}$$

The 'lead' of a screw-thread is the distance the screw will travel forward when given one complete revolution. For a single-threaded screw the pitch and lead are equal, but if a screw be provided with a double thread then the lead is equal to two times the pitch.

Puddle is a mixture of gravel and clay, wetted, and rammed into place. The gravel is used to insure the crumbling of the sides and roof of any incipient hole which may occur in the puddle-wall, causing it to fill up. A good proportion for the ingredients of an impermeable puddle-wall, according to John T. Fanning, is: Coarse gravel, 1 cu. yd.; fine gravel, 0.35; sand, 0.15; and clay, 0.20. This, when mixed will make 1.3 cu. yd., and upon ramming reduces to 1.25 cu. yd. Another mixture, which will make 1.1 cu. yd., on ramming, is gravel 1 cu. yd., sand 0.35, and clay 0.25. Puddle may be used as the core of an earthen dam; also as an impervious lining for reservoirs.

Cones used for testing temperatures in clay burning vary as to fusing point with composition. The fusing points of the cones most used are given below:

| Cone Number. | Fusing point. | |
|--------------|---------------|---------|
| | Deg. C. | Deg. F. |
| 0.022..... | 590 | 1094 |
| 0.015..... | 800 | 1472 |
| 0.010..... | 950 | 1742 |
| 0.050..... | 1050 | 1922 |
| 1.000..... | 1150 | 2102 |
| 5.000..... | 1230 | 2246 |
| 10.000..... | 1330 | 2426 |
| 15.000..... | 1430 | 2606 |
| 20.000..... | 1530 | 2786 |
| 25.000..... | 1630 | 2966 |
| 30.000..... | 1730 | 3146 |
| 36.000..... | 1850 | 3362 |

Natural asphalt imported from Trinidad and Bermudez supplies a large part of the paving material used in the United States. Oil asphalt, when properly made in the process of distillation of asphaltic oils, is free from earthy substances commonly carried by natural asphalt, and, though hampered by freight charges, is brought to the Eastern markets in large quantities. Bituminous rock is used chiefly for paving. The other important uses of asphalt products are in waterproofing metals, papers, and fabrics, in roofing, electric installations, wood preservation, brick and wood block filling, concrete construction, coal briquetting, adulterating hard rubber, and the like. Gilsonite and grahamite are also especially adaptable for use in the manufacture of japans, paints, and varnishes.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

MINING LEASE—SIGNIFICANCE OF 'CREVICE' OR 'RANGE'.

The word 'range' as applied to mineral deposits is commonly understood to designate a large stretch of country, often many miles in length and of considerable width, carrying with some continuity, or at intervals, ore deposits belonging generally to the same geological stratum. A 'crevice' is a word sometimes applied to a mineral-bearing vein; but under the Wisconsin statute the words 'crevice' or 'range' had a local significance, limiting the word 'range' by its associated word 'crevice', and taken together they were not intended to designate a large stretch of country carrying with some continuity, or at intervals, ore deposits and belonging generally to the same geological stratum.

St. Anthony Min. & Milling Co. v. Shaffra (Wis.) 129 N. W. 238, March, '09.

LOCATION NOTICE.

Under a statute providing that the locator of a mining claim should post his notice of location at the point of discovery, a locator posted his notice at a different place, but thereafter posted it at the point of discovery, and in an action by a conflicting claimant, and as against his intervening rights, the location of the original locator was postponed to the date when he posted the notice at the point of discovery, as the statute required. And where the location notice described the vein as north and south, it was held sufficient to support a location of a claim along a vein east and west.

Butte Northern Copper Co. v. Radmilovich (Mont.) 101 Pac. 1078, May, '09.

LEASE OF MINE—DISCOVERY—REVOCATION.

A miner operating under a license from a lessor, terminable at his will, in case of the discovery of a prospect, may continue his exploration free from the lessor's right to revoke the lease before the prospect has been sufficiently explored to determine whether it will lead to a discovery or not, and in case of a discovered vein or crevice, to entitle the miner to follow the deposit within the lines of the leased premises lengthwise, sidewise, and downward, on paying the current royalty to the lessor.

St. Anthony Min. & Milling Co. v. Shaffra (Wis.) 129 N. W. 238, March, '09.

MINING—DISCOVERY.

The development and uncovering of a mineral deposit in a known mineral-bearing lode and along side of old workings which existed long prior to the inception of the lease, did not constitute 'discovery' within the meaning of a statute which provided that the discovery of a crevice or range containing ores should entitle the discoverer to follow it until it was exhausted free from the right of the landlord to forfeit the lease.

St. Anthony Min. & Milling Co. v. Shaffra (Wis.) 129 N. W. 238, March, '09.

APPLICATION OF STATUTES TO MINING.

The statute of Wisconsin regulating mining was held by the Supreme Court of that State to apply only to mining contracts and leases either oral or written for the digging of ore and minerals, when there was no contract between the parties contrary to the statutes and where there were no terms established by the landlord contrary to its provisions.

St. Anthony Min. & Milling Co. v. Shaffra (Wis.) 129 N. W. 238, March, '09.

SINKING DISCOVERY SHAFT.

A locator is not required under the statute of Montana to sink his discovery shaft at the point of discovery.

Butte Northern Copper Co. v. Radmilovich (Mont.) 101 Pac. 1078, May, '09.

Publications Received.

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

DEVELOPMENT OF A NEW WESTERN TERRITORY. By W. W. Weston. Bankers Magazine, August, 1909.

Construction of railways as a means of opening territory has been a characteristic method of development in Western States. Mr. Weston tells, in this article, how it is being done in the case of the Denver, Northwestern & Pacific railroad which D. H. Moffat is now building into northwestern Colorado. The region has much of interest to mining men and in the opinion of Mr. Weston is not only destined to be a great farming and fruit raising country, but a mining country as well. It contains the hydro-carbon field of Uinta county, Utah, with veins of gilsonite, the available tonnage of which has been estimated by the engineers of the United States Geological Survey at 32,000,000; and as this product is worth \$30 per ton, a vast potential wealth is represented. There are also many veins of elaterite and ozocerite, which products are still more valuable, and reefs, miles in extent, of sandstone asphaltum, which will be rendered available to commerce by the advent of the road. Among other undeveloped hydro-carbon products in this valley are also oil and vast areas of bituminous shales.

NOTES ON PRACTICAL MECHANICAL DRAWING. Written for the use of students in engineering courses by Victor T. Wilson and Carlos L. McMaster. 3d ed., revised and enlarged. Published by the authors at East Lansing, Michigan, 1909. Price, \$1.50.

This useful little volume has a field of its own. Insistence is not made on geometrical drawing, but the principles are largely illustrated by the use of actual problems, such as arise in practice, from the very beginning. It deals with orthographic projection, isometric and oblique drawings, use of instruments, working drawings, machine sketching, and contains a good description of blue-print processes and reproduction.

CHROME IRON ORE DEPOSITS. By Fritz Cirkel. Canada, Department of Mines, Mines Branch, No. 29. Pp. 141. Ottawa, 1909.

An illustrated account of the occurrence of the ores in the Eastern townships of the Province of Quebec.

Catalogues Received.

BLAISDELL Co., Pacific Electric Bldg., Los Angeles, California. Catalogue L, 'The Blaisdell Patent Vacuum Filter Leaf'. 4 pages. Illustrated. 6 by 9½ inches.

JOSEPH DIXON CRUCIBLE Co., Jersey City, New Jersey. 'Dixon's Foundry Facings'. Information on the proper use of facings; a list of the different kinds carried, including prices. 12 pages. 3¼ by 6¼ inches.

THE PARAFFINE PAINT Co., 34 First St., San Francisco. Booklet of views showing buildings of the Alaska-Yukon-Pacific Exposition, illustrating the general use of Malthoid Roofing. 32 pages. 3½ by 5¼ inches.

DEARBORN DRUG & CHEMICAL WORKS. Postal Telegraph Bldg., Chicago, 'Water Treatment.' An elaborate pamphlet giving some historical facts about the firm issuing it, and the work which it is doing. Illustrated. 10½ by 8 inches.

BAUSCH & LOMB OPTICAL Co., Rochester, New York. 'Unique Features of Bausch & Lomb Engineering Instruments'. A folding leaflet giving some information as to the engineer's instruments manufactured by this well known firm. 8 pages. 3 by 6 inches.

FAIRBANKS, MORSE & Co., Chicago, have issued a new catalogue (No. 80 D) describing their small engines from 1 to 12 hp., in which they describe for the first time the new 1-hp. engine 'Jack Junior'. This is a practical, durable 4-cycle engine, water-cooled, and is made to meet the demand for a small reliable engine for running light machinery. The catalogue describes the principles of operation and construction of their gasoline engines and is full of engineering suggestions stated in plain language for the benefit of engine users.

Five Hundred Horse-Power Electric Mining Hoist.

There was recently installed in the mine of the Washington Coal & Coke Co. at Dawson, Pa., by the Westinghouse Electric & Mfg. Co., a large mine-hoist with a motor presenting several features of interest. The hoist is used to haul 35 mine-cars, averaging 3800 lb. each when loaded, up a maximum grade of $8\frac{1}{2}\%$, 8000 ft. long, at a speed of 600 ft. per minute. The loaded cars start at the bottom of the slope on a 4% grade, which gradually increases until the maximum grade of $8\frac{1}{2}\%$ is reached near the top, where the loaded cars are pulled in on a landing on a grade of about 6%, and on a curve of 150 ft. radius. The empty cars will be allowed to run down the slope by gravity, controlled by a brake on the hoist-drum.

The drum itself is 6 ft. diam. and 5 ft. wide between flanges. It is fitted with a hand-brake on one end, and a hand-operated friction clutch on the other end. The drum is of heavy steel construction, with a 12-in. shaft. All the gears on the machine are cast-steel with machine-cut teeth, the main spur-gear being 10-in. face and the motor-gears 13-in. face. The frame is made in sections for convenience

in installing in the mine. The drum, large gears, and the friction clutch parts are also made in two pieces for the same purpose.

The hoist is driven through a flexible coupling by a 500-hp., direct-current, non-reversing, compound-wound Westinghouse motor. It is controlled by a standard semi-automatic Westinghouse magnetically-controlled unit-switch controller. These switches are operated from the controller shown in the illustration, the controller carrying only small currents, while the main motor-current is handled by the magnetically-operated switches, thus doing away with the difficulties from arching.

This controller has an accelerating relay which prevents the starting switches from closing too rapidly, and thereby prevents too large starting-currents. Thus the second switch cannot close until the current allowed to flow by the closing of the circuit has fallen to a pre-determined value. As soon as this value is reached the second switch closes, thereby short-circuiting a resistance section, and the current rises, but the third switch cannot close until the current has again fallen to the pre-determined value. This not only prevents injury to the motor from careless handling during acceleration, but also insures the most rapid starting possible. The controller also has a safety-relay which opens the resistance switches in cases of excessive overload, and thereby protects the motor while running. If this relay operates while the motor is running, the motor does not stop, but is automatically brought up to its full speed again. This is a particularly valuable feature in an installation of this kind where the cars may strike some obstruction, as it affords

perfect protection to the apparatus. When it is remembered that this hoist is installed some 800 ft. below the surface of the ground, the advantages of the electric transmission of power are evident. In no other way could this large amount of power be transmitted as economically nor as easily.

Commercial Paragraphs.

The Alaska-Yukon-Pacific Exposition has awarded grand prizes (highest award) for insulated wires and cables to the GENERAL ELECTRIC Co. and the JOHN A. ROEBLING SONS COMPANY.

THE KELLY FILTER PRESS Co., Salt Lake City, recently installed one of its presses in each of the following mills: Gold Issue M. & M. Co., Cripple Creek, Colorado; Alaska Treadwell Gold M. Co., Treadwell, Alaska; Enterprise M. Co., Cooney, New Mexico.

The SMOOTH-ON MFG. Co., Jersey City, New Jersey, has just published the eighth edition of its instruction book. It is fully illustrated and shows many of the different ways in which Smooth-On cements may be used. It will be sent free to any address.

WEED & PROBERT is the name under which Walter Harvey Weed and Frank Holman Probert have formed a partnership for practice as geological and mining engineers. Offices will be maintained at 42 Broadway, New York, and at the Central Bdg., Los Angeles, California.

The UNION IRON WORKS Co., San Francisco, has lately received an order from the South Eureka Mining Co., Sutter Creek, California, for a 20-stamp mill. It is worthy of note that the machine-shop and foundry of the Union Iron Works is running at full capacity.

ELI T. CONNER has opened an office as Consulting Mining Engineer at 1126 Real Estate Bdg., Philadelphia. He has had an experience of more than 25 years in the operation of anthracite

and bituminous properties, and makes a specialty of examinations for prospective purchasers, investors, banks, and trust companies, and with a view to suggesting betterments and improvements.

THE C. O. BARTLETT & SNOW Co., Cleveland, report the following recent orders: Kelley Island Lime & Transport Co., Cleveland, Ohio, one elevator, capacity 1000 tons of crushed stone per hour; and one elevator, capacity 600 tons of crushed stone per hour, said to be the largest elevators of the kind ever constructed; Winding Gulf Colliery Co., Cincinnati, Ohio, Greene self-dumping car-haul and complete outfit, capacity 2500 tons of coal per eight hours; William A. Clark, Butte, Montana, one ore dryer; American Smelters Securities Co., New York City, one ore dryer for mines at Santa Barbara, Chihuahua, Mexico.

Mineral Areas in Korea.

According to Thomas Sammons, Consul-General at Seoul, the Government authorities place the number of localities in Korea suitable for mining at 184, as follows: gold mines, 53; silver, 5; copper, 25; iron, 36; lead, 2; graphite, 34; zinc, 2; coal, 21; petroleum, 5; and mercury mines, 1. Aside from 7 gold mines, 2 copper properties, a number of iron prospects, two or three graphite mines, and a couple of coal deposits, the mineral resources of the kingdom are undeveloped and largely unproductive. A large number of claims have been filed, but the holders of mineral areas in Korea are, as a rule, unprepared financially to develop.

EDITORIAL.

AN aerial navy is being developed near Washington, doubtless to prevent competitors flying over our tariff wall.

PRODUCTION of copper at Cerro de Pasco, Peru, amounts to 4,000,000 pounds per month, and arrangements are being made to increase the output within a year to 60,000,000 pounds per annum.

ERRORS of fact by telegraphic correspondents led to our misrepresentation of President Zelaya. He was not as indiscreet as we were led to think; he was not at Cape Gracias á Dios; he is very decidedly at the nerve-centre of his caliphate, and will not be easily beaten.

SIXTY YEARS is a long period in the life of a trade journal, and we extend congratulations to the *Iron and Steel Trades Journal*, on its long career of usefulness. Its diamond jubilee issue is fittingly devoted mainly to retrospect, but room has been found none the less for a few cheerful words as to the future. "We shall continue to do our part to produce a good, reliable journal. We shall continue to express our honest convictions, even as regards the operations of multi-millionaire concerns, without fear or favor." Good. Such are the ideals of the best technical journals of today, and, we are glad to add, of the most successful ones. May our contemporary celebrate many more anniversaries!

STEALING ore is almost as safe and respectable as stealing railways. Occasionally, however, accidents will happen as at Manhattan, Nevada, recently when 'high-graders' in the Stray Dog mine found it necessary to shoot an unaccommodating Deputy Sheriff in order to get away with their booty. At Goldfield on the same day a man accused of having taken part in stealing concentrate valued at \$21,000, by means of a diverting device in the Consolidated mill, was discharged for lack of evidence. Ore thieves, so long as they confine their stealing to the mines, really have little to fear from American juries, owing partly to the elaborate legal doctrine argued at Cripple Creek that ore in place in the mine is real estate, and hence can not be stolen. This is small comfort, of course, to the manager who sees his receipts decrease in inverse ratio to the richness of the ore, but it gives solace to the accused.

COPPER production in the United States today amounts to 1,400,000,000 pounds per annum. The Cole-Ryan-Amalgamated group is responsible for 30 per cent of this amount, and the Guggenheims for 15 per cent. Following these are Phelps, Dodge & Company, Calumet & Hecla, American Metal, and L. Vogelstein & Company. The policy of the Guggen-

heims has been to produce and to accept ore from shippers without limitation, and until lately to sell copper rapidly, without regard to metal-sellers' agreements. As the Guggenheims have controlled supplies that could be produced more cheaply than the Cole-Ryan capitalists, they have been a disturbing element in the market. The latter restricted production for a period, as did Phelps, Dodge & Company. The output now is nearly normal. The attitude of Calumet & Hecla has been, as ever, loftily independent, but rational and conservative. Securely fortified by low costs unapproachable by rivals, it could undersell them and depress the market further, but instead of sacrificing ore reserves in that manner it has voluntarily curtailed its production about one seventh. Strong efforts are being made through J. P. Morgan & Company to effect a combination of copper interests to regulate output and prices. This manifestly cannot be done while so many important producers, such as Calumet & Hecla and the Guggenheims, are able to turn out copper at low prices. The Guggenheims will be strengthened by the output from the Braden copper mine in Chile, and the Cerro de Pasco will be a steadily growing factor with 5-cent copper. It will be as impossible under such conditions to effect a consolidation as it has proved for the United States Steel Corporation to absorb even 50 per cent of the steel-capacity of the country; but one powerful group, such as the Cole-Ryan, by its preponderating influence can and must serve as a regulator, with whom the others will co-operate within the limits of individual advantage.

Sludge Abatement.

Australia and New Zealand are becoming proving grounds for new methods of legislation and public administration. For the world at large they perform much the same useful function as does Oklahoma for her sister States. To say that they are socialistic requires special definition of that much abused word. But they do resort more readily than the rest of us to Government agencies to restrain individual and corporate activities. If other States and Nations are wise much useless experimental legislation may be avoided.

California has had its full quota of débris and anti-débris legislation. A great industry, that of hydraulic mining, has been practically killed by legislation to protect the agricultural lands of the Sacramento valley. Recently there has been agitation against dredging, and the question has been raised as to the extent, if any, to which dredging pollutes the streams. Not improbably in time, here as elsewhere, there will be agitation against turning into streams waste cyanide solutions and even ordinary mill-tailing. There can be no question that as population increases in density in America, the whole problem of stream pollution will come up repeatedly, and legislatures and courts will be called on to work out the necessary compromise between the ideal clear stream immediately available for drinking and the 'common sewer' plan of making streams dumping places of all the waste and filth of civilization.

In Australia some provision for study and abatement of these nuisances has been made in the creation

of Sludge Abatement Boards. The reports of the Victoria Board for 1907 and 1908 are recently at hand and offer material of particular interest. The method of work of this Board is not unlike that of the Interstate Commerce Commission; that is, complaints of nuisances as received, are investigated by special agents, followed if need be by public hearings, and finally, if the evidence justifies, by an order for its abatement. It is interesting to see that much the same complaints are made in Victoria as were ventilated this summer at Sacramento, and that there, as here, careful investigation shows them to be essentially groundless. For example in one case of alleged damage due to dredging, the Board finds: "When a bucket dredge was working a few years since in the bed of the Goulburn, some miles below Jamieson, settlers down stream were unaware of its presence. We have found that local complaints * * * are principally due to gravitation sluicing claims in the hills and to erosion of drains and creek banks." The importance of sedimentation due to erosion of ditches, roadways, and to other disturbance of natural conditions due to public works, is especially emphasized. In one case a complaining town was shown by the testimony of its own engineer to have furnished in this way to the stream more detritus than the whole possible from the mining of which complaint was made. The Board further says: "Beyond what might reasonably be expected from natural denudation and erosion in a large stream, subject to such varying volumes of discharge as the Goulburn, the evidence and observations disclose no abnormal siltation of the river flats," and further: "Some of the farming witnesses object to all discoloration, and apparently would not be satisfied in summer time with water almost clear, though compelled even where there is no mining to use worse water during winter and spring. The Board cannot recommend the extinction of a valuable industry on account of ill-grounded objections of persons not acquainted with the nature of the work, many of whom would not, owing to distance from the mines, be subject even to discoloration of water by their operations." Such a principle is sound, and its enunciation gives confidence that in the cases where the Board has ordered that tailing be impounded, real reason for the order exists.

Not less interesting are the findings of the Board in several cases involving the turning into the streams of waste cyanide solutions. It is not unnatural that some apprehension should exist among people living below a cyanide plant and dependent upon the stream for water for themselves or their stock. Two samples were taken from water courses immediately below cyanide works at Bendigo and the analyst found: "No cyanide of potassium present in the liquid. There is no chemical ingredient injurious to vegetation in any of the above samples." This accords with our own experience in catching fine mountain trout within a few yards of the discharge of a cyanide mill. The whole work of the Board seems to indicate that when these problems are intelligently and honestly studied the amount of damage is neither so large nor the means of abatement so difficult as to cause serious uneasiness.

Geological Survey Estimates.

The estimates of the Director of the Geological Survey for the fiscal year beginning July 1, 1910, have been made and approved by the Secretary of the Interior. In notable contrast with other Bureau estimates for the year they provide for increases in appropriation for geology, study of Alaskan mineral resources, study of water resources, and study of structural materials. That the Director should make, and the Secretary approve, estimates involving increases, in the face of direct intimations from the President to the effect that all estimates were to be decreased, is strong presumptive evidence of the need of the money. It is also flattering recognition of the importance of the mineral industry. We propose to examine these estimates individually, taking first the sum requested for additional geological studies.

The United States Geological Survey began its work in 1879 with a total appropriation of \$100,000 to cover all its activities. It is only a few years since the amount available was scarcely a half million dollars. For the current year the money devoted to this branch of the public service amounted to one and three-quarters million dollars or, deducting money spent for rent and expense of printing, which is not administered by the Director, the total was \$1,497,390. Of this sum \$225,000 was for the geology, to which also a portion of the money for statutory and temporary salaries was applied. In all probability \$250,000 or more was available for geologic work within the United States.

It is evident from this increase in appropriations that the work and conduct of the Survey has commended itself both to the public and to Congress. The Survey is everywhere recognized as one of the cleanest and most efficient bureaus in the public service. Its career has been long and honorable and its usefulness is universally recognized. The intimate relations between geology and ore deposits have always led mining men to look upon the Survey as belonging peculiarly to them, and in certain circles there has been some not unnatural jealousy over the large amount of money and attention recently devoted to subjects not immediately related to mining. We are apt at times to forget that geology is one of the sciences that has numerous relations—to agriculture, to forestry, and to general engineering—and that a public service bureau has responsibilities in all directions in which it can be useful. Nevertheless it may be fairly urged that work in the Western metalliferous districts, if not actually curtailed, has decreased in amount and importance in comparison with the newer activities of the Survey. A few years ago Emmons, Becker, Spurr, Lindgren, Ransome, Weed, Boutwell, Irving, and a brilliant group of younger men, were simultaneously working on Western ore deposits. Of these, except Ransome, no one continues to devote his major attention to such work for the Survey. The lure of private work, the burden of administration, or the attraction of other problems, has drawn each away, and the group of younger men who were coming up to take their places is mainly scattered and gone. It cannot be urged that the problems of ore deposition are less in-

teresting or less important than in earlier years. It is true that detailed geological and structural maps of many districts are now available, that the problems of ore genesis are somewhat better understood, and that the discovery of the laws of secondary enrichment has made prospecting of the porphyry copper ores, especially, much more certain. The rapid exploration, however, of the areas capable of being prospected by mere sampling of outcrops, has made more study and the scientific direction of prospecting necessary. The smelting industry of Colorado is today in unstable equilibrium because of lack of suitable silicious ores; and Colorado has been prospected and re-prospected by the old methods. Yet it would be a hardy prophet who would affirm the absence of the very ores needed. There remain also many camps which are still unsurveyed and others demand re-survey and re-study. The Geological Survey should be increasing its activities in the metal-mining districts instead of decreasing them. It needs more men, more money, and new methods. It must do its part, which doubtless will be large, in developing scientific prospecting, just as the Department of Agriculture has developed scientific farming. The United States Government is still, probably, the largest owner of mineral lands, and it is probable that it will ultimately become necessary to prospect them before sale, adding the cost of prospecting to the sale price, much as the Reclamation Service puts water on desert land and then sells the latter at an increased price. The difficulties in the way of such work are numerous and its need is not immediate, but these are all the stronger reasons for looking to the future and being ready for the task when it comes.

The reason why the Survey-work in the Western metalliferous regions has not been vigorously pushed recently, lies in its increased burden in connection with the classification of public lands, especially those containing coal. The importance of these classification surveys cannot be denied, but they should not be pushed at the expense of equally necessary studies of other lands. Mr. James A. Tawney, Chairman of the House Committee on Appropriations, was right when he insisted on the Survey taking up this long-neglected burden; but work of such importance demands special funds instead of incidental provision from existing appropriations. It is well to be economical, but true economy dictates liberal support for those agencies which develop wealth.

In the plans for the coming year \$25,000 additional is estimated for geology, and it is understood that this is to allow the Survey to expand its work in the Western metalliferous districts. The sum is small in proportion to the work, but should make possible some additional parties as well as such increases in salaries as will at least delay the loss of good men to outside interests. A much larger sum should be available, but any experienced administrator will recognize, albeit at times regretfully, the need of making haste slowly in increasing expenditures on any work. Large and sudden increases provoke poor administration and waste, but we will hope that the sum asked for will not only be promptly granted, but be merely the earnest of annual increases so long as the needs of the work demand them.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

W. S. NOYES is in Oregon.
J. H. CURLE is on his way to Bokhara.
K. T. LEWIS has gone to Rawhide, Nevada.
FRANK W. GRAHAM, of Denver, is in London.
FRANK H. PROBERT is at Guanajuato, Mexico.
H. COLLEBRAN is in London on a visit from Korea.
VICTOR BRASCHI, of Mexico City, is at New York.
E. M. HAMILTON is at Ventañas, Durango, Mexico.
W. H. SHOCKLEY has returned to London from Siberia.
E. T. MCCARTHY has returned to London from Siberia.
GENARO ESCOBOSA has returned to San Días, Mexico.
N. SAMWELL, of Rangoon, Burma, is in San Francisco.
C. S. HERZIG was at Rawhide, Nevada, and has gone to Ely.

J. E. SPURR is examining mines in the State of Washington.

F. LYNWOOD GARRISON has returned to Philadelphia from Mexico.

S. E. BOLT is with the Arizona United M. Co., at Johnson, Arizona.

HENRY HAY left London on October 9, returning to Johannesburg.

P. C. JURS, of the Union Iron Works, was in Los Angeles last week.

LESLIE URQUHART is manager of the Kishtim copper mines, in Siberia.

H. C. HOOVER has returned to London from a flying trip to New York.

THEODORE J. HOOVER is at the Caucasus Copper Co.'s mines in Asia Minor.

W. E. THORNE is examining placer properties near Gold Creek, Montana.

GEORGE A. SCHROTER, of Denver, is at New York on professional business.

FREDEBICK A. KAUFMAN, of the United States of Colombia, S. A., is at New York.

GEORGE MACFARLANE represents Bewick, Moreing & Co. at Tarkwa, West Africa.

E. G. SPILSBURY is investigating Tonopah and vicinity for a New York syndicate.

ROBERT ALLEN has returned from Parral, Mexico, and will proceed at once to Johannesburg.

AUGUST MATHEZ, of Denver and Salt Lake, has opened an office at 42 Broadway, New York.

F. W. OLDFIELD is returning from Hostotipaquillo, Jalisco, Mexico, to Los Angeles, California.

ROBERT SMART, government assayer at White Horse, Yukon Territory, was in Seattle last week.

JAMES H. FOX, of Seattle, was recently examining properties in the vicinity of Baker City, Oregon.

WALTER G. PERKINS is expected in London on his return from the Tanganyika Concessions, in Central Africa.

F. CUSHING MOORE, mine inspector for Idaho, recently visited the active mines of Lemhi and Custer counties.

A. L. GLOVER has charge of the assay office and laboratory of the Oregon-Idaho Investment Co. at Baker City, Oregon.

I. F. LAUCKS, of Falkenburg & Laucks, Seattle, made an examination of mining properties in Chelan county, Washington.

HERBERT A. MEGRAW has taken the management of the Santa Elena mine, at San Luis de la Paz, Guanajuato, Mexico.

F. A. ROSS, late manager for the Daly Reduction Co., Ltd., Hedley, British Columbia, has gone to Hostotipaquillo, Jalisco, Mexico, in the interests of the Marcus Daly estate, which has the well known Cinco Minas under option.

General Mining News.

ARIZONA.

MARICOPA COUNTY.

A. J. Kellis and N. McCarver have located five claims covering a deposit of manganese 30 miles south of Wickenburg. The outcrop has been traced for 3000 ft., and samples taken near the surface assayed from 35 to 60% MnO_2 .—The St. Francis Mines Co. has installed a 25-hp. Fairbanks-Morse hoist at its property in the Wickenburg district. Living quarters for the men and the surface plant have been completed and considerable development is planned for the near future. George Morgan is superintendent.—The spur from Bouse to Swansea is completed to within a few miles of the town. The smelter of the Clara Consolidated at the latter place has been completed and will be blown-in as soon as the line is ready to carry freight.

MOHAVE COUNTY.

Operations have been resumed at the Neal property at Goldroad. Jacques de Salmard is in charge of the work.—A large body of milling ore has been opened on the 300-ft. level of the Southwestern Copper Co.'s mine at Copperville.—A. L. McLesson opened a shoot of rich ore on the 100-ft. level of the Holy Moses mine.—A number of samples taken from the Expansion group assayed from \$70 to \$160 per ton. The compressor has been moved from the shaft to the adit-level and the company is installing further mining equipment. C. J. Hutchison is superintendent. Mr. Hutchison and associates are to make a mill test on the ore from the property of Thomas Sickles south of Kingman with a view to obtaining a bond on the property.—At the Goldbug mine, in the Weaver district, north of Chloride, the shaft is down 500 ft. Cross-cuts are to be driven on the 400 and 500-ft. levels and drifts run on the vein.—The management is installing new electric equipment at the Tom Reed mine near Goldroad.—The electric power has been turned on at the mill of the Goldroad Mining & Milling Co., at Goldroad, and the stamps are now crushing ore. The bins are filled and a large amount of ore is piled on the dump. The management estimates that there are 400,000 tons blocked out above the 700-ft. level which has been opened for over 1000 feet.

PIMA COUNTY.

A raise is being driven in the ore from the 100 to the 60-ft. level at the Plumed Knight property in the Olive district. A stope will be opened shortly and the ore that assays over 7% copper, shipped to the smelter. L. D. Chillson is in charge of the work.—At the property of F. J. Villaescusa, in the Fresno district, on the west side of the Baboquivari mountains, a shaft has been sunk 50 ft. on a vein of free milling gold and silver ore.

PINAL COUNTY.

Operations have been resumed at the property of the Green River Copper Co., near Superior. Machinery has been ordered and will be installed at the mine within a short time. Kimball Pomery is manager.

YAVAPAI COUNTY.

H. L. Sweeney and S. H. Anderson have unwatered the 75-ft. shaft on their property six miles west of Prescott and are sinking on the vein which is 5 ft. wide.

YUMA COUNTY.

The Merry G. Mining Co. has been organized in Phoenix to open a group of claims near Winchester. A 25-ft. shaft has been sunk on the vein, samples from which have assayed \$26 gold and 106 oz. silver. J. P. Striegel is president of the company.

CALIFORNIA.

CALAVERAS COUNTY.

Frank Heath, of San Andreas, has secured the Montana mine for Eastern capitalists and will erect a 10-stamp mill on the property.—Five stamps are to be added to the Easy Bird mill.

MARIPOSA COUNTY.

(Special Correspondence).—An excellent find is reported

from the Mountain King mine near Bagby. The company has been developing the property for the last four years running the ore through a 10-stamp mill, and it is now probable that the milling capacity will be increased and a greater tonnage taken from the mine.—There are 20 stamps dropping at the Hite Cove mine, at Hite Cove, and the company plans to have 50 operating in the near future.—Considerable work is being done at the Egenhoff Brothers' property, known as the Clearing House mine, on the Merced river, and some good ore opened.—In the Hornitos district a number of old properties are being re-opened and the outlook for future mining operations is bright.

Bagby, October 25.

NEVADA COUNTY.

Operations are to be resumed at the Comlon mine, in the Grass Valley district, in the near future.—A new compressor and hoist have been installed at the Grass Valley-Dana mine which was recently taken over by the Nassau Mining Co., and the shaft is to be sunk to the 500-ft. level. Fred Godfrey is in charge of the work.—At the Kenosha

mine, near Grass Valley, the drift on the 400-ft. level opened a shoot of rich ore giving 120 ft. of backs.—The plant at the Delhi mine on the middle fork of the Yuba river near North Columbia, which was destroyed by fire last week, is to be replaced. Hamilton Eddie is superintendent.

SHASTA COUNTY.

Furnace No. 2 in the Mammoth smelter at Kennett has been shut down to install a settler similar to those at No. 3, 4, and 5. The company has commenced grading for the foundation of a bag house to eliminate the objectional fume from the smoke. The Shasta County Farmers' Protective Association delayed any legal action against the smelting companies till November 1 to give them time to find some relief from the fume, and the bag house is the result of this action.—Two miners at the Balaklala mine, at Coram, lingered in the mine after shooting and were suffocated by the powder smoke.—The well of the Bella Vista Oil Co., at Bella Vista, is down over 110 ft., and has cut a 6-in. stratum of oil-bearing sand.—The mill of the Western Exploitation Co., operating the Milkmaid mine at French gulch, is again in operation.—The drift at the Spread Eagle is in 62 ft. and the company is preparing to make a shipment to the Selby smelter.—The Appellate Court has sustained the decision of the lower courts in the Harrison gulch townsite case, giving the ground in dispute at Harrison gulch to the Victor Mining Company.

SIERRA COUNTY.

The Gibraltar gravel mine, near Downieville, has been shut down and will not be in operation till next spring.—A 9-in. vein containing considerable arsenical pyrite and free gold was opened on the Bovee property near Alleghany. At the Twenty-One mine, in the same district, a rich shoot was cut on the adit level.—The South Fork Mining Co., operating the Amethyst property, has opened a good shoot of ore in the drift from the bottom of the shaft.—The new mill, at the Chipps mine, is practically completed and will be started the early part of November.—The raise at the Omega is in gravel that runs \$5 per car.

TUOLUMNE COUNTY.

The shaft at the Trumper property is down 40 ft. on the vein.—At the Gold Spring mine, between Sonora and Jamestown, a new hoist has been installed and two machine-drills are running in the shaft which is down 60 ft. The vein is 30 ft. wide and assays from \$3 to \$18 per ton.—The new 5-stamp mill, erected by J. T. Callahan, at Big Oak Flat, is completed and will be in operation as soon as connection can be made with the power line. The mill is designed to handle the ore from the Eureka mine but will accept custom ore from the neighboring properties.—The Golden Dawn mine near Soulsbyville, owned by R. A. and John Nicholls and Thomas Webster, is to be re-opened shortly.—At the North Fork Consolidated Mines Co. property, near Arastraville, the shaft is down 50 ft. Work has been stopped temporarily on account of the power being turned off and it is probable that the company will install a gasoline power plant.—The Tuolumne Mining & Development Co. has bonded 80 acres of gravel land near Columbia and will prospect it to determine its value as a dredging property.—A diamond-drill is to be installed in the Dutch mine, at Quartz, to prospect the lower levels. Chas. H. Stregerson is in charge of the work.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—A 7-in. streak of smelting ore has been opened in the Bellmont property on Saxon mountain that assays 758 oz. silver, 0.03 oz. gold, and 62% lead.—The concentrating mill at the Wilcox adit is being run on one shift and from 80 to 90 tons of ore is being crushed per day.—At the Tobin adit 26 men are at work. There is ready for shipment over 600 tons of smelting ore that is worth from \$45 to \$50 per ton in gold, silver, and copper. Stopping is in progress and for a length of over 500 ft. a body of ore is exposed that is from 1 to 5 ft. wide. Operations are being centered principally on the Wheeling vein.—The Linn mill is now running day and night on ore from the Mineral Chief mine, on Democrat mountain. An average of 100 tons of zinc and 120 tons of lead concentrate is being sold monthly. The zinc concentrate mills 58% in zinc, while the lead contains 62.80% lead and 15 oz. silver per ton. C. E. Pughe is manager.—A meeting of the stockholders of the Georgetown M. P. & T. T. Co. was held this week at which time the capitalization was increased from \$1,000,000 to \$5,000,000. A big campaign of development is to be put under way at once.

Georgetown, October 23.

(Special Correspondence).—Extensive development is being carried forward at the holdings of the North American Mining & Smelting Co., on Donaldson mountain. Fred Nye, the manager, is opening large reserves of ore in the drift being run on the Magnolia vein, while the Donaldson drift is being driven on a body of medium-grade ore that is from 16 to 30 in. wide. Throughout the various workings of the property large bodies of ore are showing and within a short time it is hoped to have the holdings in condition whereby the output that can be made will warrant starting the furnaces of the pyrite smelter at Golden, which the company recently purchased for a consideration of \$150,000.—The Burns-Moore adit on Chicago creek is being driven steadily forward. A force of men was put to work last week in driving one of the laterals for intersecting a number of cross veins.—The Honest John M. M. & T. Co. is employing a force of men in the development of the Black Eagle mine, on Chicago mountain.—The pumps of the

Stanley mine were started this week to unwater the shaft which has been filled for the last four years. There are five miles of underground workings in the mine, all of which are filled with water. It is expected that the water will be down to the fourth level inside of 60 days, at which time men will be put to work in the various stopes. This property was one of the former heavy producers of the district, being credited with over \$1,000,000. Jas. Bowden, who was in charge during the early operations, has been re-appointed general manager.

Idaho Springs, October 23.

GILPIN COUNTY.

(Special Correspondence).—The Newhouse adit has intersected the Gibson vein, which is supposed to be an extension of the California. It is 7 ft. wide, of which 18 in. is smelting ore, and was cut at a vertical depth of 1600 ft. R. W. Miller, of Nevadaville, is manager.—Two carloads of 2-oz. gold ore were shipped last week from the Two-Forty mine, in Willis gulch, the product being delivered to the Modern smelter at Utah Junction. Hereafter the ore will be sent over the Gilpin tramway from the main shaft, as a side track has been put in to connect with the main line.—Joseph Ross & Co., leasing on the 500-ft. level of the Iron mine, on Pewabic mountain, have opened a large body of ore, both of a smelting and concentrating grade. The smelting streak is from 14 to 16 in. wide, and assays over 2 oz. gold per ton.—Shipments of both smelting and concentrating ore are being maintained from the Egyptian mine on Quartz hill. The first-class product mills \$100 gold per ton, while by reducing from four to five tons to one the concentrate is worth from \$80 to \$90 per ton.—A 4½-ft. vein was cut

Gregory-Buell Mine.

on the 1400-ft. level of the Gregory mine, 12 in. of which is smelting ore that assays 12 oz. gold and 24 oz. silver per ton, with 20% in copper.

Central City, October 25.

LAKE COUNTY.

McCarthy, Dunn & Casey have secured a lease on the Little Alice and Eliza claims, near Leadville, and will sink a shaft on the property.—Twenty-five tons of ore is being shipped from the Silent Friend mine in South Evans gulch.—A new pumping plant has been installed at the Blanche mine and sinking resumed.—The shaft at the Highland Mary, on Breece hill, is down 100 ft. and drifts started on the vein.—The winze in the St. Louis tunnel is down 100 ft. and will be sunk to the 250-ft. level. The vein is now 3½ ft. wide and assays \$40 per ton.

OURAY COUNTY.

The winze on the lowest level of the Frank Hough mine in the Ouray district opened a body of rich copper ore.—A drift is being driven from the raise at the Thistledown property to get under the face of the adit, where a connection will be made with the latter.—Living quarters have been erected at the Free Gold group, in Poughkeepsie gulch, and work will be continued all winter.—The management of the Treasury tunnel at Red mountain, which has now been driven over a mile, has laid in supplies for the winter and is raising on one of the shoots cut near the face of the tunnel.—At the Atlas mine the drift to connect the Atlas and San Pedro workings is the main development and is furnishing ore to keep the mill running steadily.

SAN JUAN COUNTY.

The Hercules Consolidated Mining Co. has resumed operations at its property on Sultan mountain at Silverton.—A carload of high-grade ore has been sacked for shipment at the Shamrock group above Animas Forks.—Twenty cars of rich copper ore was shipped to the smelter from the Highland Mary near Silverton.—A force of nine men is working at the Gold Bug mine of the Syndicate Gold Mining Co., in the western part of the county. The company recently shipped four cars to the smelter at Durango. Martin Tulley is manager.—The mill and tramway at the Gold King mine, near Gladstone, have been repaired and the mill is running night and day. The company has erected new dwelling quarters for the men at the mine and an office in Gladstone.—At the Gold King Extension an adit is being driven that will open the vein at a depth of 1000 feet.

SUMMIT COUNTY.

T. E. Shaw has secured a contract to erect a \$126,000 hydraulic plant at the property of the Buffalo Placer Mining & Milling Co., near Dillon. There are 1840 acres in the property which is in charge of Lemuel Kingsbury.—A contract has been let for 500 ft. of cross-cutting at the Excelsior mine.—A contract has been awarded to drive the Mary Verna tunnel 500 ft. The present face is 3400 ft. from the portal.—The mill at the White Cloud is running on a good grade ore from the mine. A. A. Pike is superintendent.

TELLER COUNTY.

By the payment of \$45,000 Allen L. Burris completed the payment of an option on 72,500 shares of the El Paso Consolidated Gold Mining Co. of which he is president. The option price of the stock was 80c. per share and 20c. of this had been paid upon the taking of the option.—The Colorado Mines Investment Co. has resumed operations at the American Eagles mine on Bull hill, and has let a number of sub-leases. Paul Hines is superintendent.—The Rubie Mining & Leasing Co. has resumed work at the Rubie and Lafayette mines of the Princess Alice Gold Mining Co.—Sherman M. Bell has secured a two-year bond on the Janet W., Laura M., and Lester W. claims, on Beacon hill, from the Republic Gold Mines Co.—The Isabella Mines Co. has leased the Empire State workings to T. R. Burbridge on a graded royalty basis for two years.—The return on a trial shipment from the Sunshine mine on Galena hill amounted to \$42 per ton. Fred Kreutzer, who is operating the property under lease, is stoping on a 4-ft. vein.—A heavy flow of water was cut in the heading of the Roosevelt Deep Drainage tunnel, the amount being estimated between 400 and 500 gallons per minute. The average progress is from 15 to 16 ft. per day.—High-grade ore is again being shipped from the Crescent mine on Womack hill.—Chas. Anderson and associates, operating the Dexter property on a sub-lease, have opened a flat vein on the 800-ft. level that assays from \$12 to \$30 per ton.—The structural steel work for the new mill of the Portland Gold Mining Co. is nearly complete, and the machinery is on the ground. It is expected that the plant will be ready for operation by the first of the year.

IDAHO.

BOISE COUNTY.

(Special Correspondence).—At Quartzburg the 20-stamp mill of the Gold Hill & Iowa Mines Co. is being moved from its former site to the Gold Hill shaft, where it will be reconstructed and some new equipment will be added. Electric power is being provided for. E. E. Carter is manager.—The Edna mine, 24 miles northwest of Idaho City, in charge of C. R. Watson, is a silver property, which has been equipped with a plant for cyaniding the ore by a process similar to that in use at Pachuca, and Guanajuato, Mexico. Quartzburg, October 25.

CUSTER COUNTY.

(Special Correspondence).—The Greyhound mine, near Stanley Basin, is in charge of Steven Smith, who has the property equipped with a 10-stamp mill and round water-jacketed smelting furnace, of 40 tons capacity. The settled slime is being briquetted. The mill has been started but not the smelter.—The Sunbeam mine, of which Werner Ziegler is superintendent, yields a medium-grade gold and

silver ore in a rhyolite gangue. Until recently two Monadnock mills have been in operation, but work is now suspended while additional machinery is being installed. It is reported that four Chilean mills are to be installed. A hydro-electric power plant is being constructed on the Salmon river, 12 miles from the mine. The latter plant is to be finished this fall.—The Lost Packer, situated in the northwestern part of the county, is being further developed under the superintendency of J. P. Boyle. The vein is in schist country rock and is intersected by several porphyry dikes, making it difficult to follow. An 800-ft. cross-cut, which is nearly finished, will cut the ore at a depth of 1000 ft. This is chalcopryite and assays high in gold. The smelting plant, erected on the property two or three years ago, has not been operated this season. The mine is 130 miles from Mackay, the nearest railroad station.

Mackay, October 23.

LEMHI COUNTY.

The Pittsburg & Gilmore railroad, being built from Armstead, on the Butte branch of the Oregon Short Line, to the mining districts of Lemhi county, will probably be finished as far as Junction by January 1. Later an extension is to be made to the Gilmore mine at Gilmore, and the company contemplates a further extension from Junction down the Lemhi river to Salmon City. The Gilmore mine is opened by a 400-ft. vertical shaft, and has a large amount of lateral development.—The Kittle Burton, in charge of R. L. Edwards, is situated at Ulysses, where a 2000-ft. Leschen tramway has been erected. Re-grinding machinery is to be installed in the 15-stamp mill, increasing the capacity to 100 tons per day. This is 30 miles north of Salmon City.

ILLINOIS.

In the Sandoval oil field there are now five producing wells. Drilling throughout the western part of the State is active. Developments at Du Quoin are watched with especial interest as the geological structure there is known to be favorable.

KANSAS.

CHEROKEE COUNTY.

There are many features of improvement in the Baxter Springs camp. There are two tendencies in that field which will probably mean a betterment of the conditions there, the buying of the land by the operating companies and the enlargement of the mills with installation of careful sizing systems. New laws make it possible now for the Indian owners to sell the lands and the operators are taking advantage of the opportunity.—The Mission company is erecting a new 500-ton plant and is operating the old small one while the work is in progress. The company is working a thin deposit of ore, milling about 4%. The Mason company has enlarged its plant to 250 tons and is installing Foust jigs.—Pittsburg men have taken over the Sweeney mill and after a general overhauling and installing of new jigs have started operation. The ore runs about 4%.—A new company has begun prospecting in the Cave Springs camp south of the Herald mine, hitherto the sole producer of this field. The company has cut ore from 85 to 150 ft. The ore is mainly zinc blende.

Baxter Springs, October 22.

MISSOURI.

JASPER COUNTY.

(Special Correspondence).—Perhaps the most prominent feature of the Joplin district at present is the development of new fields on the outskirts of the older camps.—In the Chitwood camp there are five or six drills busy on the Granby land. The same company has a number of men prospecting west of the main Spring City camp.—A recent find of rich shallow ore in the Carl Junction camp at a depth of only 3 ft. has caused a great rush to that camp and a demand for leases on the Bristow land.—The Cunningham land, southeast of Duenweg, has been laid off in acre lots and is to be leased for mining purposes. The property lies in the deep sheet ore belt.—Henry Crossman has secured a lease southeast of the Duenweg and has installed a drill to prospect it.—One of the best of the newer fields

is the Van Hoose 40 acres, north of Neck City, recently sold to St. Louis capitalists. Upon this land three companies are planning the early erection of mills.—The old Boston-Get There mine, in the Prosperity camp, is being rejuvenated after an idle period lasting some years. The old American Beauty 300-ton mill No. 2 is to be removed to the new tract. This was one of the first sheet ground mines in the camp.—The old Florence, at Midway, has been taken over by a new company and is now called the Green Dog.—The Overland mill, at Duenweg, has resumed operation after a two-year shut-down.—The Little Pearl on the Continental land west of Joplin has made a good find of lead ore in a drill-hole at 98 ft. continuing to 108 feet.

Joplin, October 22.

NEVADA.

CHURCHILL COUNTY.

(Special Correspondence).—The Nevada Hills is preparing to exploit the rich shoot recently opened below the barren zone in the vein. A 40-hp. gasoline engine has been ordered to operate the compressor, and steady shipments are being maintained. W. H. Webber is manager.—The Fairview Eagle is sinking from the 200-ft. level and shipping ore.—The Nevada-Fairview, operated by lessees, has purchased a 50-hp. gasoline hoist and small compressor.—A vein of ore said to run from \$20 to \$60 per ton in gold, silver, and copper, is being opened on the Nevada Crown. Fred Young is manager.—Lessees on the Dromedary Hump and Golden Boulder have installed hoists and are opening good veins.

Fairview, October 21.

ESMERALDA COUNTY.

Dividend checks, amounting to \$1,067,000, will be distributed to the Consolidated stockholders on October 30. The company is installing six Chilean mills in the Consolidated plant which will bring the output up to 900 tons per day.—A bunch of \$200 ore was opened in a stope on the 125-ft. level at the Daisy property.—The shaft at the Goldfield Annex is down 540 ft. in the dacite formation. The company is to sink to the 1000-ft. level and cross-cut.—Mitchell & Fairfield have secured a bond on the Blair No. 2, Four Timer, Daisy, Gold Bar, and Alamo claims at Silver Peak for \$75,000.—The operators of the Diadem lease, at Diamondfield, are sacking rich ore for shipment.

NYE COUNTY.

(Special Correspondence).—Exploration work of the Tonopah Mining Co. is practically confined to the lower levels of the Mizpah, Silver Top, and Red Plume, while the bulk of production continues from the old workings. The weekly bullion shipments are averaging about \$49,000.—The Belmont shaft has passed through the wet belt and entered the dry andesite at a depth of 780 ft. At the 1100-ft. point in the old workings a station is being cut from which a three-compartment shaft will be raised to meet the Belmont shaft.—The Tonopah Extension is rapidly proceeding with the erection of its new mill.—The Toquima Mining Co., of Boston, has taken over the Round Mountain Power & Water Co., Solid Gold Mining & Leasing Co., the Sierra Power & Water Co., and a controlling interest in the Round Mountain Daisy Co.—It is announced that the Sphinx mine and mill will resume operations within a few weeks.—The War Eagle Mining & Milling Co. has commenced excavation for a sampler at Manhattan. The manager promises to have it in operation before the end of the year.—The Johnnie Mining & Milling Co. has placed an order for a 10-ft. Chilean mill. Sixteen Nissen stamps are now in operation. E. Price Mitchell is manager.

Tonopah, October 22.

STOREY COUNTY.

(Special Correspondence).—The north drift on the 2450-ft. level of the Consolidated Virginia is being re-timbered and this portion of the mine will be thoroughly developed.—It is reported that the new vein on the 2300-ft. level of Mexican assays \$65 per ton. The winze from the 2000 is down 230 ft.—The output at the Ophir has been increased to 300 tons per week. On the 2000-ft. level a good vein of \$19 ore is being opened.

Virginia City, October 22.

WHITE PINE COUNTY.

At the Millard claim, near Lane City, the lessees are mining ore from a 3-ft. vein and shipping to the Salt Lake plants.—The adit at the Duzette group cut a 20-in. vein of lead ore at a depth of 175 ft. John Steele is in charge of the work.—A consolidation is to be made between the Nevada Consolidated and the Cumberland-Ely companies of their properties at Ely. This will result in the active exploration of the Cumberland-Ely ground and a more economical treatment of the ores at Smelter.—The old shafts that were sunk on the Clipper and Monarch claims of the Ely Central in early days have been cleaned out and some excellent copper ore found. Edward Hoffman is consulting engineer.

OREGON.

BAKER COUNTY.

(Special Correspondence).—The Indiana Mining Co., with offices in Baker City, has done 6000 ft. of development on its property 20 miles northeast of Baker City. There are two veins, 200 ft. apart, in altered rhyolite containing 5 to 6% copper, and \$3.50 per ton in gold and silver. They are opened from a 375-ft. shaft, there is 5000 ft. of development on the 300-ft. level.—The Rainbow mine, in Mormon basin, belongs to the Commercial Mining Co., for which W. E. King is manager. A 20-stamp mill is being run on a good grade of ore. It is reported that they have one ore-shoot 10 ft. wide, and 129 ft. long, sampling \$26 gold per ton.—The Humboldt Gold Mining Co., owner of the Humboldt mine, also in Mormon basin, is controlled by James A. Howard and associates of Baker City. Forty-five tons per day is being milled in a 10-stamp mill equipped with plates and concentrators. The saving on the plates amounts to 60% of the assay value, the balance being saved in concentrate. The tailing assays 80c. per ton. The ore assays from \$8 to \$150 per ton. The total development measures 4000 ft. Five additional stamps will be installed next spring.

Baker City, October 26.

JACKSON COUNTY.

(Special Correspondence).—The Grey Eagle mine, belonging to the Oregon-Gold Hill Mining Co., of Portland, has installed a 10-stamp mill and cyanide plant, which is expected to be in operation by December 1. They have a steam power plant but electricity will be installed later. The processes will consist of amalgamation, concentration, and cyanidation. They purpose cyaniding the concentrate as well as the table tailing. J. R. Wolfe is general superintendent. The mine is six miles north of Gold Hill.

Gold Hill, October 25.

TEXAS.

PRESIDIO COUNTY.

(Special Correspondence).—Attention is being attracted to the Shafter mining district by the prospecting and development work that is now going on there. A rich vein of silver-lead ore was recently opened up there by Young Brothers, of El Paso. Regular shipments of ore are being made from this property to the smelter and the returns are said to be large. This new mine is situated near the famous silver-lead mine of the Cibola Mining & Milling Co. which has been a steady producer for 25 years and is said to have yielded about \$6,000,000 during that period. The Shafter district is situated 40 miles from Maria, the nearest railroad shipping point. Several other promising claims in that district are being exploited and it is expected that a number of them will be developed into good shipping properties before a great while. The question of building a railroad into the district is being agitated.

Shafter, October 22.

UTAH.

BOX ELDER COUNTY.

Operations have been resumed at the Century mine of the Century Gold Mining & Milling Co., in Park valley. There is a good mill on the property which is credited with a production of \$212,000. Patrick Sheahan is in charge of the work.

JUAB COUNTY.

The new three-compartment shaft at the Lower Mammoth

property will be finished to the 2000-ft. level about November 1 when the company will cross-cut to the ore.—The Guggenheim interests have purchased the Woodman group in the Deep Creek district for \$280,000. A 50-ton mill is to be erected on the property within the next three months.—Operations at the Grutil mine, in East Tintic, were suspended for a few days on account of an accident to the hoist.—A carload of ore per week is being shipped from the Ajax mine at Eureka. The shaft will be sunk to the 1300-ft. level.

SALT LAKE COUNTY.

(Special Correspondence).—W. H. Janney, superintendent of the Copperton mill of the Utah Copper Co., has patented and put into use what he calls a pulp extractor, for discharging the concentrate from the vanner boxes. It consists of a spiral shaft, set in the bottom of the V-shaped vanner box, where it turns at about 35 revolutions per minute. It is in reality a screw conveyor, operated by the vanner gearing. Its working creates little or no agitation of the pulp and slime, thus not interfering with the settling of the particles. Allowing a vanner box to fill, this conveyor can be set in motion and made to discharge the accumulated concentrate in 15 to 20 minutes. Mr. Janney states that this device may be applied in discharging the pulp from V-shaped settlers and pulp-thickeners.

Bingham, October 24.

SUMMIT COUNTY.

The Iowa Copper Co. has stopped shipping from its mine at Park City for the winter as the expense of hauling during the winter months is excessive. Development will be continued throughout the wet season and shipping resumed in the spring. A. M. Spooner is manager.

CANADA.

BRITISH COLUMBIA.

(Special Correspondence).—At the annual meeting of the Consolidated Mining & Smelting Co., of Canada, Ltd., held in Toronto, October 12, the capitalization of the company was increased from \$5,500,000 to \$7,500,000. During the past year the company has augmented the plants at its different mines at a cost of \$164,951; the amount expended on new mines acquired was \$55,766; land at Trail, \$22,070, making a total of \$242,787. This sum was derived from the company's operating profits. The operations of the Consolidated company for the past year show a profit of \$329,000. This figure is arrived at after writing off \$153,218 depreciation; \$16,650 for sundry items; \$24,444 working costs on Richmond-Eureka venture; and \$563,413 expended in development. The figures shown in this annual report indicate marked progress, especially where the Trail smelter and refinery and the Rossland mines of the company are concerned. At the Centre Star group here the output was the heaviest that it has been since the Consolidated company took hold, the gross value being nearly \$2,000,000. The mines are in good working condition today and with large ore reserves blocked.—The lessee of the Velvet-Portland group has got a small force of men at work about the property.—The B. C. Mining & Development Syndicate, of Rossland, has a small force at work on its property near Marysville.—The annual report of the Granby Consolidated M. S. & P. Co., for the year ending June 30, 1909, which has just been made public, is quite a favorable one when the many different drawbacks are considered. The gross earnings of the company for the year amounted to \$3,983,536 while the net profits were \$681,134, or 17% on the total earnings. The total mining, smelting, converting, and marketing charges per ton were \$3.20, which, after deducting gold and silver, made the cost price of copper to the company 10c. per lb. which was 0.0024c. lower than for the preceding year. Owing to large quantities of ore being caved during the year the grade was low, the average extraction being 21.81 lb. copper, 0.2724 oz. silver, and 0.0434 oz. gold per ton. The difference in grade of ore, however, is more than offset by the saving in mining costs when the run of the stopes is put through the smelter. During the past year this company paid \$270,000 in dividends, and has on hand in cash and copper a total of \$600,459. The average price obtained for copper during the year was \$13.22, and

for silver, \$51.25, which was a little lower than during the previous year.—The work of the Canadian Geological Survey in the platinum fields of the Tulameen district has been finished for the year and Chas. Camsell, geologist, who had charge of the work, has taken with him to Ottawa specimens and data that will furnish much work in the laboratory during the winter months. Considerable platinum has been found in the alluvial wash of the rivers of this district, and it is hoped that the researches of the Geological Survey will aid in placing the mining of this metal in this district upon an economical and profitable basis.—Ore shipments from the Sardon district have been light owing to the railway being damaged by a slide, but it is anticipated the Canadian Pacific will be ready to take ore from the Sardon mines in a week or ten days and it is expected that the shipments will be quite heavy until the ore now in storage is taken away.—The Canadian Marble Co., of Nelson, is expending \$150,000 on a plant for its quarries at Marblehead. About 70 men will be employed when running full force.—The output of coal at

Centre Star Mine.

the mines of the Crows Nest Pass Coal Co. increased heavily during the last few weeks.

Rossland, October 21.

CHILE.

The Braden Copper Co. of New York has just purchased 106 Frue vanners for its new concentrator. The machinery is being shipped to Valparaiso.

COLOMBIA.

The Gualcala Mines Co. of New York and Colombia has purchased a sectionalized mill for its mine in the latter country. The ten stamps, tube-mill, and cyanide plant are sectionalized to a 200-lb. limit.

MEXICO.

OAXACA.

(Special Correspondence).—At the Esquadra mine at Taviche the company is stoping on a 3-metre vein that assays $1\frac{1}{2}$ kg. silver per ton with a small amount of gold. Local capitalists have secured an option on the property.—A main working shaft has been started at the Andes-Bullion mine.—Ground has been broken for the foundation of a new 10-stamp mill at the Soledad mine in the Totolapam district. The mill will consist of two 5-stamp batteries, a tube-mill, and a cyanide plant.—A. E. Place has completed the sampling of the old Sorpresa mine belonging to C. T. Young.—A mill consisting of an Allis-Chalmers 5-stamp battery of 1050-lb. stamps, a 16-ft. amalgamating table, Overstrom concentrator, and a Frue vanner, has just been completed for the Rio Seco Mining & Milling Co., near the Parian station on the Mexican Southern railroad. George W. Edmund is superintendent.—At the Iowa mine in the Taviche district, sinking operations are being continued in the main workings, and a cross-cut is being driven on the 100-ft. level.

Oaxaca, October 19.

Special Correspondence.

NEW YORK.

Nevada Con.—Cumberland-Ely Consolidation. — Copper Stocks and Metal Prices.—La Rose Directors Chosen.—Lewisohn Silver and Copper Mines.—Guanajuato Changes.

Undoubtedly the most important event in mining circles during the week in New York was the consummation of the plans to merge the two premier copper companies at Ely, Nevada. There has been a vast amount of discussion and conjecture as to the terms upon which the merger would finally be made. It was said at first that the larger interests in Nevada Consolidated were insisting upon a basis of $3\frac{1}{2}$ shares of Cumberland-Ely for one of Nevada Consolidated. The minority interests in Cumberland-Ely were evidently strong enough to force a compromise and the call as issued for the stockholders' meeting to be held November 2, gives the basis of the intended exchange at $3\frac{1}{4}$ shares for one. The Nevada Consolidated will, upon ratification by the stockholders, issue 400,000 shares of new stock to be exchanged for the 1,300,000 of Cumberland-Ely. So far as the market is concerned the effect of the merger has been entirely discounted and while both issues, in common with the rest of the market, have ruled fractionally higher for the week, there has been no great activity in them. Some of the other Ely issues have been quite the centre of attraction. Some spectacular advertising has been put out to advance Ely Central, with the result that that part of the public which gives greater consideration to market quotations than to mining probabilities and ore reserves, has been loading up heavily with the shares. Ely Consolidated has also been dragged out of obscurity, where the tired holders, who largely refused to pay the two assessments levied against the shares, were quite content to allow it to rest, and has been moved up in price from the point of default for non-payment of the assessment to 65c. per share. Many of the other low-priced Ely stocks in which there has been no activity for months, have come to life on the strength of the market being made through publicity campaigns and a small sized boom in Ely stocks seems fairly under way. The leader in copper stocks outside of the Ely shares has been Tuolumne, which, while the volume of trading has been comparatively small, has the centre of attack by a large and growing short interest in the Street. In the face of pressure the stock moved up and seems to more than hold its own on the strength of its public support. The shares have been recently listed in Boston, and Boston houses have been doing quite a little in the way of arbitrage.

There were some unexpected changes made at the meeting of the board of directors of the La Rose Consolidated Mines Co. on Wednesday. John McMartin, Duncan McMartin, Henry Timmins, and Frank W. Holmes resigned as directors and their places were filled by the election of George W. Stevens, Shirley Oglivie, Alexander Pringle, and Victor E. Mitchell, all of Montreal. The gentlemen who resigned were pioneers in the Cobalt field and were interested in many properties when its future was wholly problematical. It is supposed that the changes are connected with the recent drive which was made against La Rose in the New York market, though just what the connection is has not, as yet, appeared. The present board of directors, through the president of the company, D. Lorne McGibbon, has given out a statement that the changes were made at the request of some of the largest holders and the present board had assumed responsibility only after a full examination of the physical condition of the property, as well as the financial status of the company, and finding both to be wholly satisfactory.

The copper metal market remains unchanged. Buyers have become exceedingly cautious and such sales as are made are not enough to give the market any buoyancy. The report of the Copper Producer's Association, made public last week, showed an additional accumulation of surplus copper, and had its effect upon buyers, causing

them to feel no haste as to purchases for future delivery.

The growing talk of a copper combine has reached such proportions that it is now dignified by explicit and repeated denials from the various interests said to have been actively considering the matter. The denials are really of little moment. Some kind of an organization is inevitable.

The Silver Mines Exploration Co., a Lewisohn organization operating in Canada, has declared its regular quarterly dividend of $1\frac{1}{2}\%$, with an extra 1%. The control of the Kerr Lake, a large interest in Otisse, as well as the other interests of the Lewisohns in Canada, are held and managed through the company. The General Development Co., the Lewisohn holding company through which the Miami Copper Co. and several other copper properties in the Southwest are operated, has just received the report of Walter Harvey Weed on the Ray Central Copper Co. Mr. Weed's report shows some 2,700,000 tons of ore in reserve above the 200-ft. level averaging between 2 and $2\frac{1}{2}\%$ in copper.

Negotiations are on for the taking over of the Jesus Maria mine, of the Guanajuato Amalgamated Gold Mines Co. by the Oro Grande mines controlled by the Securities Corporation, Ltd., of New York. The Oro Grande wants the Jesus Maria mill for its unequipped properties in the La Luz district. The Proprietary Mines Company of America announced this week that it had purchased a large block of stock giving it control of the Mineral Development Co., operating the Nueva Luz mine at Guanajuato, Mexico.

TORONTO, CANADA.

Output.—Stock Market.—La Rose Fluctuating.—Silver-Leaf.—Gowganda.—Geological Work.—Western Zinc Smelting.

Cobalt ore shipments for September amounted to 2505 tons, which showed a slight falling off as compared with those of August, and a large decrease in comparison with the 3049 tons shipped in September, 1908. The returns for the first nine months of the year, however, showing a total of 23,116 tons, indicate a substantial advance over the corresponding months of 1908, when the shipments amounted to 17,027 tons. The Wettlaufer, a South Lorrain mine, figures in the list for September for the first time with a consignment of 25 tons.

The stock market has been unsettled, with a decided preference for the dividend-paying stocks and continued weakness of the cheaper issues. This feeling is largely attributable to the litigation between the Nova Scotia and Peterson Lake companies, involving also a suit for a large amount brought by the Peterson Lake against J. A. Jacobs and E. M. Steindler, former officials of the latter company. Into the complicated charges and countercharges it would not be profitable to enter, but the determination reached by the shareholders of the Peterson Lake at a general meeting held here on October 6, to reject the overtures of the Nova Scotia and of Messrs. Jacobs and Steindler for a settlement by arbitration, and to push the litigation to the bitter end, has done much to weaken public confidence and to depress Cobalt securities. The surprise of last week, however, was the totally unexpected and still unaccounted for slump in La Rose, which fell from about \$7.50 to a little over \$6. It has since been slowly recovering and all sorts of rumors have been afloat as to the decline. The drop was remarkable owing to the company having the previous week made a record shipment of 225 tons of ore, while its consignments for the month of September headed the list with 620 tons. It is stated in some quarters that the company is drawing too extensively upon its reserves and diminishing the quantity of ore blocked. An authoritative statement as to the actual condition of the mine will be necessary in order to restore confidence.

The property of the Silver Leaf has been leased to the Crown Reserve for five years, subject to a renewal for another five. The Crown Reserve is to pay a royalty of 25% on the output for the first term which is to be raised to 35% should the time be extended. The leasing company also undertakes to spend \$20,000 the first year and \$10,000 for each succeeding year of the term upon the property. On the Silver Leaf has been discovered a new vein 5 in. wide

yielding high-grade ore at the 100-ft. level. At the Cobalt Lake, while driving was being done on the vein near the McKinley-Darragh, a 3-in. calcite vein at right angles to the drift was found, and it has proved to be rich in silver. The Prince, adjoining the Temiskaming, has been purchased by an American syndicate headed by Colonel Bunker, president of the Badger mine, for a high figure. The annual statement of the Kerr Lake Mining Co. for the year ending August 31 is of a highly satisfactory character. The net earnings amounted to \$1,129,047, and the company paid dividends during the year to the amount of \$480,000. The average monthly output of silver was 227,387 oz., being a total yield of 2,668,648 oz. from 1072 tons of ore averaging 2489 oz., and 600,000 lb. of screenings. The cost of producing was 12.38c. per ounce. Some rich ore is being taken on the Wettlaufer, in South Lorrain, at the 110-ft. level. Several of the samples estimated to carry over 8000 oz. have been placed on exhibition at Haileybury.

The road from Elk Lake to Gowganda, which was expected to afford a means of communication during the winter, will not be finished this season. The development of the camp is interfered with owing to the difficulty of getting in machinery and supplies. An important strike has been

Cobalt Before the Fire.

made at the O'Kelly mines. A large silver-bearing vein was discovered some months ago which has been stripped 800 ft. Stringers were met running from this vein, one of them so rich that a test pit was put down. At a depth of 8 ft. the vein had widened to 3 in. and was found to be high-grade ore.

The Bureau of Mines has been actively conducting explorations during the season which are likely considerably to extend the boundaries of the known silver-producing area. The Gillies Limit, lying to the south of the properties already sold, has been examined, and the geological formation found to be similar to that of Cobalt which encourages the expectation that valuable discoveries may follow a closer investigation. W. G. Miller, Provincial Geologist, is now making an investigation of the Gowganda district.

Overtures have recently been made by Western men to the Dominion Government, with a view to having the zinc industry in the Nelson district placed on a bonus basis, somewhat similar to the present status of the lead industry. The zinc question has been a hard nut to crack in recent years, owing to the fact that many of the lead mines have practically developed into zinc mines as the work progressed in depth. The Nelson electric zinc smelter has proved a success commercially, but at present is closed for lack of funds. The capacity of the present plant is 10 tons per day, but this should be increased to 30 tons, and there is a movement for the raising of funds to go on with the work.

SALT LAKE, UTAH.

Heinze Coming West.—Smelters Want Ore.—Slime Process at Mercur.—South Utah Mines.—Ray Con. Gets More Ore.—Majestic.

F. Augustus Heinze has left New York for the West. He will go first to Butte and then come to Utah, to confer with the managers of Ohio Copper, Bingham Mines, and Western Utah Copper. The Ohio Copper mill is nearing completion. The matter of giving a contract for the smelting of Ohio concentrate will be taken up while he is here. The Garfield, United States, and International are all anxious to secure the copper output for their furnaces. Both the lead and copper smelting companies in Utah are reaching out for tonnage. The two lead smelting companies are receiving heavier shipments than six months ago, but still could treat almost 50% more. They have offered special inducements to the producers in every section, but the low price of metals prevents some of the larger concerns from increasing production. It is claimed that the United States company is in no hurry to re-build its copper furnaces at West Jordan, as there is not enough ore coming into the local market, aside from that which has been contracted to the Garfield plant, to warrant making the improvements.

Since the introduction of slime treatment for low-grade gold-bearing ores of the Mercur district, there are excellent prospects for a number of the producers of that camp. The slime process was first unsuccessful on the Con. Mercur ores, but after a number of experiments George H. Dern made some alterations, which rendered it available. The same process has made a dividend-payer out of the Boston-Sunshine group, which is now controlled by the same people. A company has recently been formed to treat the ores of the West Dip section of the district, where they have an ore containing from \$3 to \$4 in gold. A number of the old dumps in the camp are to be re-worked and mining will be renewed in the old workings. All this is beginning to give the district a lively appearance. Boston capitalists have become interested in a few of these projects. A. W. Chesterton, a large shareholder in the Con. Mercur, is here from Boston, and says that they are making a close saving in the Boston-Sunshine group. They have paid \$10,500 in dividends within the past four months, and are preparing to increase the capacity of the slime plant. The mines and mills of the camp are now furnishing employment to over 600 people.

The sale of the Newhouse Mines & Smelter corporation properties, in Beaver county, was consummated Wednesday. Shareholders will meet in New York on Tuesday of this week and transfer their rights to the new company, which is known as the South Utah Mines Co. Within a week to ten days the mine and mill will be re-commissioned. The reduction plant has been overhauled, and the plant will be capable of treating 1000 tons of ore per day. Tests indicate an 80% extraction from an ore said to contain 3% copper.

Daniel C. Jackling has just returned from an inspection of the Ray Con. and Gila copper properties in Arizona. He says at the Ray the drills in the upper end of the company's territory demonstrate that the porphyry deposits are found at a greater depth from the surface than in the ground first explored. At the same time the ore zone is thicker. The tonnage to the acre in the new ground is large, the latest talley sheets showing 400,000 tons as compared with approximately 300,000 tons in the lower end of the estate. The grade of the ore is about 3.2%. The checking up of the ore extracted from the underground workings shows slightly more copper than was indicated by drill holes. The discrepancy is not great, but is gratifying. The main working shaft, which is to be 300 ft. deep, is down 150 ft., and the second level is being cut at this point. Drifts are being run on both levels, and there will be four levels in all. The shaft comprises two 7-ft. compartments. The hoisting capacity is to be 400 tons per hour. Steel for the 5000-ton concentrating plant has been

shipped and grading is under way. The grade for the standard railroad from Kelvin to Ray, a distance of six miles, is 80% complete, and 25% of the rail and tie work is finished. Four drills are now developing the ore deposits in the Gila, which adjoins the Ray. With this increased equipment the development is being carried on more rapidly, and the results are highly satisfactory.

The electric power plant and compressor at the Majestic properties, in Beaver county, have been commenced. Alex. Moffat, general manager, says that the real campaign of extraction, and development to greater depths, will be inaugurated at once. During the past year the company has opened silver-lead orebodies between the 300 and 500-ft. levels, and though the water-level has been reached, the shaft is being sunk 600 ft. A pump has been ordered and serious trouble with the water is not anticipated. In the meantime development of orebodies above the 500-ft. level, where the water was first encountered, is being continued and 4 to 8 ft. of ore for a distance from north to south of over 120 ft. has been found. In places the deposit is 15 ft. wide. The average grade of the ore shipped to date is 25% lead and 20 oz. silver. Some of the stopes show the higher grades while the drill cores from below the water-levels show as high as 60% lead and 80 oz. silver. The company is confident of success. After this mine is in operation it is planned to open the copper deposits in the Old Hickory and O. K. groups. A large tonnage of ore containing $2\frac{1}{2}\%$ copper and 20% excess iron occurs in these properties.

BUTTE, MONTANA.

Copper Combination.—Ryan Policies.—Copper Costs.—Green Copper and the Washoe Copper Company.

The Amalgamated and Cole-Ryan interests are said to be working to bring about a copper producers' combine to regulate production and price of copper, and to have the co-operation of J. P. Morgan and the Guggenheims. It is even stated that formal announcement of the fact is not far off. Rumors of negotiations have been current in Butte ever since John D. Ryan was elected president of the Amalgamated Copper Co. Mr. Ryan has always been an advocate of a better organization of producers, and his position gives him an opportunity to bring about such a combine. He has advocated a policy of expansion for the Amalgamated company, the acquisition of new mines and new ground, and also favors a policy of conservation, of great economy, and decreasing waste. If he is working for a copper combination it is to save the big deposits from depletion, as much as for any other reason. He believes that before many years a pound of copper in the earth will be worth several pounds of copper now in storage. He has constantly urged the necessity of cheaper production at Butte, and has accomplished a great deal. When he first became managing director of the Amalgamated it cost that company fully 12c. to produce and market a pound of copper. At some of the mines the cost was as much as 13c. Today the average is not in excess of 10c. per lb. The saving of mineral has also been considerably increased, although the loss still is about 20%. The loss is in tailing. This is re-worked by a leaching process but only part of the metal present is even then recovered. While the Amalgamated Copper company's metal costs about 10c. per lb. to produce and market, several of the companies run a little higher and one or two lower. For instance, the Parrot copper costs probably 11c. or more, Washoe and Trenton fully as much, Butte & Boston costs about 10c., and Anaconda produces about 93,000,000 lb. per year at a cost slightly under 10c. Boston & Montana, producing more than 100,000,000 lb., turns its copper out at 9c. per pound. The two Cole-Ryan companies, the North Butte and Butte Coalition, do better than any of the Amalgamated companies. Coalition copper costs about 9c. per lb., which includes the heavy expenditures for new work. North Butte produces at a cost under 9c. per lb., which also includes a large amount of new work charged to cost of production.

If the decision of the district court is sustained on appeal, the Washoe Copper Co. will be deprived of a very

valuable vein in the southern part of the Butte district. It was located as a quartz lode less than a year ago and called the Green Copper. It is situated within the boundaries of a tract of ground that has been owned by the Washoe company for many years, but its title is derived under a placer patent issued by the Government about 30 years ago. The locators of the Green Copper started to mine the ground last fall and were taking out some good ore when they were stopped by injunction. At the trial of the case they proved to the satisfaction of the court that the vein on which they located the Green Copper was known to exist and to be valuable for quartz mining many years before application was made for the placer patent. Under the law all known veins and lodes are excluded from the placer patent, and the court finds that a quartz vein was located and developed early in 1877, while application for the placer patent was not made until 1880. The decision gives the Green Copper people a width of 50 ft. along the vein for a distance of 1500 ft. At a depth of 100 to 200 ft. ore was mined a year ago that assayed 20 to 30% copper, and the vein is believed to continue to depth.

MEXICO.

Centennial Celebration.—Nazas Water.—Immigration Plans.—Railroad Earnings.—La Blanca Vein.—Zimapan Development.

September of next year will witness the Centennial of Mexico's stroke for independence, and celebration will be general, the program as announced, covering 27 days. Science, war, music, and history will all be well represented; there will be a fine exposition of flora and fauna; inauguration ceremonies for a number of important institutions will be attended with interesting parades, bands, and functions of one kind and another; but the event of most interest to the foreign visitor will be the grand historical pageant on September 15, the day on which the independence bell was first rung, and on the same day the theatres and amusement resorts will all be free to the public. On September 16 the unveiling of the great new monument to 'The Independence' will take place, followed by a fine military parade of thousands of troops. There will be innumerable balls, concerts, official ceremonies, fireworks, aviation contests, and expositions. Preparations are already being made for the great influx of tourists and visitors.

The Minister of Fomento, Mr. Olegario Molina, has been making a tour in the north and has been paying special attention to the question of the settlement of the distribution of the water from the Nazas river. No decision will be made public until after the Minister reaches Mexico City, and the Commission's report has been made. It is expected, however, that the Government will expend at least \$6,000,000 in improvements in the interests of the Nazas planters. The *Guanajuato Gazette* has made an interesting compilation of dividend statistics, comparing important gold and silver mines of about the same standing in the United States and Mexico. The following amounts show dividends paid up to July 1, 1909:

UNITED STATES.

| | |
|-------------------------------------|--------------|
| Alaska Treadwell | \$10,000,000 |
| Portland, Colorado | 8,317,080 |
| Stratton's Independence, Colorado.. | 5,028,560 |
| Tonopah, Nevada | 4,250,000 |
| Tom Boy, Colorado..... | 2,045,400 |
| Goldfield Con., Nevada..... | 1,866,775 |

MEXICO.

| | |
|---------------------------------|--------------|
| Esperanza | \$10,207,500 |
| El Oro | 5,333,260 |
| Peñoles | 4,366,685 |
| Sta. Gertrúdis & Guadalupe..... | 3,960,000 |
| Dos Estrellas | 3,780,000 |
| San Rafael | 3,179,938 |

The Federal Government has commissioned Federico E. Godoy, who was until recently Mexico's Minister to Cuba, to go to the United States and make a study of the immigration laws for the Department of Foreign Relations. This is with a view to the reform of Mexico's immigration laws. The Mexican Government is considering the question of

stimulating immigration. It is the opinion of some prominent foreigners, that reforms in the immigration laws will be useless unless reforms in the land and agricultural laws are first made, which will tend to break up the immense holdings of idle land in the hands of a few Mexican families. A stringent cumulative land tax on holdings over a certain size, on the lines of the New Zealand laws would be one solution of the problem. An increase in the wealth of the middle class agricultural population would tend to stimulate the demand for increase in silver coinage and thus indirectly assist the mining industry.

The result of the National Railroad merger was given in a report for the fiscal year ending June 30, which is as follows:

| | |
|------------------------------------|-----------------|
| Gross earnings | \$48,805,522.26 |
| Operating expenses | 29,166,893.33 |
| | <hr/> |
| Revenue from investments held.. | 1,386,094.44 |
| | <hr/> |
| | \$21,024,723.37 |
| Taxes, rentals, and depreciation.. | 2,781,636.45 |
| | <hr/> |
| | \$18,243,086.92 |
| Fixed charges | 16,975,943.88 |
| | <hr/> |
| | \$ 1,267,143.04 |

This balance was distributed as follows:

| | |
|-----------------------------------|-----------------|
| 2% dividend on first preference.. | \$ 1,153,316.00 |
| 5% for reserve fund..... | 63,357.15 |
| Carried forward | 50,469.89 |
| | <hr/> |
| | \$ 1,267,143.04 |

Nearly 3000 tons of machinery is on the way for the big hydro-electric power-plant on the Santiago river in Jalisco, the machinery being supplied by Seimens & Halske, of Berlin.

It may be of interest to know that the La Blanca mine,

General View of Pachuca.

at Pachuca, is on the same general belt as the Santa Gertrúdis. It is, in fact, an extension of the same vein, only one claim lying between the two properties belonging to the Real del Monte Co. It, therefore, seems that the report given out, that the La Blanca deal fell through, because the vein 'dipped' under the Santa Gertrúdis, was misleading, as this would appear to be impossible. Local gossip has it that the price asked was £500,000, with time payments, but that the brokers' commissions and promotion expenses brought the price up to a very large sum, and that there was not sufficient cash capital to pull the deal through. Added to this there was war in the promoters' camp over the division of the spoils.

The standard gauge railroad under construction from Pachuca to Zimapán Hidalgo, is well advanced, and as soon as the tunnel is completed, the line will be pushed to completion as fast as possible. The road will be about 100 kilometres long, and will cost between three and four mil-

lion dollars. At present only about 20 miles has been built, and the principal delay is the driving of the tunnel near Actopán, which will be about 500 metres long. At present the nearest railroad is at Sayula on the National lines, entailing a haul of about 46 miles. R. Honey is the principal backer of the enterprise, and the line is known as the 'Honey line'. Sydney Ludlow, the general manager for the Hidalgo Copper Co., at Zimapán, State of Hidalgo, says that development has been steadily pushed for the past four years on the copper lodes in their Concordia and Purissima properties, and that they have enough paying ore now blocked to justify the construction of a 200-ton smelter. Financial arrangements are being made with that in view. They will also install compressors, drills, hoists, aerial tramways, and the like. About 400 men are at work at the mines. Other mining companies that are of importance, are the Lake Zimapán Mining & Smelting Co., managed by R. F. Wrigley, and the La Cruz Mining Co., of which Miguél Taboada is president.

LONDON.

El Oro Mining & Railway Co.—Dharwar Reefs.—Tyee Copper.

The report of the El Oro Mining & Railway Co. for the year ended June 30 shows that 285,181 tons yielded \$2,442,374, of which \$2,149,091 was in gold and \$293,283 in silver, the total extraction per ton being \$8.56. The recovery was 91½% of the gold and 77% of the silver. The working costs in Mexico were \$5.42 per ton, which is a slight increase over previous years, due to the greater amount of work at depth and additional pumping requirements. With regard to the extraction, the directors are intending to still further extend the tube-mill outfit. The ore is to be crushed coarser and four more tube-mills are to be erected. It is estimated that with this new plant it will be possible to treat as much in the No. 2 mill as is treated in both mills at the present time, so that it will be possible to suspend operations at No. 1 mill, and in that way effect a considerable economy. It is reported that the recovery of the precious metals from the heavy sulphides in the lower levels is as complete as that from the oxidized ores. The ore reserves on June 30 were 383,269 tons, averaging \$9.10 gold per ton, a slight decrease in the tonnage as compared with last year. It has been difficult to continue development at depth owing to imperfect ventilation. The new shaft was down to 460 ft. on June 30, and should reach the 1000-ft. level in a little over a year. When this is completed the ventilation will be improved, and the development of the lower levels will proceed more satisfactorily. The English equivalent of the production was £498,244, and the mining expenditure, including depreciation, was £315,447. There was a profit of £11,000 on the railway, and of £21,361 on the sale of shares and dividends received. Dividends amounting to £172,125 were paid, being at the rate of 15% on the paid-up capital. The total distribution to date has been £1,181,187, which is just a trifle over the nominal capital of the company, £1,147,500. In addition £362,027 has been provided out of revenue for capital purposes.

The Dharwar Reefs mine in the Bombay presidency of India, controlled by John Taylor & Sons, has not turned out to be as good a property as was hoped. The company was formed in 1904, and, as developments were not successful, it was found necessary in April of last year to provide further working capital. The report for the fourteen months ended June 30 offers little encouragement. The results are distinctly disappointing, and in fact it has not been possible to supply sufficient ore to keep the mill going at capacity. During the 14 months, 21,574 tons was crushed, yielding on the plates 7477 oz. of bullion valued at £28,000. This was an extraction of 7 dwt., and the assay of the tailing was 3½ dwt. Great trouble has been met in dealing with the tailing, and it is only this month that the method of cyaniding has been settled on and treatment started. At first the extraction was hindered by re-precipitation of the dissolved gold by some electrolytic reaction, and experimental work was conducted for a long while for the purpose of determining some method of effecting the ex-

traction. It would be interesting to know what the difficulty was, but no details are published.

The Tyee Copper Co., Vancouver island, is passing through anxious times. Since the mines became exhausted efforts have been made to acquire other properties. So far none have been acquired, though substantial sums have been spent on options and examinations. There are now one or two being tried, but no definite decision has yet been made as to their suitability. In the meantime custom work is being sought for the plant at Ladysmith. An additional furnace has been erected, and the total capacity is now 12,000 tons of ore per month. During the year ended April 30 last the original smelter was only occupied for 7 months owing to scarcity of supplies, and the struggle for ores in competition with other firms is severe. The directors are not, nowadays, issuing such a complete balance sheet as they did when the company was devoted to mining, for the reason that it is not advisable to disclose the details of custom business. The loss on the year's operations, after making full allowance for depreciation, amounted to £22,000. The control is in strong hands and the chief shareholders belong to the Siemens circle. There is a large reserve fund, and still further capital would be available were there any encouragement for its profitable investment.

One of the most promising mining properties in Australia is the Great Fitzroy mine, 16 miles north of Rockhampton, Queensland. This was taken over by Bewick, Moreing & Co. two years ago, and has been most energetically developed. A year ago it was found desirable to increase the working capital, so the company was reconstructed with a nominal capital of £500,000. Of this, 375,000 shares credited with 18s. paid were given in exchange for the old shares, and the balance of 2s. paid in cash, yielded £37,500. Of the remaining 125,000 shares, 25,000 have since been allotted and the money paid. A year ago the ore reserves amounted to 334,000 tons, and on June 30 of this year they had been increased to 981,000 tons assaying 3¼% copper, 2.66 dwt. gold, and about 1 oz. of silver per ton. It is intended to develop for at least another year and fully investigate the extent of the orebody at the 400-ft. level. In the meantime the smelter is being kept at work chiefly on ore won in development. During the year ended June 30, 34,261 tons of ore was treated, producing matte containing 980 tons copper, 5990 oz. gold, and 32,499 oz. silver. A new concentrator and smelter are being erected and before long 18,000 tons of ore will be treated every month.

DENVER, COLORADO.

Conditions at Leadville.—Clear Creek Projects.—San Juan Output.—Cripple Creek News.—Wyoming Items.

Leadville is coming into prominence again. The panic of 1907 almost completely paralyzed this district. The metal market has recently been more favorable to the Leadville mines, especially those producing zinc. An increase of over 50% in the monthly tonnage for zinc ores took place in September. The recent strike of gold ore on the Highland Mary has stimulated work on the surrounding properties, such as the Grand Prize, the Curran, and the old Chemung. The South Evans section of the district is very active. Many of the lessees already operating here intend to continue throughout the winter.

Several changes in the ownership and control of various properties in the Clear Creek district have taken place lately. At Central City there is to be considerable development on the Little Pittsburg, by F. Crosby and associates of Kansas City, who purchased the lease on this property from Harvey Carl and Richard Broderick. The Russell and West Pewabic claims in the same district have been sold to Antoinette Burchell, of Sidney, Nova Scotia. The new owner has ordered the necessary machinery for shaft-sinking which will be commenced as soon as possible. A sheriff's deed has been recorded at Central City conveying the property of the Jefferson-Calhoun Mining Co. in the Russell district to F. A. Williams, a trustee for the company. A complete re-organization is planned. The New-house tunnel has entered some hard rock during the

past week. The breast of the tunnel is now on the far side of Nevada gulch. The management expects to reach the Gunnell vein in about six months, but, if the present grade of rock should continue, it will be considerably longer. The stockholders of the Georgetown Tunnel Co. have increased the capital stock from \$1,000,000 to \$5,000,000. One-half of the stock will be common and one-half preferred. The company intends to push work. The tunnel starts at the foot of Columbia mountain and will go completely through this and under the rich mines on Democrat mountain.

The Wilcox adit at Argentine is expected to intersect the Wheeling vein this week. It is being driven to reach the ninth level of the Stevens mine.

The Denver & Rio Grande railroad in the San Juan district was open for the shipment of ore and supplies for only six days in September. With this limited shipping period, the production was 825 tons of concentrate and 575 tons of crude ore. Should the railroad be kept in operation for the whole month of October a record output may be expected. An important strike of high-grade silver ore was made in the San Antonio mine, on Red mountain, during the first part of the month. The ore is rich in stromerite, and resembles the ore discovered on the Yankee Girl several years ago.

The State Mine Inspector's report for the Cripple Creek district shows only 13 fatalities during the past year. Most

Mineral Belts of Colorado.

of the accidents have been caused by drilling into missed holes. Falls of ground such as killed a shoveler in the Roosevelt tunnel recently have been rare. The drainage tunnel is handling more water now, although there has been no change in the character of the rock. The option on 72,500 shares of the El Paso stock held by Allen L. Burris has been taken up. This is the largest single transaction on the Colorado Springs exchange for some time.

The little mining town of Dillon, Wyoming, has been destroyed by fire. This town is near the mine terminus of the famous 16-mile aerial tramway which connects the Ferris-Haggerty mine with the smelter of the United Mines & Railway Co. at Encampment. The New Rambler mine, near Holmes, Wyoming, has been shipping steadily for two months to the Argo smelter at Denver. Since this smelter has served notice that it will discontinue about December 1, the ore will hereafter be shipped to the Omaha plant of the A. S. & R. company. In view of the longer haul, the Union Pacific has reduced its freight rate to Denver 50c. per ton, and the Laramie Plains line has reduced its rate 10c. to help out the producer. The ore is covellite containing an important amount of platinum and some gold.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Deflecting Angles with a Thirty-Foot Tape.

The Editor:

Sir—The method described by Lee Fraser in your issue of October 2 calls to mind a similar method and table calculated by Frank G. Wolfe, engineer of the Scranton Coal Co., and published in *Mines and Minerals* for June 1908. For your information I enclose a copy of the diagram and description of the method.

"A mine foreman or superintendent frequently wishes to lay off an angle in the mines when he has not a compass handy, or it may be that on account of iron nearby a compass cannot be depended upon. With an ordinary tape, such as nearly every foreman carries, an angle can be laid off closely enough for all practical purposes as follows: Example, from the point A on the line AB to turn an angle 50° to the

left. To do this, fasten the 0 end of the tape at A, then stretch the tape to B, a distance of 10 ft., and fasten the 10-ft. mark at B, next find the 30-ft. mark on the tape, carry and fasten it at A. This will leave 20 ft. of slack tape between A and B. For an angle of 50°, find the 19-ft. mark on the tape, and draw the tape tight from both A and B. The tape-line from A to the 19-ft. mark will make an angle of 50° at A from the line AB. For an angle to the right, use the same measurement on the right of the base-line."

RUFUS J. FOSTER.

Scranton, Pennsylvania, October 14.

[The method Mr. Foster mentions is so simple that we take pleasure in reproducing the diagram and explanation, with our thanks for his courtesy.—EDITOR.]

Excess Ground in Mining Claims.

The Editor:

Sir—Referring to your article, and to that of Mark R. Averill in your issue of October 9, I can not see why you both seem to avoid the question of an excess in length. This is rather the more important of the two. I regard Mr. Averill as wrong in saying

that a locator can elect which end to cut off. The location notice or 'stake' is the inception of every mining title; a man puts up his 'notice' thus, "I claim 500 ft. north and 1000 ft. south on this vein, etc." When it is discovered that he has set his end stakes 600 ft. north and 1000 ft. south, I think that he can be compelled to drop the excess from the north end, provided, of course, that there is an intervening claim for that excess before he makes an amended location. If there be no intervening private claim, it is beyond question that an amendment or re-location can be made at any time, in any direction, and to any extent within the statutory limits, prior to a patent survey. If an adverse be made to a patent application I believe that my rule should hold good, and after a patent has issued I do not see how the question can reasonably be decided otherwise. I believe that there has been some court decision declining to require an owner to cut off anything from a patented claim found to be more than 1500 ft. in length; but in the case cited the excess was small (3 or 4 ft.). There would evidently be a limit to the excess which could thus be retained: but the limit of allowance would have to be decided by a court after hearing the conditions in any case.

Factors in Successful Gold Mining.

The Editor:

Sir—In your issue of May 1, F. J. H. Merrill says that "Mining properly handled is as safe as any other commercial industry." This statement is often seen, but its correct interpretation demands some study of the factors in successful mining as compared with other enterprises. The word mining itself, is vague, because there is a fundamental difference between gold and all other mining. Gold is

a metal that has a fixed mint value and a constant demand, though not a fixed value as measured in commodities; all other mining is governed by the demand for some metal or substance, having no fixed value nor any value in other commodities without an intermediate relation to gold as money.

All classes of mining except gold mining may be supposed to pay more than the money put into the ground. Since the advent of free labor, however, the best authorities agree that the cost of mining gold has been more than the mint value of the gold produced. The cost is variously estimated at two or three times the return, but exact figures are unattainable. My own observations in Europe, South Africa, and North America incline me to adopt the first named ratio. Wherever a successful mine occurs many unproductive ones are also present. This is not so true of coal, slate, or lead mines, or of cement works.

This is not because the profits are less than from gold mining nor because capital is required for development and machinery for operation, because this applies as well to gold mining. The reason lies

in the nature of the deposits of gold ores. In proportion to the cost of production, gold offers rewards much greater than other metals or substances. The demand for gold is constant and the value per ounce not subject to fluctuation.

The essential factors of successful mining are, (1) ore, (2) demand or market, (3) capital, (4) management. The demand for a metal or substance depends to a great extent upon gold, money, and credits. Therefore, in considering the essentials of gold mining, other forms are covered. A gold mine to be a successful enterprise must have ore that will pay, capital to develop the mine and install machinery, and efficient management. Of the failures of gold mines that have come under my personal notice, and by mines I mean those that have gone beyond the prospect stage and have produced more or less gold, I find them due to the lack of three essentials; ore, capital, and management in about equal proportions. I find failures due to lack of sufficient funds to put in proper machinery to be about equal to those due to lack of ore.

Ore is an indefinite term and can only be considered in relation to capital and management. What is waste with a few thousand dollars, may be ore with a larger sum. Ore, then, is rock which if mined and treated will, ultimately, pay back all the money invested with interest at a rate commensurate with the risk; provided the necessary capital for economical working has been available and the management competent. The rate proper of interest is indeterminate because it depends upon the individual idea of money making, but, comparing the rate with that which can be secured on first-class securities 20% would be the minimum.

If money be invested in railroad or municipal bonds these at maturity will be worth near the purchase price, if it be invested in a mine the land and plant are valueless when the ore is mined out, so that mining differs from other fields for investment in that there is no final value to compensate for the capital invested. All remuneration must come from the sale of the metal or substance mined. In comparison with gold mining, investments in bonds, and other related securities may be considered.

How long may the life of a mine safely be estimated? On this point depends the rate of interest necessary for compensation. Authorities differ in their estimates, but seven years is often considered a fair average; that is to say, the average life of a producing gold mine is about seven years. If I invest a thousand dollars in railroad securities which bear 5% interest and I invest the dividends each year at the same rate, at the end of seven years I have a thousand dollars worth of bonds and \$405 in interest, or \$1405. If I invest the same amount in a gold mine and invest my dividends each year at the same rate, I must have each year a dividend of about \$172; or 17% on my investment. If in both cases I spend my dividends each year, the rate must be 19%. It is now seen why intelligent investors in mining stocks demand from 20 to 25%. The difference between the 17 and the 25% measures the risk.

The value of a metal mined depends upon the demand for the metal. Demand is a psychological

phenomena. It depends upon the money and credits in circulation, which again depend upon business confidence. Lack of confidence or panic means hoarding of money and lack of credit, less money going into mining, and the appreciation of gold as measured in commodities. In other words gold is at a premium. Men released from other classes of mining rush to gold prospecting, mines are discovered, and when confidence is again restored the necessary capital is available for mining the precious metal.

We need no statistics to prove this. The past year has demonstrated that the prices of commodities are influenced by the amount of money and credits in circulation and the velocity of their circulation. The relation that this has to mining is evident. If the success of a mining enterprise depend upon capital, any condition that affects capital bears upon the success of mining.

If the gold produced each year entered our currency system and at the same velocity as at present, say, once a week, there would be a continual rise of prices of commodities and labor, or a depreciation of gold which would make gold mining generally unprofitable. Fortunately not more than a fourth of the gold produced goes into circulation. This no more than keeps pace with the increase of population. So while the velocity with which money and credits circulate is increasing, due to better means of transportation and communication, the rise in prices is slow and does not keep pace with the improvements in the arts of mining and metallurgy.

The amount of capital necessary to bring a mining venture to fruition is one of the most important things for an engineer to estimate, one that requires the most careful consideration, and one that is most often not considered at all. The number of mines that pay from the grass roots without any financiering are extremely limited. Each mine is a problem of itself, depending upon size of vein, extent of development, and future prospects. While it is mathematically true that the sooner a mine is exhausted the greater the profits, it would be just as unwise to put a 100-stamp mill on a 1-ft. vein of \$20 ore as to put a 5-stamp mill on a 100-ft. vein of \$3 ore. To determine the correct proportion is the business of the mining engineer, not that of the financier. It is most imprudent, in fact suicidal, to put the uneducated miner or the business men unaccustomed to mining and metallurgical operations, in charge of mining enterprises, particularly of gold mines. The mines that such men could work to advantage have long since been worked out, in our own country at least. The engineer or mine superintendent must now handle ores that under the best conditions return but a small profit per ton. To him shareholders must look for remuneration.

If the factors for successful mining are sufficient ore, adequate capital, and efficient management, and the relative importance of these be about equal, any mine-promoter or mine-financier who leaves out of consideration any one of the three is discounting the success of his enterprise just 33 per cent.

Granite, Oregon, September 27.

A WORLD'S RECORD IN TUNNEL DRIVING.

Written for the MINING AND SCIENTIFIC PRESS
By BURT A. HEINLY.

The world's record for tunnel boring is claimed by the engineers of the Los Angeles aqueduct with a run of 1061.6 ft. which was made during the 31 days of August at tunnel 17 M. This surpasses the run of 1013 ft. made in July on the Loetschberg tunnel in Switzerland, where all previous international records in tunnel boring had been broken. At Loetschberg the material is a limestone and the boring was accomplished with four air-drills. The formation in tun-

Red Rock Cliffs. Illustrating the Character of the Rock in Which the Tunnel was Driven.

nel 17 M. of the aqueduct is a sandstone of excellent quality for rapid work. The aqueduct record is remarkable not alone for the distance made in lineal feet but also for the low cost, which was \$6.48 per foot. The run is the result of an intense rivalry existing among the many different crews at work on the 240 miles of the great municipal water-works project, now in the third year of its progress, and was attended with some unusual conditions.

The bore has an inside dimension of 10½ ft. in height by 8½ ft. in width. The top portion is arched with a radius of 4 ft. 3 in. and the bottom is an invert with a radius of 9 ft. 6½ in. The sides are vertical. The tunnel is to be lined with an average thickness of 8 in. of concrete, but where timbering is required the concrete will be 12 in. thick.

When completed the tunnel will have a total length of 10,596 ft. under the Red Rock summit. So cheap has the excavation of tunnels along the aqueduct proved, that it has been found that a large saving can be made in distance and money by replacing some of the conduit planned by underground excavation. Tunnel 17 M. is the first and longest tunnel which is being excavated in section No. 1 of the Jawbone section under the new survey. It lies 28 miles north of Mojave on the edge of the Mojave desert in

what are known as the Red Rock bad lands. The heat here is surpassed only by that of the famous Death Valley, 100 miles to the northeast. During the month in which the record was made the daily temperature ranged from 100 to 117°, and was bearable only because of the great dryness of the atmosphere. The 'graveyard shift', which worked from 11 p. m. to 7 a. m., was required to obtain what rest it could under this condition, to which was added the intense sunlight of the desert-day and the pest of flies.

All the work was done by hand. The holes, which approximated 3 to 12 ft. in depth, were driven with hand-augers, and the muck was transported to the tunnel-mouth in muck cars drawn by mules. The 'lower-heading' plan was adopted in the work. Two miners were placed at the face and these were followed by two on a movable platform under which the muck car was run. The work of the latter two miners was to trim and cave to the required dimensions. Five men were employed handling muck and laying rails. Thus each shift was composed of four miners, five muckers, and a shift-boss. The shifts worked eight hours, and were under the direction of

Portal of Tunnel.

the general foreman and a tunnel superintendent. For each lineal foot of excavation 4.2 lb. of 40% 1⅛-in. ammonia powder and 2.2 lb. of black powder were used, making a total of 6.4 lb. to the foot. Each round was composed of eight shots arranged, three in a row across the top, three in the breast, and two as bottom holes. No machinery was used in the tunnel. In place of the usual blowing apparatus, ventilation was secured by driving holes through the roof of the tunnel to the surface, a distance of about 75 ft. No timbering was required.

At midnight of July 31 the face of the tunnel was in 964 ft. During the latter part of July the men petitioned William Mulholland to increase the force to three shifts. At the time they had a larger footage to their credit than had been made elsewhere on

the aqueduct, and they were confident that full-handed they would be able to win the world's record. The request was granted and the phenomenal pace was started as the new month began. The work was carried on without cessation until August 29, when a cloudburst in the mountains caused a partial flooding of the tunnel. A loss of 16 hours resulted before work could be again resumed. The total time employed was 728 hours. Thomas Flanigan, superintendent, and Benjamin Pruitt, foreman, were in charge, with A. C. Hansen as construction engineer.

The total cost of the month's work, including all field expenses, was \$6683.28 divided as follows:

| | |
|---------------------------|------------|
| Labor | \$5,429.13 |
| Live Stock | 259.20 |
| Materials | 995.80 |
| Freight and handling..... | 199.15 |
| Total | \$6,683.28 |

This is equivalent to \$6.39 per lineal foot, to which has been added an engineering expense of 9c. per foot.

The best previous American record, so far as is known, is that made on the Gunnison Reclamation tunnel in March 1906 with a run of 810 ft. In this instance the tunnel was driven under the unusual condition of a shift working at two headings from a shaft, the miners and muckers alternating at each of the two faces. The advancement of the tunnel face was followed with the keenest interest by aqueduct employees, and within a half hour after measurements had been made, each day the results were known and posted in every camp along the 240 miles of aqueduct.

The speed attained was to some extent due to the bonus system under which the men were employed. The rate of bonus depends upon the hardness of the rock formation. In this instance the average rate of progress for an eight-hour shift was established at 4 ft., with a bonus of 25c. for each foot in excess of this rate. Each shift actually drove 11.27 ft. Each man, therefore, employed underground received, in addition to his month's salary, a bonus of approximately \$55. The total bonus paid by the city was \$1508.86.

This makes the third tunnel record to be broken on the aqueduct within the year. In October 1908 the forces employed on the south end of the Elizabeth tunnel 26,964 ft. long, established a new, United States, 31-day, three-shift, record for boring in hard rock by a run of 466 ft. This eclipsed the Gunnison record by 17 ft. Again, in March of this year this same organization eclipsed its own record at the same tunnel portal by a run of 476 feet.

More than one-eighth of the Los Angeles aqueduct project comprises tunnel-work. The distance exceeds 33 miles, the tunnels ranging from a few hundred feet to several of more than 10,000 ft., and one, the Elizabeth tunnel through the Coast Range, having a length of 26,860 ft. More than half of the excavation of the entire 33 miles has been accomplished within the past 12 months. The most modern tools have been supplied, but the rapid progress can be traced largely to the *esprit de corps* of the engineering organization and the high rivalry to excel that exists among the different camps.

PRESENT CONDITIONS AT THE GARFIELD SMELTING WORKS.

Written for the MINING AND SCIENTIFIC PRESS
By L. S. AUSTIN.

The Garfield copper smelter is a plant belonging to the American Smelters Securities Co., a subsidiary of the American Smelting & Refining Co. I had visited it in 1905 and again in 1907. On the first occasion it was about ready for operation; on the second, defects inherent to a new plant, were still evident and to be remedied. At a recent visit of the American Institute of Mining Engineers I was gratified to find those defects well overcome, the plant expanded, and basic converting in operation. Too much praise cannot be given to those in close touch with the operating of the works who have contributed to these successful results.

One initial defect was due to an elaborate flue-system which had numerous turns, injuring the draft so that it was difficult to melt the charges in the reverberatory furnaces. To overcome this the converter-flume was led to independent stacks, so that the regular flue-system did not have to take care of it. The flue-system itself was simplified, tightened and shortened, and the catenary flues were strengthened. In consequence the draft was so improved that the reverberatory furnaces were able to attain their full efficiency, a tonnage of 275 tons being handled in 24 hours. These furnaces are operated under forced draft. The fire-box is divided into two parts by a mid-wall so that one-half the grates can be cleaned while the other half continues under pressure.

Another difficulty arose from the defective operation of the conveying system which delivers ore to the sampling mills and to the storage bins. In consequence there were frequent stoppages, and men were set to clean out feed-chutes and to repair defects and break-downs. The Robins Conveying Belt Co. was able to suggest such changes that today this elaborate conveying system is operating smoothly. Its arrangement and operation are described in *Mines and Minerals*, Vol. XIII, p. 305, and in the 'Mineral Industry', Vol. XVII, p. 240, where is to be found an extended description of the Garfield plant.

A third defect noticeable two years ago was the method of charging the blast-furnaces, in which the ore dropped at least 12 ft. from a charging trough set at the charge-floor level. The present arrangement consists in having at each side of the furnace an inclined bottom hopper, as long as the furnace itself, which receives the charge on the side of the track away from the furnace, so that the charge slides instead of falling into the furnace. Where it fell into the furnace it tended to unduly pack the charge and to increase the quantity of flue-dust. It is to be noted that all ore going to the blast-furnaces has been screened to free it from material finer than $\frac{3}{8}$ -in. mesh. This not only lessens the amount of flue-dust, but contributes to the faster running of the furnace, so that a furnace 4 by 20 ft. at the tuyeres puts through 550 to 600 tons per day, a performance

per square foot of hearth area that exceeds the duty at other similar plants in the United States.

Formerly all the ore went through the sampling system. This has been modified by taking out, after coarse crushing at the delivery point from the receiving bins, one-tenth by a large Vezin sampling machine, the rejected portions then going to storage. The converter slag, amounting to 500 to 600 tons per day, is molded in a Kelly slag-casting machine ('Mineral Industry', Vol. XVII, p. 275), and which has proved to be successful partly because of its simplicity, the slag on cooling in the molds being dumped by hand. All this slag is sent back to the blast-furnaces.

Perhaps the most important, bold, and radical change made has been the putting in of a basic-lined converter. This makes probable a step in advance in metallurgy formerly thought impossible. Hickson had experimented with a water-jacketed converter years ago, and had stated that such a device, since it would supply no silica to the charge, could not be used. Later it had been attempted to add the necessary silica by blowing it in at the tuyeres, but this had not been a success. Of recent years silicious ore added to the charge in the converting vessel has assisted in fluxing the iron oxide as fast as it forms, and has thus contributed to saving the lining. Experimental work on the Baggaley converter at Butte, where silica was freely added in the converter, has demonstrated that such external additions may be sufficient. It remained, therefore, to be demonstrated by Brown and Smith at Baltimore, particularly by the latter, that a basic lining could be used, in which the demand of the charge for silica could be met by the addition of a calculated amount of silicious ore. The converting process was thus brought to the point of scientific precision, and no longer involved treatment of a charge of variable composition with dependence on the eye for determination of results.

While the principle of a basic-lined converter is not patentable, application of it, and of details of construction are, and experience is showing where to make them. The converter vessel as used at Garfield, is of the barrel type with a shell 22 to 24 ft. long by 10 ft. diam. In general appearance it is like a Brückner roasting cylinder. This is lined with magnesia brick 18 in. thick at the bottom or lower part, when in the blowing position, and 9 in. above. As much as 2000 tons of copper has been produced with a single lining. The spout, or outlet, for the escaping gases, situated near one end of the shell, shows them to be going off quietly and with the emission of only few solid particles. In fact this gradual escape would seem to indicate slow working. Besides the regular opening is a spout and tap-hole plugged with clay, but which can be opened at the time of pouring the slag. The tuyeres, set 7-in. centres, extend the whole length of the shell. This shell is parted by a longitudinal joint to allow for expansion, with tie-rods which can be let out as the converter becomes heated. Matte of varying grade, say of 30 to 40%, is poured into the converter, and the forming slag, as it accumulates, is poured off from time to time, additions of matte being also made as required. A charge of 40 tons may be poured at a time. The blister-

copper is transferred to a reverberatory furnace where it is poled to enable it to be cast smooth and molded in a Walker casting machine into anodes. Another method of casting, now being tried, consists in using a tilting furnace resembling a barrel converter, large enough to take 50 tons or more of blister-copper. This again is cast in a Walker casting machine. It should be remarked that no particulars have been given of the actual operation of the converter or of the difficulties which have been met.

The Huntington-Heberlein, or pot-roasting, plant has been given up, as it has added to the cost of treatment. In its place the ore is now screened, the fine going to the reverberatories. This roasting operation may be reckoned to cost from \$1 to \$1.50 per ton.

William H. Howard, the superintendent of this plant, is taking much interest in the building and organization of a village of some 80 cabins, and of a large boarding house situated just below the smelting works, and between it and the lake. This is intended for lodging the foreign workmen of the plant, Austrian, Greek, and Japanese. In the village an agent of the smelting company acts the part of mayor, and there is a deputy sheriff for keeping order. Each cabin holds six men, the rent being \$6 per month, or \$1 per man. Each cabin is provided with a stove, and with bunks, and they are much in demand. The boarding house is intended for the Japanese, and consists of two wings, having two-story iron cots, and a central dining room. The house is rented to a responsible man at \$125 per month. This man boards the inmates. Shower baths and wash-basins are liberally supplied for the use of these people, who are a particular and cleanly race. The Austrians are of the three races the largest and strongest physically, and can be depended on for the heaviest work about the furnaces. The Greeks are smaller, weaker, slower, and need close supervision. The Japanese, though a small race, are enduring, intelligent, and anxious to learn. The repair gang at this plant was, for example, made up largely of them.

The Chilean Government has appointed a commission under the direction of the Ministro de Industria y Obras Públicas, at Santiago, to study the question of electrifying the portion of the State railways between Santiago and Valparaiso, a distance of 115 miles. It is proposed to complete the double tracking of this portion of the State railways, for which about one-half of the grading has been completed. It is understood that an offer has been made to put in the installation, including the hydro-electric plant, at a price that would make a handsome saving for the Government in operating expenses over the present steam motive power employed, since coal is expensive. It is only a beginning that will eventually cover the whole Government railway system.

Powdered aluminum is used to an increasing extent in the manufacture of metallic paints and varnishes, its property of not tarnishing making it particularly suitable for this purpose. The paint is valuable in protecting iron, and in rendering wood-work partly fireproof when applied in thick coats.

COPPER IN SOUTHWESTERN WISCONSIN.

Written for the MINING AND SCIENTIFIC PRESS
By G. H. COX.

Since the early days of mining in the upper Mississippi Valley district, when copper was found in paying quantities in the vicinity of Mineral Point, Wisconsin, rumors of the discovery of copper have been so frequent that mining men have become tired of investigating. While copper to the value of more than a quarter of a million dollars has been shipped from the district, there has been no important output for many years, and most reputed discoveries have proved disappointing. Consequently the discovery this summer of a workable deposit in this district is of exceptional interest. I recently examined a copper prospect, situated in section 36, T. 2 N., R. 3 E., about five miles in a direct line from Gratiot and eight miles from Shullsburg, which shows by the appearance of the dump that an unusual deposit of copper has

Copper Prospect. Gratiot, Wisconsin.

been found. A number of shallow test pits have been sunk to permanent water level, a depth of 18 to 28 ft., and the ore extracted therefrom was to be seen upon the dumps. The ore consists mainly of chalcopyrite, chalcocite, malachite, cuprite, azurite, bornite, and some small pieces of native copper. Apparently the original mineral was chalcopyrite. The alteration of this has formed the secondary minerals and at the same time increased the percentage of copper. Assays yielding 40% copper are claimed for the best ore, and at the present time there is a car of ore on the dump which will probably average between 20 and 30%. After sinking through about three feet of soil, loose pieces of ore were found scattered over the surface of the limestone about the tops of a series of 'ten o'clock' crevices. Shafts had been sunk upon two of these crevices, about ten feet apart, both in good ore. The width of the crevices has not been definitely determined because of the decomposed condition of the rock at this place. One is said to be four feet across but it is clear that a part of this is due to solution later than the deposition of the ore, as the latter is found in loose chunks in a soft, sandy, dolomitic mass. However, the original crevice must have been at least two feet wide as one piece of ore weighing 600 lb., and a number of others weighing 200 to 300, were extracted and are now to be seen at the prospect. Nothing is known about the distance the orebody extends along the crevices be-

yond perhaps 150 ft. It is claimed that pieces of copper ore have been found at intervals along the strike of these crevices for a distance of three miles northwest and one-half mile southeast. Vertically the ore has been opened to a depth of 28 ft. A 16-ft. rod can be pushed down its full length into the crevice below this level, showing that apparently the crevice extends for at least this distance below. It was not possible in the time available to determine the exact stratigraphic position of the deposit, but seemingly it is in the lower portion of the lower non-flinty beds of the Galena dolomite (Ordovician). It seems probable that the oil-rock occurs within 10 ft. of the bottom of these holes, and if so, the open condition of the crevice indicates that the ore extends down into the Plattville limestone.

The occurrence of pyrolusite, and wad, in pieces 6 to 8 in. thick, is both extraordinary and peculiar, though of no known economic significance. The statement of the miners that steel tools placed in the spring water, which issues from one of these crevices, are soon coated with a copper precipitate is important, if true. The flow is quite strong and a solution of such strength would be the best evidence available in favor of the occurrence of a large deposit of copper close at hand. The deposit is exceptional in both the occurrence of copper and manganese. It is isolated, there being no mines within a number of miles. It further complicates the matter of a satisfactory explanation of the origin and occurrence of the ores of the district.

MAGNETIC SEPARATION.

The first application of magnetic separation was in the concentration of certain iron ores, principally magnetite, in order to produce a product richer in iron, and also to eliminate certain minerals that contained elements injurious to the metallic iron. The next application was to other iron ores, such as limonite, hematite, and siderite, after they had been given a preliminary roasting to convert them into the magnetic oxide. The next step was in the separation of magnetic iron particles from certain copper, gold, and zinc ores, either before or after roasting. For many years this was the only application made of magnetic separation. It was found, however, upon experimenting with an electro-magnet with a higher intensity, that other minerals were subject to magnetic attraction, and that it was possible to separate minerals into more or less pure products by varying the intensity of the magnetic field. Thus, it has been possible to adapt this method of separation to ores containing iron or manganese which are only weakly magnetic. As is well known, steel bars may be magnetized, and they will retain more or less of this magnetism indefinitely, while bars of softer wrought or cast-iron may be magnetized by means of electric currents in surrounding coils of insulated copper wire. These iron bars do not become permanent magnets, but form electro-magnets as long as the current flows around them. They can be given a greater and more constant strength than can be given to the permanent steel magnets, and for this reason, in nearly all of the magnetic processes, electro-magnets are used instead of the field magnets.

MODERN PRACTICE OF ORE-SAMPLING.

By DAVID W. BRUNTON.

*From the old-fashioned 'grab-sample' to the modern timing device, which takes a machine-sample with mathematical precision, there is a wide gap which was only crossed by many years of toil and unremitting endeavor. Even today 'grab-sampling' is still practised, sometimes to afford the unscrupulous mine-promoter a basis for fairy tales with which to entrap the too gullible investor, and often by milling and smelting companies to determine the amount of moisture in custom ores. The latter practice is almost as reprehensible as the former, and it causes more trouble and ill-feeling between seller and buyer than all other factors put together. Samples for the determination of moisture should be taken with as great care as for the determination of metallic content, and in order to avoid the extra expense of a separate operation, moisture-samples should be taken from the sample-safe. As the sample reaches the sample-bin in a smaller stream and by a more circuitous route than the 'reject' travels in its path to the outgoing car, it loses more moisture on the way, and a constant should be added to compensate for this difference. Carefully conducted experiments have shown that the difference in loss of moisture between the two routes does not exceed 10% in summer and 7% in winter.

Shovel-sampling, another archaic method which is still used in some localities, consists in throwing out from the car or wagon every third, fifth, or tenth shovelful for a sample. As the portion of the pile from which the sample is taken is entirely at the discretion of the operator, the process would be more properly named fifth-shovel selection than fifth-shovel sampling.

Thirty years ago Cornish quartering was the almost universal method of sampling in use, and it is still employed to a considerable extent in cutting down machine-samples and in mine examinations where no machinery can be had. When properly carried on with skill, care, and common honesty, fairly good results may be obtained by quartering, but between the possibility of accidental mistakes and the opportunities which it affords for skillful and unscrupulous operators to manipulate the sample, it has fallen almost into disuse, and should have been completely abandoned long ago. The inherent defect of this system lies in the fact that piling a lot of ore in the form of a cone does not mix it, as the advocates of this system claim. Dropping shovelful after shovelful of ore on top of a cone, instead of building up a homogeneous pile, actually produces a very perceptible sorting action, whereby the fine builds up where it falls on the centre of the cone and the coarser particles roll outward and down the sides. The most uniform and best results are obtained by coning around a rod.

The most ingenious plan adopted by unprincipled operators for 'throwing' the sample, and one which is so difficult to detect that it can be carried on directly under the eyes of a skilled observer without

detection, is what is known as 'drawing the centre'. The cone is started on the floor, without any rod to determine the position of the centre. The operator in charge of the work, in dropping his shovelfuls of ore on the top of the cone, does it in such a manner as to draw the centre of the cone imperceptibly in a certain direction, so that by the time the entire sample is piled and ready for spreading, the apex of the cone is several inches, we will say, to the southwest of the original centre. The ore may now be spread as usual with shovels or with a board, and cut and marked into quadrants by steel blades in alignment with the four points of the compass. By rejecting the northwest and southeast quarters an excess ratio of the fine is eliminated, and since this is generally the richest ore, the metallic content of the two retained quadrants will be somewhat less than the average of the original pile. Suppose a 2000-lb. lot is to be reduced to 62.5 lb., it would mean that the 'quartering' (really halving) would have to be repeated five times, and if at each stage the sample taken represented 98% of the actual value of the cone, the final sample would only give 90.3% of the true value of the cone, as shown in the following tabulation:

| | Original lot. | 1st cut. | 2nd cut. | 3rd cut. | 4th cut. | 5th cut. |
|---------------------------|---------------|----------|----------|----------|----------|----------|
| Weight, pounds | 2000 | 1000 | 500 | 250 | 125 | 62.5 |
| Percentage of true value. | 100 | 98 | 96 | 94.1 | 92.2 | 90.3 |

The irregularities in the results obtained by Cornish sampling, together with the cost of operation and the amount of room required, soon brought about what is known as 'split-shovel' sampling, in which the ore is thrown from a broad shovel, handled by one operator, upon a narrow U-shaped shovel, held by another workman, usually directly over a car or wheelbarrow. This method, while it requires two men to do what normally appeared to be the work of one, was cheaper than Cornish quartering, but it proved no great improvement over the latter in point of accuracy, since carelessness in almost any direction interferes seriously with results.

The earliest attempts at mechanical sampling were made by subdividing a falling stream of ore; a process based on the supposition that an ore-stream could be mixed so as to be perfectly homogeneous. Both analysis and experience have shown that this ideal condition is impossible, and mechanical devices for taking a portion of the ore-stream all of the time have been almost entirely displaced by machines designed to take all of the ore-stream for a portion of the time. It is not practicable to produce a stream of ore which shall be continuous in value through every part of its length any more than it is possible to produce a stream of ore that is constant in value throughout its width; but by taking a small sample entirely across a falling stream at short intervals it is found that, while no single cut would give an exact representation of the composition of the entire lot, the average of thousands of these small samples is so nearly correct that results can be duplicated within very narrow margins, or, in other words, that individual errors are balanced. This was not the case with the devices used for taking a portion of the stream all the time, since the errors due to feed, inclination of spouts, or wear on the bottoms of

*Read before the Spokane meeting, September 1909, Amer. Inst. Min. Eng.

the spouts, are constant, and do not vary during the time the samples are being taken.

Almost coincidental with the discovery of the fact that accurate samples could be obtained by taking all of the stream for a portion of the time, came a considerable improvement in rock-crushing machinery, so that the modern engineer has a much better opportunity to construct a satisfactory plant than the builder had 20 or 30 years ago. Not only are the rock-breakers and rolls of today greatly improved in design, but the manufacturers have availed themselves of modern cheap steel to give all parts an excess of strength over any possible strain, while the use of alloy-steels for the wearing surfaces permits the machines to be kept in much better repair, and requires fewer stoppages for renewals. For sampling-work, crushers and rolls can now be had which are almost as well made as the ordinary steam engine, and so designed as to give complete accessibility for renewals and for cleaning.

Gyratory breakers of the Gates type have the advantage of delivering a uniform product, and in crushing ores that are hard and dry this type forms

newer devices, although the modern sample-grinder is much heavier, better built, and more easily cleaned than its predecessors.

The first mechanical samplers were imitations of Cornish quartering, the 'whistle-pipe' being the most common type. With ore finely crushed, fairly dry, well mixed, and entirely free from strings and rags, and with the dividers new and exactly centering the pipe, fairly good results could be obtained by this method; but as these conditions never existed in practice, and as the edges of the cutters wore rapidly, thereby moving the dividing line back from the centre, this form of sampling machine was soon discarded, and I believe has now fallen into absolute disuse.

Following the whistle-pipe sampler came the various forms of mechanical split-shovels; but as there was no place in a spout, no matter how wide or carefully built, where a single U-shaped spout could be placed to take a sample which would represent the entire width of the stream, this form also was soon discarded.

More recently this splitter has been revived by an

Fig. 1. Delivery Spout of Charles Snyder Sampler. Cutting Edges Radial.

Fig. 2. Delivery Spout of Vezin Sampler. Cutting Edges Radial.

Fig. 3. Cutting Edges Not Radial.

by all odds the best initial crushing machine; but with ores that carry wet clay, slate, or other substances which will 'pack', it is necessary to use a swinging-jaw crusher, preferably of the Blake type. Rock-breakers may be set to crush to any desired fineness, but it has been found that too great a reduction in the size of the product materially reduces the capacity. In large crushers it is not usually advantageous to attempt to crush below 2-in. size.

First-class rolls are now always belt-driven, which eliminates the noise and danger attending the operation of the old-fashioned trains of gears. The best practice in roll crushing is to crush not smaller than half the diameter of the particles fed to any given machine. This rule gives approximately the maximum crushing capacity with the minimum production of fine and the lowest expenditure for power and metal. Rolls require a steady feed, and one which is uniform across the entire width of the shell; consequently nearly all modern rolls are equipped with some feeding device. In sampling mills the shaking tray is generally used on account of the ease with which the rate of feed can be inspected, and the great facility with which such feeders can be cleaned after each lot of ore has been run.

For fine-grinding machines, the coffee-mill type still successfully holds its own against most of the

adaptation of the ordinary hand-operated splitter in which numerous small spouts are so arranged across the entire width of a larger one that the main ore-stream is divided into a great number of smaller ones, the even numbers being deflected to the right and the odd numbers to the left. This plan works well on the first division, but as it effects a reduction of only 50% in the volume, the operation must be carried further, and the streamlets forming the sample centered into a broad stream, which, in turn, passes over another set of splitters, the operation being repeated as often as necessary to reduce the sample to the desired size.

The latest types of samplers are usually known as 'time-sampling machines', from the fact that they deflect the entire stream into the sample compartment for a varying portion of the time, depending on the percentage of sample required. Treating the falling stream as a ribbon, they cut sample sections directly across its entire width, these portions varying in shape and size with the mechanism employed. Of the many types that have been invented and patented, only three, the Charles Snyder, the Brunton, and the Vezin, have come into general use.

Both the Charles Snyder and the Vezin samplers have sector intake spouts revolving on a vertical axis, the only difference between the machines being

that the delivery spout in the Snyder sampler is an annular quadrant, *D*, in Fig. 1, while the Vezin delivery pipe is either square or rectangular, *E*, in Fig. 2. In order to take a correct sample the cutting edges of the sector intake spouts on both of these machines must be exactly radial, as shown in Fig. 1 and 2, otherwise they will include more degrees of arc at one part than at another; and consequently the percentage of sample taken from all parts of the delivery pipe will not be the same, as is shown by Fig. 3, in which the cutting edges are not radial to

feed to a sector intake this sorting action does not seriously affect the sample if the delivery spout is perfectly level and free from ridges which would deflect the particles across the stream; but with a radial feed used, as shown in Fig. 2, and the intake sample-spout edges not radial, as shown in Fig. 3, it will readily be seen that a larger proportion of coarse than of fine is taken into the sample.

Since the cutting edges of this class of samplers are necessarily maintained in a horizontal position, they are liable to become overhung with strings, burnt fuse, and drill-rags, which the mill attendants often endeavor to remove by pounding the sides of the spout while the machine is in motion, thereby distorting the form of the intake spout considerably from a true sector, and rendering it impossible to obtain a correct sample unless the delivery stream is perfectly homogeneous, which is never the case. The great length of the radial edges of the sector intake spout renders them, of course, peculiarly susceptible to be thrown out of alignment, and manufacturers of this class of machines should do something to shorten the length of the radial edges, or stiffen them to prevent accidental distortion. At first sight it might be thought that this could be accomplished by reducing the size of the sector, but experience has shown that the width of any spout delivery, or intake should be something more than three times the greatest diameter of the coarsest particle passing through it; otherwise a bridging effect occurs which affects the flow and often chokes up the spout. It is, therefore, good practice to make the width of the feed and intake spouts four times the diameter of the coarsest particles passing through them.

The Brunton time-sampler oscillates in a vertical plane through an arc of 120° instead of revolving in a horizontal plane like the sector-intake machines, an arrangement which permits the use of a rectangular intake spout with cutting edges so short that accidental distortion is impossible, while the tilting of the cutters at the end swing materially assists in dislodging any rags or strings which may have fallen on the cutting edges. This construction requires less head-room than any other

system, which effects a great saving in the cost of mill-construction, since it not only reduces the necessary height of the building, but shortens all spouts and conveyors. One advantage in the use of this machine is that, as the discharge of the ore from the sampler is assisted by centrifugal force instead of being retarded thereby, as is the case with all sector machines, it can be run at a much higher rate of speed, thereby increasing the number of samples per minute. This arrangement insures greater accuracy, since the more samples which can be cut from the falling ribbon without 'batting' the ore too vigorously with the sides of the cutters,

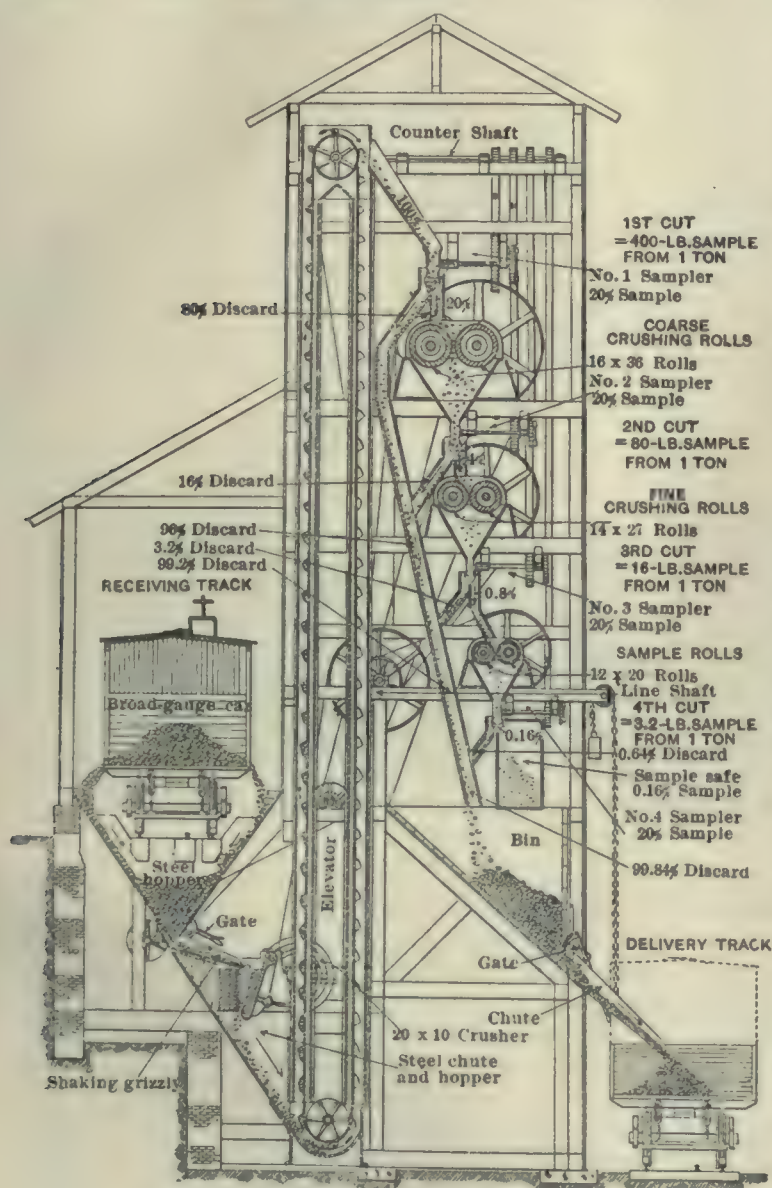

Fig. 4. Taylor and Brunton Sampling System.

the better are the chances for obtaining an exact average of the stream.

While there seems to be a general impression among mining men that high-grade ores are more difficult to sample correctly than those of low grade, there is no reason for this assumption. The difficulty of sampling accurately increases directly as the difference between the value of the highest and the lowest-grade material contained in the lot, and is at its maximum when the metals are carried in large masses of metallics or crystals of very rich minerals occurring in barren rock. If we imagine a lot, for instance, of Cripple Creek ore, composed entirely of barren gangue and one solitary piece of calaverite, it would be manifestly impossible to sample such a lot of ore without crushing, since in any subdivision either the sample or the reject would contain all of the mineral. Suppose this lot to be subjected to a slight crushing and the solitary piece of mineral broken into three fragments, then dividing the lot into halves would at the best throw 50% more value into the one half than into the other; it is therefore clearly manifest that in order to obtain a sample which shall correctly represent this or any other lot, it is necessary to crush it to such a degree of fineness that one particle more or less taken into the sample shall not materially affect its metallic content. In other words, the maximum error is determined by the ratio of the weight of the largest particle of metal or high-grade mineral to the weight of the entire lot. At this point another condition must be considered. In any lot of ore it is easy to see that the chances of finding a full-sized piece of the highest-grade material would be much greater on a lot of ore crushed to 0.25-in. cubes than in a lot crushed to 1-in. cubes, therefore accuracy demands that the ratio between the weight of the largest particle and the entire lot shall increase directly as the fineness.

In this particular, practice and theory are in complete accord, and all of the latest and most improved mills practice alternate crushing and subdivision from the coarsest size down to the finest. It is customary at each successive stage to reduce the diameter of the coarsest particles one-half, thus decreasing the volume to one-eighth, or 12.5%. The usual sample taken at each successive stage is 20%, so that while the size of the particle at each step has been reduced 12.5%, the amount of sample taken is 20%, consequently the ratio between the weight of the largest particle and the weight of the sample rises steadily from the beginning of the series of operations to the end, thereby meeting the conditions theoretically necessary to an accurate determination of value.

An ideal sampling mill, where the situation and nature of the service will permit this form of construction, is shown in Fig. 4. This plant is entirely automatic, and when the ore is received in hopper-bottom cars no manual handling is required at any stage, while the sample is automatically delivered into a locked steel safe. To simplify the drawing, the roll-feeders have been omitted.

To show how closely results between different mills and repeat-sampling in individual mills may be made to check, the following example may be cited:

SAMPLING RESULTS, TAYLOR & BRUNTON SAMPLING CO., CRIPPLE CREEK, COLORADO.

The most convincing tests of correct valuation in ore-sampling are those, such as the one cited, in which numbers of small lots are bought and paid for individually, and stored for a considerable time, until a sufficient quantity of ore has been collected to form one large lot. When this period arrives the individual lots are not mixed, but run through the mill in succession, and it is usually found that the mechanical sample of the mixture agrees with the calculated average as determined by the values in the original purchases as closely as the best control assays. The small lots when originally received, sampled, and purchased are coarse and generally wet, but when run through the mill the second time they are both fine and dry, giving thereby the greatest possible dissimilarity in conditions of size of particles and moisture content. The excellent checks obtained on this class of work show conclusively that with 'time-sampling' the results obtained are in no way affected by the physical conditions of the ore, and may be implicitly accepted as correct.

The art of sampling has now reached a stage where a standardization of methods is both desirable and possible, and it is to be hoped that the Mining Congress, or the proposed Bureau of Mines, will take the matter under consideration

CONSOLIDATION OF MOTHER LODGE MINES.

Written for the MINING AND SCIENTIFIC PRESS
By W. H. STORMS.

Few gold mines are better known to the world than the Keystone at Amador City, Amador county, California, and few have a more enviable record of production. The Keystone became famous by reason of its long continued and heavy output of gold, its total production approximating \$17,000,000 since 1851, when the first claims were located. At that early day adventurers from every land and of every conceivable character had flocked in thousands to California, where, with frantic energy they began tearing down the 'everlasting hills' and digging into the rocks in search of fortune. Among this motley mob of pilgrims, a number of men, ministers of the gospel, who knew nothing of mining, but who in this respect were no worse off than the thousands of other adventurers around them, located a claim on the south side of Amador creek, up on the hillside, where massive slabs of greenstone protruded from the ground like huge tombstones in an ancient

adjoining property was acquired and added to the consolidation, and soon thereafter the Keystone began to pay, becoming in time one of the most important mines in the State. Its career of success has extended over an unbroken period of nearly 60 years. Notwithstanding this long-continued period of prosperity the Keystone is still a comparatively shallow mine, though its development is probably in excess of a total length of 12 miles. Much of the work of the earlier years is now caved, and is inaccessible. There have been sunk on the property not less than 6 shafts, only 2 of which are deep—the Patton shaft, down 1573 ft., and the South shaft with a depth of 1200, both being inclines. The Patton is the main working-shaft, and is the only one at present open from top to bottom. Its incline depth is 1573 ft. (1200 vertical), which is only one-third the vertical depth of the Kennedy vertical shaft, near Jackson, a few miles to the southward. The South and Central Eureka and the Argonaut mines are each about twice as deep as the Keystone, and the veins show no signs of weakness, so it will be understood that the prospects for the future of the Keystone in

Keystone Mine, Amador, California. Property of California Consolidated Mines Company.

graveyard. Running along the edge of the greenstones was a large vein of stained quartz, separating the greenstone from the slates which lie to the west of it. The miners called their claim the Spring Hill, so named because of the occurrence of a spring up the hill issuing from the vein. A second claim adjoining was taken by other men, who named it the Geneva.

One of the first mills to be built on the Mother Lode in California was that on the Spring Hill claim; but owing to its rude construction and to the miners' lack of knowledge of its proper operation, it proved a failure at first. Later, however, when improvements, suggested by experience, were made, things went somewhat better. Several custom mills, in which ore from various mines was crushed and amalgamated, were built in the neighborhood, but these early operations were far from satisfactory. Believing that by combining their efforts economy would result, the Spring Hill and Geneva claims were consolidated.

Meanwhile the Keystone claim had been located down in the gulch to the westward of the Spring Hill and Geneva, and the owners of the Keystone, at that time having more money, if less ore, than their neighbors, bought the former property, and it was called the Consolidated Keystone mine. Later other

greater depth are attractive, to say the least.

The Keystone mine is not developed, as many infer, on a single fissure, but consists of a number of fissures, or veins, some of them wholly in black clay-slate, some at the contact of the clay-slate and greenstone schist, and others in the greenstone country. Generally in these mines the greenstone in the vicinity of the fissures has been rendered schistose on one or both sides of the fissure. Often the schists approach a slaty cleavage, are black and lustrous, and sometimes difficult to distinguish from the clay slates. The latter, when not adjacent to a vein, are generally of exceedingly fine texture, finely laminated, hard and brittle, and usually may be split with facility to the thinness of sheets of paper. The schists split less freely, and can seldom be divided into sheets as thin as the clay-slates. Payable veins occur in both formations in the Keystone mine, as well as in the other mines of the Mother Lode in Amador county.

A few months ago the California Consolidated Mines Co., was organized to take over and operate under a single management the Consolidated Keystone mines at Amador, and the Wildman-Mahoney mines, another large property at Sutter Creek, together with a number of intervening properties. When the entire consolidation, as contemplated, has

been effected it will become one of the most extensive and valuable gold mining properties in the world. There are on these consolidated mines at present 140 stamps, in three mills, all of which, except 20 in the south end of the Keystone, are of light weight. The equipment generally is of ancient pattern, far less efficient than the modern type of gold-mill.

The California Consolidated Mines Co. has ambitious plans, but these are only such as are essential in the conduct of large operations along modern lines. They include repairing the Keystone incline shaft, and continuing it to 2500 ft., for which purpose new steel ropes were put on a few days ago; the sinking of three and probably four deep vertical shafts, at suitable sites along the Lode, one of which, the Emerson at Sutter Creek, is already down 620, and another, 1000 ft.; the construction of two or more large, modern, heavy mills aggregating 500 stamps; the building of a system of local railroads for ore transportation; the extension of the main line of the Amador Central railroad to the vicinity of the mines at Sutter Creek and Amador City, and numerous other betterments both above and below ground.

There are immense ore reserves in both the Keystone and Wildman-Mahoney mines. Much of this ore is low-grade, but will yield a substantial profit when the contemplated equipment is supplied. In addition to these reserves are smaller veins of higher grade ore, on which the mills are operating at present. There is considerable unexplored territory in both the Keystone and the Wildman properties, while the possibilities of greater depth in these mines, by comparison with the ore-occurrence as developed in the deep levels of neighboring mines, is very great. Some of the best mines of Amador county only became largely profitable below 1000 ft. from the surface, while the Keystone and Wildman are each but 1200 ft. deep vertically, and to that level have produced over \$20,000,000. What lies below is wholly unknown, but I believe it to be the best undeveloped mining ground today on the Mother Lode of California.

On the Mother Lode in Amador, the principal formations are slates, schists, and greenstone. The true slates are argillaceous; the schists and gray-slates are magnesian. These latter, often blackened by carbonaceous matter, are the result of the shearing, and to some extent the chemical alteration, of the greenstones. The greenstones are in part massive intrusions, and have been variously called 'diabase', 'andesite', and 'meta-diasite'. They are basic rocks, frequently olivine-bearing, with abundant augite. Their green color is due to the dissemination of minute particles and threads of chloritic and hornblende mineral (uralite probably). Other phases of the greenstones are masses of ancient breccia, or agglomerate, cemented in a finer ash into a hard, usually dense, and extremely tough rock. Still other masses comprise vast accumulations of ancient tuff, also now rendered dense and hard by metamorphosing influences. All of the greenstones, whatever their origin, on this lode, are found deformed, sheared, and altered into schistose and slaty rocks,

which are generally designated amphibolite schist.

Gold-bearing fissures are found in all of the rocks above described. Some of the veins are beautifully banded, and this type is frequently rich in gold. Other veins, particularly the larger ones in the schists and breccias, are massive, with no evidence of banding except occasionally along the edges of the mass. These orebodies, though generally of lower grade, are nevertheless sometimes surprisingly rich in gold. It is not uncommon to find rich pockets in these schists, the Keystone mine having become noted for them. Occasionally, as in the Mahoney mine, at Sutter Creek, sulphide ore of surprising richness is found in these veins. In the instance mentioned, solid sulphide ore worth over \$20,000 per ton was discovered in a vein in the schists in that mine. It occurred as a small vein about 3 in. wide in a larger vein of unusually good ore.

Mining on the Mother Lode in Amador county is in a more prosperous condition than for many years. Two of the old mines which had long been operated at a loss have within the year been placed on the dividend list, and this is what counts. I refer to the South Eureka and the Bunker Hill. The former is a mile south of Sutter Creek, the latter is the second property north of the Keystone. Other important developments are looked for in the mines of this vicinity, and I feel safe in predicting a great increase in interest in mining on this famous belt within the next 12 months. Among the latest developments are the Original Amador, adjoining the Keystone on the north; the resumption of work on the Muldoon property, adjoining the Argonaut on the south, and now known as the Kennedy Extension gold mine; the Treasure, formerly the Hazard, which is situated between the Bunker Hill on the south and the Fremont Con. on the north, and in the vicinity of Plymouth, the preliminary development of the veins in what is known as the Orr ranch, by Webb Smith, superintendent of the Kennedy mine, and his associates. Each of the properties mentioned has good prospects, and all who are familiar with the Mother Lode expect to see valuable mines developed at the places mentioned.

CHART OF IGNEOUS ROCKS.

Prepared for the MINING AND SCIENTIFIC PRESS
By STUART CROASDALE.

A few years ago Scott Turner published in the MINING AND SCIENTIFIC PRESS a chart of the igneous rocks, which was a simplified form of an elaborate tabulation by F. E. Wright.

I submit herewith a still more simplified chart, arranged from F. W. Clarke's 'Data of Geochemistry',* which may constitute a valuable accompaniment for Mr. Turner's chart, since it shows more clearly the relation of the rocks to each other. Those who wish to carry these charts in their note books will find that the full page of the MINING AND SCIENTIFIC PRESS can be reduced by photography to 4 by 6½ in. and still be easily legible. Prints of this size may be made from the negative and pasted in note books.

*Bull. No. 330, U. S. Geol. Survey.

| IGNEOUS ROCKS. | | |
|--|--|---|
| PLUTONIC. | INTERMEDIATE. | ERUPTIVE. |
| GRANITE-RHYOLITE SERIES. | | |
| <p><i>Granites.</i></p> <p>Holocrystalline. Dominant minerals: quartz and alkali feldspar (orthoclase or microcline). Subordinate minerals: muscovite, biotite, hornblende, etc.</p> <p><i>Aplite</i>, a granite with quartz and feldspar only.</p> | <p><i>Quartz Porphyries.</i></p> <p>Intermediate between the granites and rhyolites.</p> | <p><i>Rhyolites.</i></p> <p>Eruptive equivalents of the granites with same chemical composition. Quartz and feldspar, predominating minerals. Commonly contain more or less undifferentiated glass.</p> <p><i>Obsidian</i>, is the wholly vitreous variety of rhyolite.</p> |
| The difference between granites and rhyolites are structural and genetic; chemically and magmatically they are the same. | | |
| SYENITE-TRACHYTE SERIES. | | |
| The Syenite-Trachyte series differs from the Granite-Rhyolite series in being free, or nearly so, from quartz. All of these rocks contain principally alkali feldspars, with subordinate femic minerals, and often alferic species, such as hornblende, mica, etc. | | |
| <p><i>Syenites.</i></p> <p>Resemble the granites in their deep-seated plutonic origin and in being holocrystalline.</p> | <p><i>Syenite Porphyries.</i></p> <p>Intermediate forms between the syenites and trachytes, analogous to the quartz porphyries.</p> | <p><i>Trachytes.</i></p> <p>Like the rhyolites, they are eruptive rocks.</p> |
| NEPHELITE SERIES. | | |
| <p>These are transition rocks from the syenites and trachytes proper, to the phonolites and nepheline syenites. They occur in plutonic, intermediate, and eruptive groups like those above. Quartz is absent, and lenads, or feldspathoids (feldspars deficient in silica) replace the feldspars to a greater or less extent.</p> <p>Phonolite is commonly made up of orthoclase, nephelite, and pyroxene.</p> | | |
| MONZONITE GROUP. | | |
| <p>The Granite-Rhyolite series of rocks, and the Syenite-Trachyte series also, are defined by the predominance in them of alkali feldspars, and commonly of orthoclase.</p> <p>The Andesite-Diorite series (see below) is characterized by plagioclase feldspars.</p> <p>Between these series are all sorts of gradations known as <i>monzonites</i>. All these rocks carry orthoclase or anorthoclase and plagioclase in approximately equal amounts, with or without quartz, and with smaller amounts of the ferromagnesian silicates.</p> <p><i>Quartz Monzonite</i> corresponds with granite. <i>Latite</i> is an effusive equivalent, intermediate between the trachytes and andesites.</p> <p><i>Monzonite</i> corresponds with syenite.</p> | | |
| ANDESITE-DIORITE SERIES. | | |
| From the monzonite group to the quartz-diorites the gradation is very slight. These rocks, which mark the persilicic end of the Andesite-Diorite series, are characterized by quartz, with plagioclase as the prevailing feldspar, and with subordinate amounts of ferric minerals. They correspond to granite and rhyolite in the Orthoclase series. | | |
| <p><i>Quartz Diorites.</i></p> <p>Plutonic or deep seated like granite.</p> <p><i>Diorites.</i></p> <p>Plutonic equivalent of andesite. A granitoid rock consisting chiefly of plagioclase with either biotite or hornblende, or both. Many diorites carry pyroxenes and shade into gabbros.</p> | <p><i>Diorite Porphyries.</i></p> <p>Analogous to the quartz porphyries.</p> | <p><i>Dacites.</i></p> <p>Eruptive like rhyolite. Dacite is a quartz andesite.</p> <p><i>Andesites.</i></p> <p>Poor or lacking in quartz. They form a group of rocks parallel to the trachytes, and contain plagioclase as a principal constituent, with subordinate biotite, hornblende, and pyroxene.</p> |
| GABBROS. | DIABASE. | BASALTS. |
| <p>Granitoid equivalent of the basalts. Consist mainly of plagioclase and pyroxenes, with various admixtures of other minerals. A large family of rocks, varying from almost entirely plagioclase to near pure <i>femic rocks</i>, such as pyroxenites, hornblendites, and peridotites.</p> | <p>Intermediate in texture between the granitoid gabbros and the basalts. Consists chiefly of plagioclase, augite, magnetite, and sometimes olivine.</p> | <p>Contain more femic minerals than andesites. Plagioclase, pyroxene, magnetite, and often olivine are principal constituents. Hornblende rarely occurs.</p> |

COMMENCEMENT ADDRESS.

By JOHN HAYS HAMMOND.

*I am often asked what I regard as the essentials of professional success in mining. First and above all other considerations, I would place the possession of character. An honest, clean cut, straightforward, conscientious young fellow, ambitious, persevering, and last, but by no means least, level-headed, would in my judgment possess 75% of the essentials of success; while in relative importance I would not attach more than 25% to the possession of a technical education. And I say this without in any degree depreciating the inestimable value of a technical education. In the mining profession the adage, 'Make haste slowly' applies with unusual force. The tendency in recent years on the part of the mining engineer has been to neglect that practical experience so essential to the completion of its professional equipment. It is customary for the young engineer—after spending a few years in sampling mines—to enter the field as a 'mining expert'. The inevitable result is that he never acquires the practical knowledge that comes from years of experience in mines, mills, and smelters—knowledge indispensable to his subsequent work as an expert. There is today a scarcity of competent mine managers. The old hard-headed practical mine manager, who has worked up from the bottom and has acquired a thorough knowledge of all the phases of the mining business from actual experience, has been superseded by the graduates of the mining schools, who, in many instances, after but little experience step into the management of a mining company. And yet it is true that never before has there been found so highly competent mine managers as today. These are the men, who, after having received their technical training in the schools, have, like the old time practical miner, acquired an intimate knowledge of the subject through years of experience in subordinate positions.

Formerly the report of a mining engineer or expert was confined to the geological and other cognate features of a mining enterprise; today, the engineer is expected not only to embody in his report information on these subjects, but to give his opinion as to whether the property offered for sale is worth the price asked for it. He is indeed an engineer of but limited usefulness if he does not go farther professionally than to present a purely technical report on subjects submitted for his consideration. While the same responsibility obtains as formerly, in the solution of the technical problems, the expert has also to deal with the financial and commercial aspects of the problems. Moreover, if he recommends the purchase of a property he incurs a certain moral responsibility for its efficient management, inasmuch as his professional reputation depends on the realization of his predictions as to the outcome of his clients' investment. For this reason the engineer sometimes passes from the role of an expert to that of a consulting engineer.

For many years I have strongly advocated the

evolution of the engineer and expert into the 'mining man'. There is now interposed between the mining engineer and the investors a class of men known as promoters. To what I regard as the intrusion of these mine promoters I ascribe the failure of many mining enterprises. These promoters are, as a rule, men who have but a superficial knowledge of mining. Indeed, many of them have been failures in other walks of life, and have gone into this vocation because of the fact that it presents unusual opportunities of getting rich quickly. Not only are the majority of men in this class incompetent and ignorant but they are often unscrupulous. I recognize, of course, that there are among them many men who have a fairly good knowledge of practical mining and who possess undoubted integrity. I should like, however, to see the mining engineer acquire such a knowledge of business methods as to enable him to take the place of the mine promoter. This would insure mining investment upon a more conservative basis, thereby greatly minimizing the risk. To the engineer who in that way becomes the mining man to whom I have referred, an interesting and remunerative field would be opened.

I have noted of late, especially on the part of young mining experts, the exhibition of a sense of pride in having 'turned down' a great number of mining propositions. Now, I do not wish to encourage any zeal on your part to make mistakes, but I do wish you to base your claim for merit, not upon the negative virtue of not making a mistake by turning down properties, but upon the successful foundation of mining enterprises through your professional advice and direction. Do not be 'from Missouri' on every mining proposition presented to you. On the other hand, be not over-credulous and an easy mark.

As the President of the American Institute of Mining Engineers, I delivered an address about a year ago on 'Professional Ethics'. Some prominent members have dissented from my views on the subject and have reproached me for wishing to inject into the sphere of the mining engineer what they regarded as too much commercialism. Nevertheless I continue to regard mining as aimed to make a profit in the exploitation of mineral deposits, and I do not believe that the function of the engineer should be limited to the consideration of the academic features of mining problems. In the address, I referred to the propriety of the engineer making a report for the vendor of the mining property. Such practice has been, I know, generally condemned. But, a little reflection will show that the condemnation is not warranted, for it is neither wrong nor unreasonable that the owner of the mineral properties who desires to present such a statement of its nature and probable value as will insure the attention of contemplating purchasers, should, for the purpose, secure the assistance of one who knows how to make such a statement intelligently and in scientific language. Such a report should, however, be plainly designated a 'vendor's report', and the young engineer in making the report should use every precaution against the illegitimate or misleading use of its statements.

There arises also in this connection the question of the acceptance of contingent fees by the engineer. It

*Abstract from *Quarterly of the Colorado School of Mines*, delivered at Golden, Colorado, May 28, 1909.

seems to me that an expert of established and unimpeachable reputation is perfectly justified in recommending the purchase of a property and accepting compensation from the promoters, provided first, and without qualification, that full publicity be given to the nature of his connection with the enterprise, and second, that his compensation be contingent not upon the successful sale of the property, but upon the subsequent success of the undertaking. The acceptance of commissions from the sales of machinery, is another subject embraced in professional ethics. In many instances of a similar nature, affecting other professions, this practice seems to be established and condoned, if not avowedly justified; but in the mining profession I can see no justification whatsoever.

A young mining engineer should be as loyal to the corporation which he serves as to any individual. If he 'cannot stand for' the policies or practices of his employer, it would be the straightforward course to seek employment elsewhere. To retain the respect of his subordinates and thus assure the team work that wins in industrial undertakings, as well as on the athletic field, is quite as important for the engineer in charge of operations as it is to inspire the confidence of his employers. To be what is called a good mixer is an important qualification for the engineer. This is largely a hereditary trait, it is true, but the tendency to become exclusive and self-complacent can at least be overcome. Most valuable information as to mining developments and conditions in a new district can be acquired second-hand from even the unlettered stage-driver of the district, and many an important hint is dropped in a smoking car.

There are two distinct classes of mining ventures with which the engineer has to deal in his professional capacity. The first is the so-called 'gilt-edged' mining investments. Here the engineer exercises great conservatism, not only because there are relatively large sums of money involved, but also because investors in this class of mining are unfamiliar as a rule with mining risks. The second is a class which, while speculative, are honest and legitimate undertakings. The development of mining prospects belongs to this category. Ventures of this kind should be confined to those who are willing and can afford to take greater risks in the hope of larger profits than accrue from the 'gilt-edge' mining investments. If the engineer has already established the reputation of being successful in his mining ventures, and has formed a clientele, for whom he has made money in these enterprises, he can afford to take some chance in risking the money of his clients in this more hazardous class of mining propositions. Here I wish to impress upon you the necessity of exercising great discrimination in choosing the capitalists to be associated with you in these respective enterprises. As your experience expands in these matters you will appreciate the importance of this injunction.

In making reports the young engineer should present copious technical data in case the report is to be submitted to other engineers, but when it is for the capitalist he should have in view chiefly the presentation of economic facts. Many of the reports of young engineers are altogether too voluminous to at-

tract the serious consideration of a busy capitalist. I have often been asked by young engineers what fees they should charge, and, while I have conscientiously advised fees 'as large as the traffic would bear', I have always suggested that it is sometimes more important to establish professional connections than to ask for remuneration which might result in the loss of such connections. Also, the young engineer should sometimes sacrifice the immediate monetary advantage, in order to get information which will be of subsequent importance to him. But I have at the same time been averse to recommending young engineers to make trips in order to see distant countries to the sacrifice of more substantial remuneration.

Your time as students has been fully taken up along technical lines. It has not been possible to embrace non-technical subjects in the curriculum of a mining school. But as you achieve distinction in your profession, you will come in contact with men prominent in other fields of activity, and you will feel the lack of a broad education, unless you acquire it by study after graduation. If you are well-read and have been a student in the liberal arts, your standing in the community, and therefore your importance in your profession, will be immeasurably increased. Finally, discharge your civic duties. You should, without the undue sacrifice of your professional opportunities, participate in the political movements affecting the localities in which you reside, and the welfare of the nation. For upon the welfare of our nation depends in a very large degree the prosperous conditions under which we can best succeed in our professional vocation.

THE MADILL OIL POOL, OKLAHOMA.

A report by J. A. Taff and W. J. Reed on the Madill oil pool has been published by the U. S. Geological Survey. Up to April 20 four producing wells had been drilled in a single quarter section 1½ miles southeast of Madill. The largest producer is estimated to have given 400 bbl. per day. The crude Madill oil is very liquid, with a gravity of 47.5° B., or approximately 7° higher than the best oil produced at Muskogee and 13° higher than the average Mid-Continent crude oil. The principal oil-bearing rock in this region, and the only one which has produced oil in quantity, is a deposit of compact sand and gravel a little more than 400 ft. below the surface at Madill. The oil sands have been reported to be 40 ft. thick, but it appears that the exact thickness of the pay-sand may not be over 25 or 30 feet.

The Prospector.

This department makes a charge of 25 cents to subscribers not in arrears and \$3 to non-subscribers for each determination. To ensure promptness in publication of the determinations, payment must be forwarded with specimens.

H. E. G., Montello, Nevada: Amphibolite-schist with quartz veins.

H. O. Y., Bowman, California: No. 1, a metamorphosed feldspathic rock, apparently an altered rhyolite or aplite; No. 2, quartzite. Both rocks are considerably stained by iron oxide.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Glass is used for lining the bottoms of launders at the Boston Consolidated mill, Garfield, Utah. It does not rust, as would metal, and resists abrasion better than wood.

Chat is used in the Missouri-Kansas zinc district to indicate the refuse from the concentrating mills, particularly the coarser particles. These generally consist largely of crushed chert, but in southeastern Missouri the same term is used, though the material is dolomite.

A metal surface, no matter how well polished, will always show under a strong microscope many irregularities. These irregularities, scraping one over another, and constant crumbling away, cause hot and cut bearings. Flake graphite fills up all these irregularities, building up the low spots, and forming over all a thin tough veneer of marvelous smoothness, and if for any reason the lubricant should fail, there is graphite-to-graphite contact instead of metal-to-metal, and the parts may be in contact for a long time without danger.

Monuments are deemed essential to validate a mining claim, except in the case of placer claims taken up according to legal subdivisions. They should be marked, and readily identifiable, otherwise it may prove difficult to hold ground against an adverse claimant who has complied with the regulations strictly. As a matter of security it is well not only to properly monument a claim, but to have witnesses, so that the fact may be capable of being fully substantiated in case, for any reason, the monuments should be destroyed.

Aggregates for fire-proof concrete giving the most fire-resisting property to the material, according to the recent progress-report of the Committee of the American Society of Civil Engineers on Concrete and Reinforced Concrete, are crushed igneous rocks. This is criticised by John S. Sewell, who affirms that such rock often spalls badly, and may be less desirable than limestone, and far inferior to crushed brick, terra-cotta, slag, and cinders. Mr. Sewell also insists on caution in subjecting concrete fire-proofing to any important structural stresses.

Assessment work for the benefit of a claim but not performed thereon is accepted by the courts, when the evidence is conclusive that such work is done in good faith for the purpose of subsequently mining the claim in question, and actually facilitates the extraction of mineral therefrom. Before venturing to expose a claim to adverse location by such work it is always well to take counsel of a competent attorney; or if any doubt exists as to whether such work might apply, follow the course of absolute safety and do the statutory work on each and every claim.

Bower-Barffing of cast-iron or steel is a process for developing a skin of Fe_3O_4 over the surface of the

metal, and of such depth as to prevent further oxidation. It is accomplished by heating the articles to a temperature of 1600°F . in closed retorts in the presence of superheated steam. A coating of Fe_3O_4 and Fe_2O_3 is thus formed. The Fe_2O_3 is then reduced to Fe_3O_4 by flooding the retort with producer-gas. The process had considerable vogue at one time, but, although extremely efficient, it is expensive, the cost ranging from \$5 to \$20 per ton on the cast-iron articles treated.

Paint coatings average only 0.003 in. thick, yet such a film is required to withstand expansion and contraction of the underlying surface, and abrasion or wear from without. It must penetrate and cling to the surfaces to which it is applied and must also retard or prevent free access to the underlying surface of both moisture and atmospheric gases, which cause decay. Very evidently, then, the physical and chemical character of the pigment particles themselves, the paint vehicle, and the lumber or metal to which the paint is to be applied must all be carefully considered.

Safe working-pressure for iron and steel-plate pipes may be calculated by the following formula:

$$P = \frac{1}{c} \left(\frac{T}{R} \right) \div f$$

Where P is the safe working-pressure in pounds per square inch, T the tensile strength of the plate, iron being taken at 48,000 and steel at 62,000 lb. per square inch, t the thickness of the plate in decimals of an inch, c the factor of safety, usually assumed at 4, f the proportional strength of plates after riveting, the factor being 0.7 for double-riveting and 0.5 for single, and R is the radius of the pipe in inches.

Crushing gold-ore in cyanide solution has been practiced on the Rand, and in many places in the United States and Mexico. The tendency under such conditions is to produce amalgam that is hard, 'dry', and brilliantly lustrous. It is desirable to feed mercury to the stamp-mill to keep the amalgam from becoming too hard; mere dressing of the plates is usually insufficient. The solution will also attack the copper of the plate unless the amalgam is kept well built up. Removal of the amalgam with steel scrapers is, therefore, particularly injurious. The amalgam must be softened and removed in the usual way. If necessary steaming may be resorted to.

Loss of head in friction is proportional to the length of the pipe, is increased by the roughness of the interior surface of the pipe, varies inversely as the diameter of the pipe, increases nearly as the square of the velocity, and is independent of the pressure of the water. This is all expressed in the formula

$$h = f \frac{lv^2}{2dg}$$

where h = loss of head in friction in feet, l = length of pipe in feet, d = diameter of pipe in feet, v = mean velocity in feet per second, f = a constant varying with velocity and diameter of pipe, g = acceleration due to gravity, and $\frac{v^2}{2g}$ = velocity-head due to mean velocity of flow. Tables for value of f can be found in many text-books.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

RIGHT OF PROMOTER TO GIVE STOCK IN SETTLEMENT OF CLAIM.

The promoters of a mining corporation had the authority to give a person stock in the corporation in settlement of a claim held by him against the mining property sought to be developed, and as a bonus for his services in raising funds. And such action was ratified by the other stockholders in receiving their stock where they had the option to receive their money or take stock in the company.

Canney v. McAllister (Utah) 101 Pac. 985, May, '09.

GAS AND OIL LEASE—CONSTRUCTION.

A gas and oil lease provided that if gas was found in any well, sufficient to justify saving and casing, the lessor should have a sufficient supply for domestic purposes and the lessee the remainder. It also provided that: "If, however, the second party shall use, market or sell gas from any well producing gas, it shall pay therefor fifty dollars per year for and during the time such gas shall be sold, marketed or used, except for drilling or domestic use of parties leasing to second parties. Under this lease the court held that the lessee was liable for the stipulated rental if gas was used by it for any purpose other than the drilling.

Mathes v. Shaw Oil Co. (Kan.), 101 Pac. 998, May, '09.

LEASE OF MINES—WHEN IRREVOCABLE.

A lease or license to operate a mine under the Wisconsin statute regulating mining, is irrevocable after a valuable discovery or prospect has been struck, but if the miner shall forfeit his rights by negligence such as establishes a forfeiture according to mining usages, then the lessor may revoke it notwithstanding a valuable discovery or a prospect has been struck. This rule permits revocation after discovery for a particular cause, but whether or not the cause exists is to be determined by proof of mining usages. However, the statute provides other causes for forfeiture after discovery, such as concealing or disposing of ores or minerals, or concealing or disposing of 'mines or diggings' for the purpose of defrauding the lessor of his rent, or neglect for three days after notice and claim of rent to pay rent on ores or minerals 'raised' by the lessee or licensee.

St. Anthony Min. & Milling Co. v. Shaffra (Wis.) 120 N. W. 238, March, '09.

LOCATION OF PLACER CLAIM—NOTICE.

A notice locating a placer claim, which was partly printed and partly written, read as follows: "Notice is hereby given that the undersigned in compliance with the requirements of the Revised Statutes of the United States have this day located the following described placer mining ground, viz: Commencing at the S. W. ¼ of the N. E. ¼ of Section twenty-three (23) T. 14 N., R. 10 E., situate in the Brushing Mining District, County of Placer, State of California. This claim shall be known as the Canothus Placer Mining Claim. Located on the seventh day of September, 1905. (Signed)." The words "commencing at" were in the printed

form, while the balance of the description was written, and while it did not appear that these two words were inadvertently left in the notice, still from the testimony of the locators, it was clear that they intended to locate the south west quarter of the north east quarter of the section described and that the words "commencing at" were expressionless and to be disregarded. Under the rule that location notices should be liberally construed, having reference to the circumstances under which and the character of the parties by whom they are generally given, and that the purpose of such notice is to identify the land claimed with reasonable certainty, the notice was held sufficient.

Green v. Gavin (Cal.) 101 Pac. 931, March, '09.

Japan's Mineral Output.

According to E. G. Babbitt, of the consular service at Yokohama, the total output of the mining industry in Japan during 1908 totaled \$51,583,000, a decrease of \$1,829,800 compared with the preceding year. The details are as follows:

| Mineral. | Value. |
|---------------------|--------------|
| Coal | \$30,981,700 |
| Copper | 11,201,900 |
| Petroleum | 3,237,700 |
| Silver | 2,132,800 |
| Gold | 2,073,000 |
| Iron | 963,500 |
| Sulphur | 383,400 |
| Miscellaneous | 609,000 |

COMPANY REPORTS.

ALASKA PERSEVERANCE MINE, JUNEAU, ALASKA.

STATEMENT OF OPERATIONS FOR MONTH OF AUGUST 1909.

| | Tons. | Gross value, estimated. |
|------------------------------------|---------|-------------------------|
| Ore broken in stopes, August 1.... | 197,572 | \$502,825 |
| Ore broken during August..... | 41,000 | 127,100 |
| Total | 238,678 | \$629,925 |
| Ore milled during August..... | 14,143 | 28,644 |
| Balance | 224,429 | \$600,281 |

There was recovered in bullion \$1.465 per ton or 72.25%, and in concentrate 35.3c. or 17.50%, giving a total recovery of \$1.82 or 89.75%. The loss in tailing was 21c. per ton or 10.25%. One hundred stamps ran 30 days of 8 hours each. Feed assays in mill averaged \$2 per ton. The costs, including mining 41,000 tons, 158 ft. of development, general charges, and tramming amounted to 42.6c. per ton. The milling cost, including repairs, haulage, freight, and bullion charges was 37.1c. per ton.

CONSOLIDATED MINING & SMELTING CO., OF CANADA, LTD.

A summary report of the production of this company is given below. The largest part of the ore treated at the smelter is mined by the company itself at Rossland, Phoenix, Moyle, and Sandow.

| Quarter ending June 30, 1908. | | | | Year ending June 30, 1908. | | | | Quarter ending June 30, 1909. | | | | Year ending June 30, 1909. | | | |

Publications Received.

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

ANNUAL REPORT OF THE SLUDGE ABATEMENT BOARD, 1907. Pp. 36. Melbourne, 1908.

MAP OF MADERA COUNTY, CALIFORNIA. State Mining Bureau, Ferry Building, San Francisco, 1909.

TUNGSTEN ORES OF CANADA. By T. L. Walker. Canada, Department of Mines, Mines Branch, No. 25, pp. 56. Ottawa, 1909.

COLLOID MATTER OF CLAY AND ITS MEASUREMENT. By H. E. Ashley. U. S. Geol. Survey, Bull. 388. Pp. 65, ill. Washington, 1909.

MAIN TUNGSTEN AREA OF BOULDER COUNTY, COLORADO. By R. D. George. Proc. Colorado Sci. Soc., Vol. IX, pp. 181-216. Denver, 1909.

THIRD ANNUAL REPORT OF THE BUREAU OF THE LOS ANGELES AQUEDUCT. Department of Public Works. Pp. 152, ill. Los Angeles, 1908.

An interesting report replete with valuable figures.

ELECTRIC SHAFT FURNACE, DOMNARFVET, SWEDEN. By Eugene Haanel. Canada, Department of Mines, Mines Branch, No. 32. Pp. 38. Ottawa, 1909.

An investigation of the operation of the furnace, with costs and figures.

GEOLOGICAL RECONNAISSANCE IN NORTHERN IDAHO AND NORTHWESTERN MONTANA. By F. C. Calkins, with NOTES ON THE ECONOMIC GEOLOGY, by D. F. MacDonald.

U. S. Geol. Survey, Bull. 384. Pp. 112, map, ill. Washington, 1909.

ORE DRESSING IN THE UNITED STATES AND MEXICO. By H. A. Guess. Proc. Colorado Sci. Soc., Vol. IX, pp. 235-258. Denver, 1909.

A general account with reports on numerous tests and with flow sheets of representative mills.

EXPLOSIVE MINE GASES AND DUSTS. By R. T. Chamberlin. U. S. Geol. Survey, Bull. 383. Pp. 65.

A thoroughly scientific study of a subject of large importance with notes having especial reference to explosions in the Monongah, Darr, and Naomi mines.

STRUCTURAL MATERIALS IN PARTS OF OREGON AND WASHINGTON. By N. H. Darton, U. S. Geol. Survey, Bull. 387. Pp. 33, map, ill. Washington, 1909.

This report includes a colored topographic map of Portland and vicinity and will be useful in all construction work.

IRON ORES, SALT, AND SANDSTONES. By G. P. Grimsley. West Virginia Geol. Survey, Vol. IV, pp. 603, ill. Morgantown, West Virginia, 1909.

The investigation shows the presence of large surface exposures of iron ore suitable for use in making open-hearth steel.

REPORT OF THE SLUDGE ABATEMENT BOARD FOR 1908. Pp. 31. Melbourne, Victoria, 1909.

This report contains accounts of hearings regarding stream pollution by mining debris with numerous determinations of the amount of matter carried in suspension by the streams.

STATE GEOLOGICAL SURVEY OF NORTH DAKOTA. FIFTH BIENNIAL REPORT. By A. G. Leonard. Pp. 278, ill., maps. Bismarck, 1908.

This excellent report includes an account of the coal resources, the cement materials, the road materials, the gas fields, and the general geology of the State.

MINERAL CONTENT OF ILLINOIS WATERS. By Edward Bar-

tow and others. State Geological Survey (Illinois), Bull. 10. Pp. 192. Urbana, 1909.

A general classification and study accompanied by numerous analyses and with notes on the geological distribution, industrial uses, and therapeutic properties of the waters. A handy book of useful information.

L. C. PRINTED CARDS, HOW TO ORDER AND USE THEM. By C. H. Hastings. Pp. 24. Washington, 1909.

The Library of Congress issues index cards covering the publications of the United States and the State Geological Surveys as issued. This pamphlet gives details and quotes costs. It may be obtained upon application to the Library of Congress, Card Section.

MINERAL RESOURCES OF THE UNITED STATES, 1908. U. S. Geol. Survey, Washington, 1909.

Advance chapters as follows have been recently received: Abrasive Materials, by W. C. Phalen; Asphalt and Related Bitumens, by J. A. Taff; Peat, by C. A. Davis; Coal Briquetting, Coal, Coke, and Coke By-products, by E. W. Parker; Graphite, by E. S. Bastin; Mica, by D. B. Sterrett; Mineral Paints, by E. F. Burchard; Mineral Waters, by Samuel Sanford; Petroleum, by D. T. Day; Precious Stones, by D. B. Sterrett; Salt and Bromine, by W. C. Phalen; Tin, by F. L. Hess.

GEOLOGICAL MAP OF OHIO. By J. A. Bownocker. Scale 8 miles to the inch. State Geologist, Columbus, Ohio. Price, 25 cents.

The last previous geological map by the State Geological Survey was published in 1888. The new map shows much additional detail regarding the formations, and a large amount of information of economic character. Among other features are the oil and gas-producing areas, the railroad and river-shipping coal mines, portland cement plants, salt works, and the gypsum deposits. The publication of such maps is among the most useful functions of geological surveys.

STRUCTURAL DETAILS, OR ELEMENTS OF DESIGN IN HEAVY FRAMING. By Henry S. Jacoby. 8vo., pp. 377, ill. and plates. Index. John Wiley & Sons, New York, 1909. Price \$2.25.

This volume represents the course given by the author upon this subject in Cornell University. It is a systematic treatise on practical design and execution of work in timber-framing for large structures. A knowledge of the principles of mechanics is assumed throughout. Great stress is laid upon the design of joints, beams, and trusses, many details being given, and illustrations in profusion elucidate the text. It is a work which will be an aid to every mill constructor where steel framing is not possible.

GOLD REFINING. By Donald Clark. 8vo., pp. 125, ill., index. Melbourne, Australia, Australian Mining Standard; London, Isaac Pitman & Sons, Ltd.; 1909. Price \$4.

This is a small book, but full of meat. Donald Clark writes from fullness of information, knows what he wants to say, and says it simply and in few words. The brevity of many of his references to points in technical method is extreme—only a line or two—but on examination it turns out that he has stated all that is worth while, and quite enough for any trained man to successfully carry out the operation indicated. As a single example, he says of purifying gold bullion, "one method consists in retorting with iron-filings, the object of the iron-filings being to remove the sulphur. This cannot be done at the temperature attained in retorting." A general review of refining with oxidizing and chloridizing agents is given; a chapter is devoted to sulphur refining, another to cementation processes, and one to refining with oxygen or air. Miller's process of refining with chlorine gas, practised with great success at the Sydney mint, is given in detail, aided by illustrations. The range of the treatise will appear from the further topics, parting with nitric acid, recovery of silver from nitrate solutions, refining by means of sulphuric acid, parting gold by electrolysis, electrolytic refining of gold, treatment of cyanide precipitate, nitre-cake method of purifying slime, and the refining of base bullion. It is an admirable little work, full of information and suggestiveness.

BENGUET, in the Philippines, is becoming an im-
portant producer. The Benguet Consolidated
is now yielding, approximately, \$6000 per month. In
the Paracale district the French seem likely to fol-
low New Zealanders and Americans in investing. At
Manila they are talking ambitiously of a million dol-
lar gold output for the year. The mining industry
of the Islands seems to be in a healthy condition.

THE SECOND number of *The Mining Magazine*
sustains the high standard set by the first. Mr.
T. A. Rickard writes in his usual lucid manner of
Hydraulic Mining in Alaska, Mr. W. E. Hindry gives
a pen-picture of the Esperanza mine, Mr. C. H. Jones
contributes a frank account of difficult work in
copper smelting in the Argentine, and 'an Occasional
Contributor' writes of Mining Accidents in Cornwall.
The reviews, company reports, and précis of technol-
ogy, illustrate excellently the good work which falls
within the peculiar field of a magazine, as does also
the mining review of the month.

WE TAKE PLEASURE in announcing that Mr.
C. F. Tolman, Jr., has joined our staff of
Special Contributors. Mr. Tolman has special knowl-
edge of the copper camps of Arizona, and we publish
a third of his illuminating descriptions in this issue.
In future contributions he will discuss the Miami-
Inspiration and Silverbell districts. A graduate of
the University of Chicago, with experience in chem-
ical work at Butte, in mine management in Mexico,
and in teaching at the Arizona School of Mines, Mr.
Tolman brings to all that he writes a penetrating
insight. He has already received a hearty welcome
from our readers.

CONSTERNATION has been brought to the oil
prospectors in Mexico by a clause in the tariff
bill now under consideration by the Chamber of
Deputies. The proposal is to admit the importation,
without payment of duty, of raw materials destined
to be manufactured, adapted, or modified within the
Republic for the purpose of exportation in whole or
in part. No specific mention is made of oil, but the
measure is gratifying to the Pearsons, who are
equipped for refining, and it is pointed out that the
importation of crude oil from the United States, and
the exportation of a part of the refined products to
Europe, selling the remainder in Mexico, would be
a profitable business. It would, however, discourage
prospecting, and prove a crushing blow to the smaller
producers. The excuse offered for this proposed
law is the inadequacy of the developed oil-supply for
domestic Mexican needs, but the amount of explora-
tion in comparison with the area where oil may be
expected is too insignificant to justify legislation at

this time that must impede further investigation on a scale which would prove or disprove the possibility of Mexico producing her own supply. If the facts are as represented the good sense of the Mexican Government will forestall such crippling of a rising industry which has proved attractive to foreign capital. That country has more to gain for a long time to come from developing her own resources than from merely manufacturing the raw materials of others.

IT IS ANNOUNCED that the gold medal donated by the Consolidated Gold Fields of South Africa and awarded annually by the Institution of Mining and Metallurgy, has been given to Mr. W. A. Caldecott "in recognition of his work in the investigation of methods of reduction and treatment of gold ores, and of his contributions to the literature of the subject." Mr. Caldecott merits the high distinction. He works in the true scientific spirit, and the advances in metallurgy made under his direction constitute forward steps in practice. His examination of Mexican methods of cyaniding silver ores attracted wide attention in this county and had an important influence in stimulating further research by our own metallurgists.

COMMENDATION is due General Bernardo Reyes for his patriotic self-effacement in not only withdrawing from the vice-presidential race in Mexico, but in temporarily retiring from the country. No other course could have been trusted to extinguish intemperate zeal on the part of the Reyista faction. While revolution was not to be apprehended, hot-headed political demonstrations would have given color to alarming reports had General Reyes remained at home. Such reports would have lowered the National credit and have impaired the growth of industry. The opponent of the administration gracefully accepts employment under the Government as special commissioner to study European military methods, and will remain abroad until after the elections.

FORESTRY and mining should go hand in hand, despite minor points of inevitable conflict. Actually, so far, the Forest Service and the miners have been in almost constant disagreement. The American Mining Congress, some time since, appointed a committee to confer with Mr. Gifford Pinchot, the Forester. A number of conferences were held and many points of disagreement were eliminated. It is understood that the remaining difficulties, relating in part to the use of timber taken from one unpatented claim to develop another, are to be discussed at future meetings between representatives of the Service and a new committee authorized at the Goldfield meeting. In the meantime we present in this issue the substance of an address made at Goldfield by Mr. W. W. Dyar, representing the Forest Service. Its fairness and breadth of view will be at once recognized by all who have watched with growing concern the friction generated by the past administration of the National Forests. For the benefit of those to whom Mr. Dyar is a stranger, we may say that he was trained as a lawyer, but got

an intimate knowledge of mining conditions later while managing dredges and hydraulic plants in Summit county, Colorado. He has learned by experience what are the difficulties of mining, even to the point of having himself been in conflict with the Forest Service. His appointment as law officer in the Service, and his detail to consider the especial questions that arise in connection with mining problems in the Forests, are the best possible evidences of the desire of the Forest Service to right as far as may be the real wrongs of the protesting miners.

The Copper Situation.

A prominent producer of copper the other day characterized the situation as 'delicate'. Prices are decreasing while prosperity is supposedly in the ascendant. This proves some peculiarity in the metal market that the public imperfectly comprehends. Spelter has risen sharply as a result of tariff changes and in response to demands for galvanizing sheet-iron; steel continues below the average prices in 1907, and copper is at low ebb, with stocks steadily accumulating. It is affirmed that the consumption increased in October, but this was due to the inducement of special prices made to secure large orders. Electrolytic copper has recently sold as low as 12½ cents. The available world-stocks are estimated at 400,000,000 pounds, which is more than one-fifth of the total annual production. As a result buyers are in the market only to supply current needs, the manifest expectation being that prices will recede. This must be disappointing to the cheerful prophets of 15-cent copper by January 1. Since the average cost of producing copper throughout the world is at present nearly 11 cents, curtailment of output is imperative. In this necessity lies an obstacle to forming an association of copper producers; it would chiefly benefit those who are writhing under the pinch.

The bankers are growing fearful of carrying the burden of excessive stocks of copper, and the contango, which is the price paid for deferring fortnightly settlements in the London market, has mounted to 22 shillings 6 pence per long ton. This will quickly involve the copper producers in unsupportable difficulties. The hard terms exacted have been partly occasioned by the advance of the Bank of England discount rate to 5 per cent, a penalty imposed upon the reckless stock speculation in Wall Street during the last two or three months. Trading in copper warrants has long been a favorite form of speculation in London, and efforts have been made recently in this country, particularly in Boston, to secure the co-operation of the public in helping to carry the load of overproduction in the same manner. We believe the response to this invitation has not been cordial. The burden of the copper miners cannot be shifted easily to other shoulders, and no relief can be obtained by mere restriction of the output at individual mines. The attempt to do that only increases the cost per pound of the lessened quantity. On the other hand, closing of mines means enormous losses from injury to underground workings and from deterioration of plant, or else continuing costs for pumping and preservation of equip-

ment. The anxiety of the operators to avert actual suspension of work is thus seen to proceed from motives of economy, and in many cases it will prove a better business policy to continue production at some actual loss.

As opposed to this stands the fact upon which we have commented optimistically from time to time, that those who presumably should know the present situation best, and should be best able to forecast the future, have been acquiring new properties, and expending millions in providing equipment for increased production on an enormous scale. The construction of the smelter in Pine canyon, Toole county, Utah, by the International Smelting & Refining Company, the equipment of the Miami and Ray properties in Arizona, to mention only a few, can safely be accepted by the public as evidence of faith in things unseen—at least in things beyond the clouded vision of the man in the street. Messrs. T. F. Cole and J. D. Ryan must have confidence in high prices at no far off period, sufficient to reimburse them for courageous investments which at present offer no visible profit.

Until the consumption of steel increases markedly no important improvement in the copper market can be anticipated. The earnings of the Steel Corporation have notably augmented on a tonnage inferior to that of two years ago. This result has been obtained through reduction of costs by means of the facilities afforded at the new Gary plant. Advantage was taken of these improvements to reduce the price of steel, which has had a beneficial effect on business in general, though its influence seems not to have stimulated new enterprises which would react favorably upon the demand for copper. Conditions at the moment are unpropitious for a decided revival. The impression prevails that the copper producers are in stress of circumstances. That means that consumers are counting upon a further break in prices. While that opinion prevails orders for future delivery will not materialize, and these constitute the basis for real vitality in any industry.

Mr. Heney's Defeat.

Reform has received a backset in San Francisco. At the election November 2, Mr. Francis J. Heney, candidate for the office of District Attorney, on the platform 'Equality before the law', went down to defeat before Mr. C. M. Fickert, running on the platform 'Let us have peace'. At the same election Mr. P. H. McCarthy, Union Labor candidate, a partisan and defender of Schmitz and Ruef, was elected mayor on a platform demanding a wide open town. It will be hard for friends of San Francisco at a distance to understand how this was brought about without any suspicion of the fairness and honesty of the election. Ever since the graft exposures began in this city Mr. Heney has been at the storm centre. He found here a nasty situation and he has fought valiently and steadily to better it. He fought the Devil with fire. Whether it would have been possible to accomplish anything by using cologne instead may well be doubted, but the fact remains that such fighting here, as always, produced resentment, engendered bitterness, and led to defections from the ranks of

those who ought to have stood solidly behind efforts at reform. More than that, to the large element which measures only by results, nothing direct seemed to have been accomplished. None of the grafters has been sent to prison. While it is true that indirectly much good has been achieved, the people as a whole evidently do not see this, and the charge of ineffectiveness has been lodged against the graft prosecution. This failure is generally ascribed to Mr. Heney's methods without much regard to whether or not any other methods were possible or would have brought larger results. It was this, we believe, which operated to defeat Mr. Heney personally. It was inevitable. The public repeatedly uses a man, accepts his results, blames him for failure, and casts him aside. Mr. Heney has too much experience and good sense to do other than accept the situation philosophically. He can no longer fight officially, but we are glad to see he has already enlisted in the ranks. Americans love a good fighter—and a good loser, and by these and many other tokens, Americans love Mr. Heney and wish him well.

Entirely aside from the personal opposition to Mr. Heney, there were general and underlying causes which insured the defeat of the candidates of the Good Government League. It is well to remember that American cities, despite family quarrels, are insistent on presenting a united front to outsiders. Local strife which affects the material prosperity of the city becomes unpopular, no matter how worthy the cause. This made effective the appeal of Mr. Fickert for a 'get together spirit.' The city was tired of strife and deliberately decided it were better to drop the graft prosecutions than to keep them up at that cost. We can only hope that the future may have in store some such delightful surprise as came to Chicago when Mr. Wayman was elected State's Attorney to stop attempts to enforce the Sunday-closing law. He stopped them, it is true, but has created consternation among jury-fixers, has sent a prominent police inspector to the penitentiary for black-mailing prostitutes, has forced the resignation of a complaisant Chief of Police, and has cleaned up the worst features of the red-light districts. Mr. Fickert would do well to study Mr. Wayman's career and growing popularity. There is plenty to do in San Francisco, even if the graft prosecutions be stopped.

As for the new mayor and the business men who either directly or indirectly made sure of his election, we can only re-affirm our opinion that even on the narrow basis of business it is a vast mistake for a city to elect a chief magistrate pledged to a wide open town, 'reasonable construction' of 'stringent and unreasonable ordinances' with the emphasis on the 'pleasure-loving' character of the people. San Francisco must sell bonds to carry out the public improvements under way, and with the memory of Schmitz and Ruef fresh in mind, we anticipate that the bond market will be tight.

General reform is bound to go ahead. We refuse to be discouraged. The advance or retreat of a single wave does not measure the direction or force of the tide, and we believe as firmly as ever that the tide sets deep and strong toward better government.

BY THE WAY.

At the inauguration of the Graduate School of the State University of Illinois, Mr. David Kinley discussed the subject of 'Democracy and Scholarship'. We abstract this address below:

The most noteworthy fact in nineteenth century history is the onward sweep of democracy. It has shown itself not only in the formal establishment of republican forms of government, but in the virtual establishment of the power of the people in countries where aristocratic and monarchic forms of government have been maintained.

Democracy has not won its way, however, without arousing a good deal of criticism. There are prophets, not a few, crying in the wilderness of exploded political and social conditions that the success of democracy means the decay of refinement, the destruction of the higher ethical, intellectual, and spiritual motives and ambitions; and the substitution of the gray gloom of mediocrity, in all departments of life, for the brilliant, if sometimes flaunting, diversity and exuberance of talent and activity that are fostered in the supposedly more genial atmosphere of an aristocracy. Nor are these critics of democracy so unimportant as to deserve scant attention. It is asserted with much show of logic and much parade of evidence that democracy and scholarship are irreconcilable. It is hardly worth while to criticise the somewhat preposterous statement that aristocracy favors culture more than democracy. For, in the first place, aristocracy as a form of government and of society has had a far longer lease of life in the world's history than has democracy, so that a fair comparison can not be made. Moreover, we certainly can not say that the members of any aristocracy have been the developers of culture, or its exponents. It is probably true that more of them have been devoted to the racing track than to poetry and art, and to the exploitation of the rest of society by war and government than to the promotion of their interests by letters and the arts. The long list of names great in science, art, poetry, literature, and philosophy is composed largely if not mainly of those of poor men of the middle or lower class. The only sense in which it can be claimed that an aristocracy is favorable to culture is that its members act as patrons of culture and have aided its devotees.

Later prophets warn us that democratic materialism, commercialism, and the demand for the practical are killing pure science and throttling literature. But yesterday a Cassandra voice in our midst announced that there is no scholarship in this democratic country of ours. When these critics are told to look about them and see what this democratic people of ours is doing to promote higher education and to stimulate scholarship and research by their great public school system and their State universities, unable to deny the facts, they take refuge in a subterfuge. They tell us as did an Eastern university president, that while it is true that many of the States are promoting higher education, it is a kind of higher education which is not consonant with, but antagonistic to, culture. We are told that the State universities may develop practical education, that

from them we may look for great results in engineering and in agriculture, and in all those matters which are sometimes criticised as 'bread and butter' studies; but for things of the spirit, we must look to those institutions which depend for their existence on private beneficence; that only here, free from the agitation and the tyranny of a democratic majority, can we hope that the pure light of learning will be kept burning. This criticism involves two assumptions, the mere statement of either one of which makes the whole position ridiculous. If the criticism be true, then it must be that the choice spirits are to be found at endowed universities only, or else it must be that the people, the democratic majority, refuse to have culture in their State institutions, an assumption which by no means is justified by historical facts or *a priori* theory.

In spite of all these criticisms, however, democracy is reaching out and taking possession of the field of higher education. I venture to put forward and to defend the thesis, not only that democracy is not incompatible with high scholarship in any line, but that, on the contrary, the cultivation of scholarship by democracy is necessary to its stability, progress, and perpetuation. I assert that, using scholarship in a broad sense, the permanent interests of developed democracy demand that the pursuit of knowledge shall be made in its own interest, by its own servants, supported by itself, to the end that knowledge shall become the general property of the community.

There is truth in the charge that scholarship has not developed in the United States, which may be regarded as a representative modern democracy. It is true that we are suffering now-a-days from an excess of materialism, from the arrogant assertions of positivistic science over imagination and spirituality; from the subjugation of idealism to realism, and from the too great importance attached to mere material prosperity. But it is not alone the greatest democracy of the world that is thus suffering, although perhaps it suffers more than others. The condition exists throughout the civilized world, and we hear protests against materialism from the apostles of the ideal in every country. It is a passing phase of civilization. Civilization does not move forward equally in all directions at the same time. It develops first on this line, then in that direction, and later on still another plane. The great geographical and industrial discoveries of the past century have put emphasis upon material growth for the present, and the light of things spiritual seems low by contrast. But that light has not gone out. Mankind has seen similar conditions before, and now, as hitherto, they are but temporary. In the United States, particularly, men have been obliged by the conditions attached to life in a new country to devote themselves to the pursuit of economic success. A nation, like an individual, can do only one great thing at a time. Our work during the first century of our existence was that of the conquest of a continent. In the second place, democracy has not until lately joined itself with the educated classes for the promotion of scholarship, because it has distrusted scholars and scholarship for the reason that in the past they have been the allies of aristocracy.

NATOMAS 1500-TON PLANT FOR CRUSHING DREDGE-TAILING.

Written for the MINING AND SCIENTIFIC PRESS
By GEORGE BOWERS.

The rock-crushing plant recently installed at Fair-oaks, California, by the Western Engineering & Construction Co. of San Francisco for the Natomas Consolidated makes possible the utilization of the rock-tailing piles from the company's gold dredges. These rock piles rise 20 to 45 ft. above the original ground level and cover many hundreds of acres along the American river and also along the Feather river near Oroville. This land had never been valuable for cultivation, only 10% being so used; and, although the gold dredges left it entirely barren, it was no great loss.

By the present system, however, all the mineral resources of the land are utilized. The great piles of rock tailing are put through the crushers and sold for road-metal, railroad ballast, concrete, etc., and

portance of a co-product. The rock is of good quality and is pronounced by experts to be the finest road-ballast obtainable in California.

The introduction of many novel features in the arrangement of the rock-crushing plant, which was designed as well as erected by the Western Engineering & Construction Co., has rendered its operation so simple and direct as to be almost automatic.

Bucyrus Steam-Shovel Loading Tailing.

Storage Piles for Crushed Tailing.

the land once 90% barren and useless is transformed into valuable orchards, vineyards, and eucalyptus groves, capable of supporting a large population. The Natomas Consolidated, which is the largest gold dredging and reclamation company in California, quickly realized the advantage to be gained by clearing away these piles of tailing and putting all the dredging ground under cultivation. Last year the company planted 1600 trees on this ground, and they are all in a healthy condition today, not one having died. They are shown in one of the illustrations.

The economic advantages of the new industry developed here have proved more numerous and more important than was at first expected. The unsightly useless gravel area is being converted into tillable soil; the region is being re-forested, and occupation has been furnished to a number of laborers and mechanics. Beside all these, the returns from the sale of the rock has proved so profitable that this industry has been lifted from a by-product of the gold dredging to almost the im-

The Natomas Consolidated owns and operates three rock-crushing plants, having a total output of 115,000 tons per month.

The rock-crushing plant known as No. 2 has a capacity of 1500 tons per day of 10 hours. The general arrangement of the plant is shown in the figures. The rock in the tailing piles to be crushed is excavated by means of a 40-ton Bucyrus, oil-burning, steam-shovel, mounted on 60-lb. rail, standard-gauge, portable track, parallel with the rock-pile. The rock from the shovel is deposited in a train of Koppel cars, each of 4 cu. yd. capacity, mounted on 40-lb. rail, narrow-gauge, portable track, in a

Crusher Plant for Dredge-Tailing.

loop to enable the loaded and empty cars to pass each other without the necessity of switching while returning to the shovel for a new load. The cars are hauled to and from the shovel by means of a 10 by 14-in. dinky engine, burning oil as fuel.

This loop and its relations to the receiving hopper are shown on the accompanying flow-sheet. The

Section Through Natomas Crushing Plant for Dredge-Tailing.

plete plant is ready for operation again. There are seven separate storage piles of crushed rock, each 100 ft. long by 40 wide and 40 high. The size and class of material is as follows, 3/8-in. to dust, 3/4, 1 1/2, and 2 1/2-in. rock, all which is an A1 product from the jaw-crushers. The material from the rolls is a second-class product in sizes of 3/4 and 1 1/2-in. rock. The seventh rock pile is composed of 3/8-in. round pebbles screened direct from the tailing pile, without being crushed, and is used as roofing pebble.

In the centre of each of the seven storage piles, below the ground-line, is a re-inforced concrete tunnel, 110 ft. long, 6 ft. wide, and 6 ft. high, inside dimensions, having the roof and sides and bottom 12 in. thick. Each tunnel is provided with a 24-in. Robins conveyor, 185-ft. centres, running at a speed of 250 ft. per minute, the conveyor raising from the ground at an angle of 18° to a height of 25 ft., and then running parallel to the ground over the railroad tracks for a distance of 25 ft., discharging into a swinging chute, so placed as to direct the rock alternately into the railroad cars on two distinct tracks. Each tunnel is provided with four gates, spaced 20 ft. apart. The gates are of the swinging-door pattern, and all gates are connected by means of levers and rods, and can be operated separately or together from one hand-wheel at the mouth of the tunnel. The third track is loaded direct from the crushers by means of an inclined chute from the head of the conveyors, from No. 10 to 16 inclusive; also an auxiliary chute is installed in the aforesaid chute at the lower end to divert the material when necessary to discharge to the No. 18 conveyors and thereby load the cars on the first and second tracks. With the above arrangement it is possible to load cars on two separate tracks from the storage-piles, and also it is possible to load cars on three separate tracks direct from the crushers, without the rock going into storage. The total equipment for the rock crushing plant consists of: 1 screen A, 72 in. diam. by 22 ft. long; 2 screens E, F, 60 in. diam. by 24 ft.; 3 screens B, C, D, 48 in. by 10 to 12 ft.; 1 Bacon, 24 by 26 in. jaw-crusher; 3 Bacon 36 by 10 in. jaw-crushers; 2 Allis-Chalmers 40 by 20 in. corrugated rolls; 1 Allis-Chalmers 40 by 15 in.

smooth roll; 30 Robins Conveying Belt Co.'s conveyors having a total length of 4152 ft.; four electric motors, 50 hp.; one 75 hp.; five 100 hp., and two 150 horse-power.

A main motor-house, 24 ft. wide by 60 ft. long, with timber framing, and covered on the outside with No. 24 corrugated iron, is erected to house the main motor and equipment. The pilot house, 24 ft. square, is mounted on the roof of this motor-house, giving the operator a clear view of the entire plant. All electric motors for the plant are controlled from this pilot house.

The switch-board and controllers are a new and novel combination, designed especially to meet the requirements of this plant. A separate and different colored light is installed directly over each controlling switch, and a duplicate light and auxiliary switch is placed close to each electric motor controlled from the pilot-house. Each motor has a push-button and an electric bell near the auxiliary controlling switch. Each motor is designated by a certain number of rings on the bell. In case any part of the plant gets out of order, the man in charge of that particular part of the plant signals to the operator

Character of Ground Before Dredging. Dredge-Tailing in Distance.

in the pilot-house, who immediately closes down all or any part of the machinery affected by the breakdown, and at the same time telephones to the foreman of the repair-gang, who is in the repair house, telling him exactly where to go to find the trouble, thereby avoiding waste of time. All the electric wires to the different motors from the pilot-house are laid in underground conduits, therefore there are no exposed wires around the crusher-plant to endanger the lives of the operators. Electric power is delivered to the crusher plant at 60,000 volts, and is transformed down to 2300 volts, and distributed to all motors at 2300 volts. The transformers are in a concrete tank, installed below the ground-line, and completely covered. The transformers below the ground-line and the concrete tank being provided with drains to carry any waste oil away to the river, lessens the possibility of fires from this source.

A hand-operated overhead crane, having a lifting capacity of 10 tons, a span of 40 ft., and 30 ft. clear head-room, is installed upon a timber-structure 100 ft. long, placed over the crusher machinery, and extending up to the repair-house, where all supply and extra parts are stored. The repair-house is 24 ft.

wide by 48 ft. long, and is equipped with a complete set of tools and machinery to carry out necessary repairs to the plant.

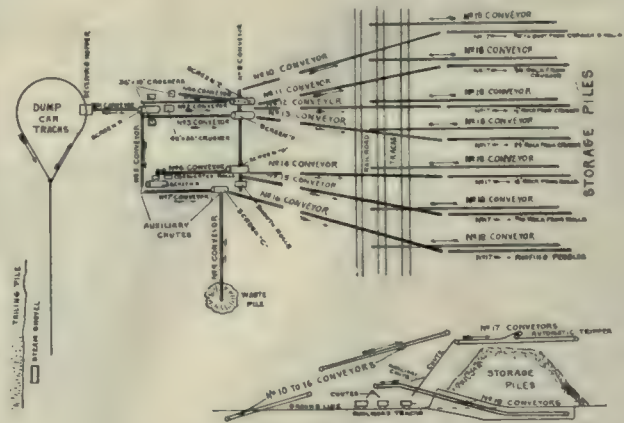

Two steel tanks, 11 ft. 6 in. diam. by 10 ft. deep, are mounted on a timber super-structure 20 ft. above the ground, and are placed midway between the railroad tracks and the steam-shovel site. The oil-pump is near the railroad track, and delivers the oil from the railroad cars into the storage-tanks. The pipe-

Dredged Ground After Leveling Tailing and Planting Eucalyptus.

line from the storage-tanks is laid underground and is provided with ground-cocks spaced every 80 ft. up to the shovel-site, to supply fuel-oil to the dinky-engine and steam-shovel.

Two steel-tanks, each 11 ft. 6 in. diam. by 10 ft. deep, are mounted on a timber super-structure 30 ft. above the ground, and near the crusher-site, to supply water to the shovel and railroad engines, and also for fire purposes to the entire plant. The water is delivered to the tanks by one 8-in. centrifugal pump direct-connected to a 50-hp. motor. A most complete pipe-line for fire purposes has been installed, amply supplied with hydrants and fire-hose, placed in convenient positions around the crusher-plant. A Fairbanks iron-framed railroad track-scale,

Flow-Sheet of Crushing Plant.

with 50-ft. platform, and a capacity of 200,000 lb., is installed in a convenient position along the spur-track leading to and from the storage-piles, to weigh the cars of crushed rock being shipped.

The plant is operated with the following labor: superintendent, steam-shovel engineer, steam-shovel engineer helper, locomotive engineer, gravel train brakeman, two laborers moving tracks of shovel ahead, two laborers unloading cars at dump or receiving hopper, one laborer regulating the receiving-

hopper door feeding the rock to No. 1 conveyor, four laborers attending the four crushers and two rolls, three laborers attending to loading of cars at storage-piles, two laborers placing side-boards on railroad cars, two laborers oiling conveyors and countershafts, one main operator in the pilot-house, one electrician for motors, one mechanic in repair-house.

The steam-shovel takes 8 minutes to load a train of 7 cars of 4-cu. yd. capacity. The dinky-engine hauls the train of cars to the dump-hopper, and returns the empties to the shovel in 7 minutes. It takes 10 minutes to load a 40-ton railroad car at the storage-piles, and two cars can be filled at the same time with the same size of rock. There are 7 separate piles of different sizes of rock. Therefore, it is possible to load 12 cars per hour, making a shipping capacity of each size of rock of 480 tons per hour, to fill a rush order for rock providing the cars are at hand.

The crushed rock is unsurpassed for concrete, asphalt macadam, and macadam roads. It also binds perfectly with crude asphaltic oil. The crushed rock weighs as follows: $2\frac{1}{2}$ in. size, 2592 lb. per cu. yd.; $1\frac{1}{2}$ in., 2580; $\frac{3}{4}$ in., 2330, and from $\frac{3}{8}$ in. to dust, 2400.

A test upon the quality of this rock, made by Smith, Emery & Co., of San Francisco, credits the material as being mainly basalt, specific gravity, 2.94, hardness 5, absorption 0.01, and voids 50 per cent.

In the rattler-test a charge of 100 lb. dry rock, at a speed of 28 rev. per min., in 5040 revolutions was reduced to 90 lb., showing loss by abrasion of 10%. Of the dust from the 'rattler', the amount retained on 4-mesh was 2%, on 10-mesh 0.5, and fine 7.5 per cent.

The commercial value of monazite depends upon the incandescent properties of the rare earth oxides which it contains, such as cerium, lanthanum, didymium, and thorium oxides, which are used in the manufacture of the Welsbach and other incandescent gas-light mantles. It is the thoria that is used in largest amount and which gives the actual value to the monazite. In the reduction of the monazite sand there are a number of rare earth salts that are obtained in considerable quantity, which has made it possible to carry on an extensive series of experiments with these rare earth oxides. It requires from four to six months to recover from the monazite sand its content of thoria and render it sufficiently pure to be used in the mantles.

Sludge is soft water-soaked mud or mire. The term is applied to muddy or pasty refuse of various kinds, such as escapes from coal washeries. In metal mining it refers to the mixture of fine rock powder and water resulting from the action of a drill in boring. It is also used to denote the tailing escaping from buddles, vanners, and other concentrating machines for handling fine material. For this, slime is also used, but in modern practice the latter term has come to mean a finely ground ore worthy of further treatment, and does not generally signify a waste product, as does sludge. In petroleum refining sludge is used to designate the refuse acid and alkali solutions coming from the agitators.

DRILLING FOR OIL IN EASTERN ILLINOIS.

Written for the MINING AND SCIENTIFIC PRESS
By R. S. BLATCHLEY.

The successful and phenomenal growth of the Illinois fields within the last four years may be attributed in large part to the careful study of conditions on the part of the operators. The rapidity of the extension of the field is remarkable when it is noted that 95% of the bores within the field were successful and only 5% were dry. As drilling advanced southward from Casey and Westfield into deeper fields around Robinson and still deeper territory around Bridgeport, new tactics had to be used. The advance was not indiscriminate, but was cautious though continuous. Limits were determined by the bringing in of a dry hole that either failed to show the sands or yielded salt water. Such a hole meant a shifting of development inward. The early drilling indicated a southward trend to the field and the movement of drills continued in that direction. As the field stands today, with its few failures as compared to the general success, one cannot help but feel that Illinois has added its share to the fund of knowledge of oil development as well as to production.

There are many different steps necessary to the successful development of oil properties, and the novice will find himself confronted continually by perplexing problems. He often fails, while the experienced man is able to meet conditions. The first step is to locate properties as near as possible to producing wells. The old operator watches the growth of the field from the first news of striking oil and makes his locations, provided he has the necessary leases, only when he feels that they are within the limits of known productive territory. The uninited more often is attracted to outside territory and his bore is strictly a 'wild-cat' proposition. Any observer of the oil business will soon note that the larger companies and operators do but little wild-cattling and profit by the experience of these small operators. It is true, however, that field limits are only established by these test bores.

There is no set rule concerning leasing, as it necessarily is dependent upon conditions. In most cases properties are leased, usually for a period of five years with options of further lease, and as much longer as production continues. If when leasing, the adjoining territory is untested, the farmer usually receives from one-eighth to one-sixth royalty on the future production, with the further stipulation that drilling is to begin within one or two years, or that a stated rental per acre be paid until the first well is drilled. In case the land-owner has property near proved territory, it naturally takes on added value and a bonus is demanded. The closer he is to good oil properties, the higher the bonus that is demanded, often reaching as high as \$200 to \$300 per acre. The average bonus in Illinois on land adjoining good oil properties, ranges from \$30 to \$100. The land-owner retains all rights over the surface of the land with the exception of the portion necessarily used by the oil operator for his wells, power-house, boiler-house, tankage, and waste-pit. Upon an 80-acre tract not more than six acres are necessary for

this, even though a full quota of wells be put down. In an industrious community the farmer tills his land at the same time that he derives income from oil. Stipulations are generally made regarding the use of gas by the land-owner and of payment per year from the sale of gas from gas wells. This generally averages from \$100 to \$125 per well. Also it is usually agreed not to drill wells closer than 200 ft. to any dwelling or barn, except in the cases of town lots. It is further agreed that the lessee shall be responsible for all damages caused to growing crops and usually that all pipe-lines must be buried below plow depth. If, on the area leased, some good wells are developed, the lease, like the franchise of a street railway, becomes the most valuable part of the prop-

the lease under consideration were 40 acres and had 8 line wells, each producing approximately 10 bbl. per day from the same sand, the total estimated production for that lease would be 96,000 bbl. At the value of 60c. per barrel, the lease is worth \$57,000, or in the terms of a bargain \$50,000. If the estimates were carried further, a 10-bbl. well in a 15-ft. sand would roughly yield 3000 bbl. during its life. These estimates are considered further in relation to the depth of the sand and to the daily production, that of 15, 20, 25, 30-bbl. wells producing in 5, 10, 15, 20, 25, 30, 35-ft. sands. The figures quoted are based merely upon business judgment and are not worked out on a scientific basis. As a matter of fact, the basis is low and the yield will usually amount to much more.

John F. Carll, in Report III (Second Geol. Surv., Pennsylvania), on 'Progress of Oil Regions', gives the following estimates in support of his statement that an oil sand contains from one-tenth to one-eighth of its bulk in oil. These estimates can be applied generally to the sands of the Robinson fields, although they originally had reference to the Venango group of sands in Pennsylvania:

SUPERFICIAL QUANTITIES.
43,560 sq. ft. in an acre.
27,878,400 sq. ft. in a sq. mi.
6,272,640 sq. in. in an acre.
4,014,489,600 sq. in. in a sq. mi.

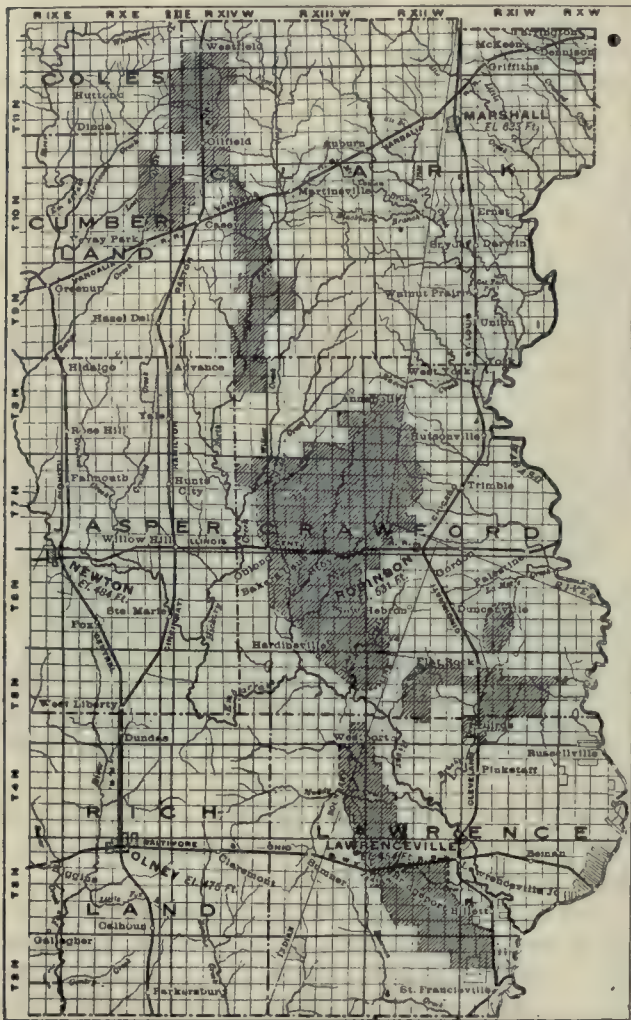

CUBICAL QUANTITIES.
9,702 cu. in. in a bbl. of 42 gal.
5.6146 cu. ft. " " " "

PRODUCTION OF OIL PER ACRE.
646.53 bbl. if the sheet of oil be 1 in. deep.
1293.06 " " " " 2 " "
1939.59 " " " " 3 " "
4997.68 " " " " 7.73 " "

PRODUCTION OF OIL PER SQUARE MILE.
414,779.65 bbl. if the sheet of oil be 1 in. deep.
827,559.30 " " " " 2 " "
1,241,338.95 " " " " 3 " "
3,198,515.20 " " " " 7.73 " "

On this basis 15 ft. of good oil-bearing sand would have a producing capacity of 15,000 bbl. of oil per acre or 9,600,000 bbl. per square mile.

With the lease secured, the operator must choose the site for his first well. It is the custom to place wells about 200 ft. in from a property line. This varies, however, with different depths of sands. In the shallow Casey pools of a depth of about 450 ft., instances are known of wells being put down 100 ft. in from the property lines. In the Robinson or Crawford county fields, where the sands are about 950 ft. deep, the location line is 200 ft. in, while in the Lawrence county field, having the sands at a depth of 1300 to 1800 ft. deep, the lines are 250 to 300 ft. in. In the Casey pool and Crawford county pool, wells are usually put down 450 ft. apart, while in Lawrence county where the wells are pumped from the Buchanan, Kirkwood, and Tracy sands, the locations are 660 ft. apart. Certain circumstances govern the placing of wells aside from mere distance. If there is a sudden dip of the sand around a regular location, the well is shifted to meet the conditions as judged by the operator. He considers also permanent power-houses, irregularities of surface,

Oil Pools in Eastern Illinois.

erty, and with wells in operation is often sold for a large amount. A transfer often takes place even though there are no wells drilled on a leased farm. The chance of this is dependent upon the distance from good territory. The sale of oil properties is often made by payment of a lump sum without estimates of future production, but more often the price is gauged by an estimate of the quantity of oil per acre per well. This in turn is dependent upon the thickness of the sand and the daily production of the well. For example, it is roughly estimated in the Illinois field that a well producing 10 bbl. per day from 10 ft. of sand will yield 2000 bbl. per acre. It generally, under these conditions, draws oil from six acres, and consequently would yield 12,000 bbl. If

and buildings, in his choice of a well-site. Again an operator will put down wells that are based upon the relative production of neighboring wells. An unwritten law exists that a lessee shall drill whenever producing wells are found on adjoining properties. This is called 'offsetting', and is done to protect property lines and drainage of oil from the lease. Should there be wells completely surrounding the tract, the best plan is to offset all adjoining wells and only drill along property lines, leaving the

dependent upon the locality and depth of sand to be reached. The contract stipulates for drilling a certain number of feet and the contractor is responsible for the well to the extent of reaching the sand and determining whether it is producing. The operator, on his part, usually agrees to furnish all conductor, drive-pipe, casing, tubing, and rodding, and is to secure and pay for the teaming in the transportation of the pipe. The contractor is held responsible for the purchase and construction of the rig. He furnishes his power, boiler, and 'string of tools'. He contracts and pays for all fuel and water used. He employs the drillers and tool dressers and is held responsible for all accidents. He also must clean out the well, put it in order, and pull the casing after a successful shot. It is furthermore generally agreed that drilling shall begin within a certain time from the date of the contract.

With the contract signed, the operations pass into the hands of the contractor, who in turn contracts with the 'rig-builder' or man who constructs the rig.

Drilling With a Mast.

centre to draw upon. It has been found that there is no necessity for putting in centre wells, as the line-wells draw longer and to much more advantage. Moreover, it is an unnecessary expense to put in an extra well in a forty-acre tract or three extra wells in an eighty-acre tract.

It is a difficult matter to estimate the acreage drawn upon by oil wells. This is dependent upon the depth and porosity of the sand, the area of the pool, and other factors. In the Casey pool in the northern end of the field about eight acres are assigned to each well. In the Crawford county pools, six acres are considered an oil unit, while in Lawrence county, where the locations of the wells pumping from the deep sands are farther apart and the sands are more prolific, ten acres is the area drawn upon. In the Casey and Crawford county pools twelve to fourteen wells are drilled on an eighty-acre tract, while in the Lawrence county field eight to ten wells are drilled to every eighty acres. These figures take no account of centre wells.

The next step, after choosing and marking a location, is to contract for the drilling. An agreement is drawn up between the operator and the contractor calling for the drilling at a certain price per foot.

Standard Rig as Used in Illinois.

Practically all rigs in the Illinois fields, outside of the Casey field, are of the Standard type and consist of four strong uprights, held in position by ties and braces. They rest on strong wooden sills, which are preferred to masonry. The derrick is used as a support for the sheave called the crown pulley, which must be at a sufficient height to swing the long heavy drilling tools free from the ground. The average height of the derrick is 66 ft. for the shallow fields

and 72 ft. for the deeper fields. Oil derricks are of a peculiar type and are conspicuous features of the landscape. In the shallow fields a combined portable rig and drilling outfit is used. These machines are of two types, the Star and the Parkersburg. Their cost for all equipment necessary to drilling is about \$2300. They are not, as a rule, entirely practicable in the deeper territory, and where hard materials are found at depth. With the standard derrick are included under the term 'rig' all the woodwork and necessary iron fittings, so arranged and put together that when boiler and engine are in place, drilling can be begun at once. Other important features of the derrick are the bull-wheel and shaft on which the cable supporting the drilling tools is wound, the walking beam, to give vertical motion to the tools, and the band-wheels for transmitting power from the engine to the movable parts. These parts of the equipment are covered with sheds for protection from the weather.

The construction of the rig requires about three days. In the Illinois fields the price paid for the rig complete and new is \$500. After the well is completed the structure is, in most cases, torn down and re-used. The cost of tearing down and re-building is about \$60. It costs the contractor about \$40 additional for new lumber, nails, repairs, etc.; thus placing the total cost for its second or third use at about \$100. It is estimated that the original derrick can be used ten or twelve times. In case a well must be cleaned out, a light portable rig for this purpose is used.

In 1906, during the opening of the field at Casey, the cost of drilling was \$1 per foot, when fuel or water were not included, and 90c. per foot when they were. Since that time the extension of drilling into deeper sands has changed conditions. The following costs are now representative:

| | Cost per foot. |
|---|----------------|
| Casey sands, 450 ft. deep..... | \$0.80 |
| Crawford county, 900 to 1000 ft. deep, in 1907.... | 1.00 |
| " " " " " " 1908.... | 0.90 |
| " " " " " " 1909.... | 0.80 |
| Lawrence county: | |
| Bridgeport sand, 950 ft., with 10-in. drive-pipe and 6¼-in. casing..... | 0.90 |
| Bridgeport sand, with 16-in. drive-pipe and 8¼-in. casing | 1.35 |
| Buchanan sand, 1350 ft. deep..... | 1.35 |
| Kirkwood sand, 1500 ft. deep..... | 1.50 |
| Tracy sand, 1700 ft. deep..... | 1.50 |

The Bridgeport sand was the first one developed in Lawrence county and was drilled by the methods used for reaching the Crawford county sands of the same depth. Later when the deeper sands were discovered and found to be more prolific, it was learned that bores could not be put down to advantage to the lower sands through a 6¼-in. casing. To secure production from all sands, therefore, a larger size drive-pipe and 8¼-in. casing were introduced. This is the almost exclusive practice today for new wells. Where old wells with smaller casing are already down to the upper sands and companies wish to extend them to the lower sands, new holes are drilled. This is frequent north of Bridgeport. South of the town the wells are mainly new and one set of casing does for all sands.

In work in this territory the drilling crew consists of four men, two drillers and two tool dressers, who work in pairs and in shifts of twelve hours each. It is the duty of the driller to stay close to the mouth of the bore, turning the cable and the temper screw when necessary. He controls the machinery by cords or by levers when changing the tools and in sand pumping. The tool dresser helps the driller. He fires the boiler, attends to the engine and machinery, and dresses or sharpens the bits as each in turn becomes worn. Drillers in the Illinois field in 1909 were paid \$5 per day and tool dressers \$4. The time required in the different pools for drilling, shooting, cleaning, and putting a well in order, is as follows:

| Pool. | Days. |
|------------------|----------|
| Casey | 4 to 5 |
| Robinson | 14 to 15 |
| Bridgeport | 14 to 16 |
| Buchanan | 30 |
| Kirkwood | 45 |
| Tracy | 55 |

As soon as the oil-bearing stratum has been tapped and a reasonably fair production has been determined by the use of a bailer, the work is continued into the sand to within a foot or two of the bottom or until evidence of salt water appears. The well is then torpedoed or shot with nitro-glycerine, in order to make open fissures in hard rock and to form a cavity in softer sand, into which the oil may seep or flow. The shooting is gauged so as to form a hole within the oil-bearing sand and not disturb the overlying formations, usually shales. If these be loosened, they fill the cavity with debris and makes the work of 'cleaning out' exceedingly difficult. The size of the shot is dependent upon the texture of the rock and the thickness of the sand. In Clark and Crawford counties the sands are shot within 3 ft. of the top, while in Lawrence county the deeper sands are torpedoed within 5 to 10 ft. of the top. In the former counties a 5½-in. shell 5 ft. long, holding 20 quarts of explosive is used. In the deeper fields the same shot is used in the oil-sand proper, but in the bottom of the sands, 1½-in. shells are used in multiple as an anchor. These are loaded and placed around the hole at the base of the sand. At intervals of 10 to 15 ft., one of them is loaded with explosive in order to insure an even transmission of the force. The use of the thin shell is to protect the upper sand from as much debris as possible and to insure a safe explosion in the sand. The average shot for the whole Illinois field is from 80 to 100 quarts. This has been found adequate for all sands. The old custom based on the rule 'the larger the shot, the better the well', has been discarded as extravagant, and large shots are now only used in cases of hard sands or exceptional depths of pay-sand. The shooting is done by agents of the manufacturers of the explosive, who are employed at a salary, approximately \$100 to \$115 per month. In Clark and Crawford counties, the shooter is responsible for the well from the moment he takes charge of it. If through neglect or carelessness a premature shot occurs and ruins the well, the shooting company must immediately arrange to drill another on the same location. If the shot is successful the contractor resumes charge of the well and completes it by cleaning out and putting it in order. The

conditions are different in Lawrence county, where trouble is experienced by the disposition of the formations immediately above the oil-sands to cave. The oil company and the shooter work together and a shot is lowered with the utmost care. Often a cave-in of the shale happens before the shot is exploded, and in that case the company cleans out the hole very cautiously to the top of the shot. As in the northern end of the field, the explosive manufacturers are responsible for loss by a premature shot caused by neglect, but not for loss due to such a cave.

The torpedo companies have local plants for the manufacture of nitro-glycerine. These are situated in isolated spots near the field, one for each general pool. At other out-of-the-way places in the field there are maintained small storage houses. From these points the nitro-glycerine is hauled overland by the 'shooters' in light wagons, fitted with strong but flexible springs. The wagon-bed is arranged with square padded cells for holding ten-quart cans. Upon the outside of each wagon there is printed in large letters 'Nitro-glycerine, dangerous'. The approach of a glycerine wagon upon the highways is a signal for apprehension to most travelers, who are generally surprised to note that the driver trots by without the slightest concern for bumps in the road. As a matter of fact there is little danger when the outfit is in charge of a careful man acquainted with the nature of the thick whitish liquid. The writer has frequently ridden on the 'dangerous' wagon, only to find all apprehension quickly dispelled in admiration of its easy riding. Accidents are rare and are due to a collision of some kind or to carelessness in pouring the liquid into the cans. If a drop or two is allowed to get on the outside of the can, it gives opportunity for explosion through friction. The liquid is very viscous and is easily poured by a steady hand.
